Rossiville asylum, N.S.W., plan, 849
Rotherhithe town hall, 408
Royal: galleries, pictures in (Brussels) 372, 558, 630, 780, 883 (Dresden) 264; institute, British architects, silver medal drawings (J. H. James) 46, 116, 152
Rushden, warehouse and baths, 537
Rydal Mount schools, N. Wales, gymnasium, 353

SAINT: Aignan (Chartres) 702; Andrew (Chartres) 702 (Fulham, parish room) 736, 737, 738; Charles (Antwerp) 808; Chiara (Florence, altar from, S. K. M.) 476; Esprit, mantle and baldaquin of, order of, 78; Francis de Sales (Tottenham, R.C.) 556; Hubert (Amboise, chapel) 12; John's, Woking (Eventyde house) 336; Joseph (Highgate, R.C., sanctuary decoration) 336; Lawrence (Barton) 558 (Ogdensburg, state asylum) 735; Loup (Namur) 808, 809; Maria della Pace (Rome) 295; Marylebone (public baths) 702; Michael (Beguildy) 852 (Gloucester) 226; Nicholas (Blois) 12; Paul (Covent Garden) 915; Paul's cathedral, north-west tower) 917; Peter and Paul (Llandaff cathedral) 46; Peter (London Docks, font canopy) 885, 903 (Rome, details) 404, 405; Philip Neri (Rome, oratory, fireplace) 474; Pierre (Caen, details) 554; Spirito (Florence, cloister) 405
Salisbury cathedral, Bishop Bridport's tomb, 152
Sanctuary decoration, St. Joseph's, Highgate, 336
Schools: Hull (Wesleyan) 152; Londonderry (Pesbtn.) 740; Newcastle-on-Tyne (board) 702; Oldham (Hulme grammar) 12; Pyrton (mixed) 283; Richmond, Surrey (secondary) 152; Rydal Mount, N. Wales, 353; Tonbridge (chapel of) 78; Tulse Hill (Presbtn.) 482; Tunstall (bd.) 558
Scientia water closet, 649
Scott's (W. B) "Temptation of Eve," 702
Screens: Merchant Taylors' hall, 588, 589, 630; organ console, Coats ch., Paisley, 446; Rochester cathedral, 852; south transept, Gloucester cathedral, 226
Secondary schools, Richmond, Surrey, 152
Secretaire, 683
Sections: barracks, designs for, 626, 627; baths (Brentford) 482; bungalow, riverside (club designs) 46; cathedral (Llandaff) 46, 116, 152; chapel (Tonbridge school) 78; concert halls, 693, 737, 738; dairies, designs (C. A. Callon) 740 (C. A. Battie) 740 (A. and H. Fenning) 780; fire brigade station (Belfast) 372; fireplace (Hutton Court) 12; house, country (club designs) 814; Ionic base and cap, 9; libraries, free (Hammersmith) 12; rooms (Willis's) 906; siphoned branches for gullies, 920; staircase (Rome, Berberini palace) 475; theatre (Glasgow) 391
Self-lighting gas-burner, 95
Settle, American, 683
Settlement buildings, Passmore Edwards, Tavistock-place, 189, 190, 209
Shanklin church, lych gate, 251
Shepherd's Bush, Passmore Edwards free library, 12
Shoreditch baths and free library: 1st design, H. T. Hare, 852; 2nd, A. H. Tiltman, 886; 3rd, Groll and Todd, 922; F. J. Smith, 922; Spalding and Cross, 922
Sideboard onts., nat. silv. med. design, H. D. Richter, 780, 797
Siena, Spannocchi palace, 184
Simon the Pharisee, Christ and, 372
Siphoned branches for street gullies, 920
Sketches: furniture, 114, 281; in Chartres and Normandy, 702; Loire valley, 12; Rochester cathedral, 630, 852
Soane medal design, picture gallery (H. Jefferis) 702
Sodbury, Little, manor house, 5
Soldiers' barracks, designs for, 626, 627
Solothurn: concert hall, 369, 372; museum, 368, 372
Southall, margarine works, 309, 319
Southampton, dining-hall, 885
South Kensington museum: altar, Sta Chiara, Florence, 476; chimneypiece and panel, from Lime-street, 879, 880; doorways, palace (Genoa) 476 (Gubbio) 477; Early French furniture, 114; Etruscan antefix, 72; fireplace from Brittany, 407; rood loft and crucifix, 520, 555; "Temptation of Eve," by W. Bell Scott, 702; wall fountain, Florentine, 510
Spalatro, palace of, arches, 147
Spannocchi palace, Siena, 184
Spongy iron, 661, 662
Staff, pastoral, Gloucester museum, 226
Staircases: Boston, Mass., 647; Goddington, 372; country house (W. H. Ashford's design) 372; Mercers' hall, 666; Rodway manor, 4; Rome, Berberini palace, 475; Sydney, Equitable assurance offices, 78; *Tantallon Castle*, 149
Stanton: doorway of house, 190; village and cross, 190
Stanway: church, 190; hall (courtyard, plan) 181 (gateway and details) 190
Station: fire brigade, Belfast, 372; hotel, Fort William, N.B., 630
Steel bridges, designing of, 136, 254, 355, 443, 663
Stonehenge, sketches at, 479
Street: corner in Mayence, 843; gullies, siphoned branches for, 920
Stresses: graphical determination of, 700; in roof trusses, 873
Striking centres of arches, 38
Strozzi palace, Florence, 184
Students' training wards, in asylum, 297
Study, a, in the roof (R. Barry Parker's design) 99
Sudeley castle, 226
Sword bracket, Vintners' hall, 336
Sydney: assurance offices (Equitable, U.S.A.,) 78 (New York Mutual) 408; Callan-park asylum, 777

TABLES, French, 114 (money changer's) 281; wall, 683
Tantallon Castle: music-room, 148, 149; staircase, 149
Tavistock-place, Passmore Edwards Settlement buildings, 189, 190, 209
Taylors, merchant: hall, 587, 588, 589, 594, 630, 740, 814; school, headmaster's house, 885
Technical institutes: Richmond, Surrey, 152; West Ham (selected, Gibson and Russell) 482, 520 (2nd, Clark and Hutchinson) 520 (3rd, T. Davidson) 520 (S. Beale) 594
Temples: Clontarf (by Sir W. Chambers) 558; Ephesus (Diana, details) 8, 41, 72; Erectheium (Caryatid) 9 (frieze) 73; Rome (Jupiter Stator, console) 135 (Mars Ultor, details) 72
"Temptation of Eve," by Bell Scott, 702
Tewkesbury: abbey, sketches in, 226; timbered houses, 218, 251
Theatre: Glasgow, 391; Rome, Marcellus, tiers of arches, 146
Threadneedle-st., E.C., Merchant Taylors' hall, 587, 588, 589, 594, 630, 740, 814
Tilbury cottage hospital, 594
Tithe pot, Cluny museum, 558
Titus, arch of, Rome, Composite capital, 40
Tombs: Arlington's, Rolls chapel, 881; Bishop Bradfield's, Rochester cathedral, 852; Bishop Bridport's, Salisbury cathedral, 152; John Gibson's, Kensal-green cemetery, 780
Tonbridge school chapel, 78
Tottenham, St. Frances, R.C. church, 556
Touraine, sketches in the, 12
Towers: Barcelona cathedral, 336; Gloucester (St. Michael) 226; St. Paul's cathedral (N.W.) 917
Town hall: Audenarde (door) 807; Cologne, 842; Rotherhithe, 408
Training wards, at asylums, 297
Triforium, Gloucester cathedral, 226
Trivet, Cluny museum, 575
Trusses, roof, stresses in, 873
Trut hall, near Helston, 630
Tufnell-park, pair of houses, 425
Tulse Hill Presbyterian church, 482
Tunstall, High-street board schools, 558
Tynemouth priory, 213

UNIVERSITY: college, Aberystwith, hall of residence, 254; Glasgow, medical department, 740; Padua, arcade, 404

VALLEY, Loire, sketches in the, 12
Valmarana palace, Vicenza, 258
Venetian: caricatures in alabaster, 814; paintings, 594
Venice, library, 295
Ventilator, Hill's new, 76
Verona: Bevilacqua palace, 295; Carnossa palace, 295
Vicenza, Valmarana palace, 258
Villas, East Grinstead, 869
Vintners' hall, master's chair and sword bracket, 336
Vire, la porte Horloge, 702
"Virgin and Child," by Memlinc, 886
Vlaenderbergh, Barbara van, Memlinc's, 630

WALL: cupboard, Haberdashers' hall, 336; fountain, Florentine, 510; table, 683
Warehouses: Belfast, 46; Rushden, 537; Southall (margarine) 300, 319
Warwick chapel, Tewkesbury abbey, 226
Washington, loggia at Metropolitan club, 831
Water: closet, Scientia, 649; gate, design for (G. Lacy) 300
Waxwell farm, Pinner, drawing-room, 408
Weaver's house, Ghent, 372
Well head, Maison Fontaine Henri, 711
West Ham: casket of freedom of, 549; technical institute and free library (1st design, Gibson and Russell) 482, 520 (2nd, Clark and Hutchinson) 520 (3rd, T. Davidson) 520 (S. Beale) 594
West Norwood, Presbyterian church, 482
Westminster: banqueting hall, Whitehall, 916; from the river, by Canaletto, 594; old Houses of Parliament, 264
Whitehall, banqueting hall, 916
Wickhamford church, details from Sandy's tomb, 190
Willis's rooms, plans, 903
Winchcombe, old houses at, 226
Wind pressure on ogee roof, 835
Windows: dining-room, American cottage, 264; Settlement buildings, Tavistock-place, 209
Wing, new, Park hall, Oswestry, 12
Woking, Eventyde house, St. John's, 336
Wolstanton board schools, Tunstall, 558
Woodford, Essex, house at, 78
Worcester, old houses in Friar-street, 300
Writing bureau, 683
Wrought iron work, Coats church, Paisley, 446

XANTHOS, Nereid monument from, 41

YARROW convalescent children's home, Broadstairs, 171
York: gate and Westminster, Canaletto's, 594; new buildings, Duncombe-place, 336

THE BUILDING NEWS
AND ENGINEERING JOURNAL.

A FIELD FOR THE SKETCHER.

If we were to say that the great majority of architects habitually leave out of sight one of the most effective sides of the art they practise, and if we were to add that an immense number of students, and even of artistic ones, follow their example, we should scarcely go further than facts would warrant. Yet this neglected side is not only a most attractive, but might be a most popular one. In some phases of style, and those the most refined, it has been the side to which the architect mainly trusted for success. Though it is capable of any amount of elaboration and costliness, it does not insist on them. It crowns all other details in palaces and cathedrals: it makes up for the want of all others in cottages and sheds. Nature is teaching it by direct example all day long. Earth and sky and sea cry aloud about it, though few regard them; and it is only amongst buildings that a human being could pass his life without ever being reminded how glorious a thing is colour.

For this neglect there are several reasons. It is not long since many good people thought colour sinful. They were not the first, and will not be last, who aimed at sanctity through singularity. The way looks so tempting. To be better than one's neighbours, more honourable, more benevolent, more unselfish is difficult; to dress in drab and revel in whitewash is easy. To believe, and to make others believe, that goodness consists in things like the latter, and not in things like the former, is to stake out a royal road to perfection, with no hills, no stones, no quagmires in it. It was a road which a great many people followed in the early half of this century, and which is far from deserted yet. But it is not probably a road much travelled by architects, though the footsteps of the illustrious Pecksniff may still be traced there. Others, when they come within its borders, are perhaps rather taken there by their clients than urged by any preferences of their own. If they neglect colour, at least they do not claim this as a virtue: their work happens to lie in quarters where colour is still practically prohibited.

On the other hand, a great many persons who never troubled themselves about the supposed wickedness of colour, have, in the course of the last two or three centuries, prided themselves on their aversion to it for other reasons. They have held it to be vulgar, impure, or, in other words, contrary to Classic precedent. We know now that old Greek and Roman art was full of colour. Not only did it employ all sorts of coloured marbles and gems, which ancient writers describe, and which even time has not wholly destroyed, but it revelled in surface decoration, both on walls, floors, ceilings and sculpture. This fact, however, has only been found out by slow degrees. When the remains of ancient art were first studied, about the end of the 15th century, the great bulk of this adornment had perished. A thousand years of destruction or neglect had worn away everything but the marble itself, and it was taken for granted, then and long afterwards, that with beautifully-shaped marble works, Classic art had practically begun and ended. As the ancient temples and statues were more and more studied, it became more and more the rule to try and copy them exactly. No colour being perceptible without close scrutiny on the old ones, it was held an artistic crime to put any on the imitations. It thus became a primary article of the orthodox creed that the Greeks and Romans loved to surround themselves with bare white marble, as lifeless and cheerless as the ice of which a palace was once built at St. Petersburg. Nothing else was pure; nothing else was proper; nothing else was in good taste. So every gentleman who had received a classical training, felt bound to condemn all colour as an abomination, and if he could do no more, at least he whitened his parish church, and took the stained glass out of the windows.

The antiquarian blunder and the moral one supported each other. The hatred of colour became at once a proof of refinement and a token of virtue; and so it has happened, that from the time of Charles I. till now, Englishmen have almost allowed one of their faculties to perish by disuse. How far it had failed became manifest some five-and-twenty years ago, when, going from one extreme to another, a passion seized so many architects for "polychromatic decoration." It was as if a sudden fit had come on a roomful of people who scarcely knew their notes, for performing an oratorio they had never even tried to practise. The discords were frightful. The thing threatened to be a public nuisance, and the performers abandoned it. "Polychromatic decoration" no longer shows itself in street fronts. But the failure does not prove it wrong. There is a place for it, as there is a place for an oratorio. What the failure proves is, that complex things in colour, like complex things in music, need skill and study. It is necessary to begin at the beginning, and to master the art by degrees.

How is it, then, that so few students are apparently trying to master, not only elaborate systems of colour design, but even those elementary ones which are indispensable to everybody who builds? One answer is, that in this age of examinations, it "does not pay." The young architect, with more subjects forced on his attention than any young man ever had before, is obliged to make a selection. He has to neglect those which are, in comparison, worthless, and, not unnaturally, he feels that "the worth of anything is just as much as it will bring." The study of colour will not bring him much in examinations, though it may do more for him in after-life. But his examinations are pressing, and his subsequent career is at a distance; so he puts off the matter to a more convenient season. He grows older and goes in, perhaps, for competitions. But here, again, by the wisdom of committees and assessors, colour is strictly prohibited. In this quarter, therefore, it still "does not pay." He starts in practice, and roused at last by some suggestive lecture at the Institute or the Association, he feels that his opportunity has arrived. His first building shall be a triumph, not only in design and construction, but in colour also. The principles he has heard seem so easy of application, and so pleasant too. Structural questions will not trouble him here; points of practical convenience will refrain from interfering; even the district surveyor himself can be set at defiance. But the young architect finds that this branch of its profession, like the rest, has perils of its own. He has been taught, for instance, how to combine or to contrast his yellows and reds and greys; but when he comes to do it, he fails to get the right yellow, or the right red, or the right grey for his special purpose. If at last he gets the right one, his workmen cannot match it, or, if they do, it turns out to be too pale or too dark for its place. He makes acquaintance with the colour-blind painter,—that everyday product of our civilisation,—and with that still commoner one, who wants to put chrome yellow and French ultramarine into everything. Then the effect of distance upsets his calculations. The changes of light from dawn to sunset play all sorts of tricks with his scheme of colour; the lime of the plaster eats into it, and the wall surface which was purple in the morning has transformed itself to a lively green by the afternoon. The end is that he distempers half his decorations over, with some wash "warranted to stand," and that thenceforth he is very shy of trying others like them.

All this means that, as a colourist, he has set up for a master before being an apprentice. The suggestions of an accomplished decorator are valuable to those who have practised decoration, but they are no substitute for training and observation. Without these things, an architect may attain a certain success by turning over his elaborate colour-schemes to capable men who make a speciality of them. But whether he desires it or no, he has to do with colours throughout his work. His architecture will depend greatly on his materials, and his materials will form, in combination, either a good colour system or a bad one. If he leaves it to chance, it is pretty sure to be the latter. Yet he too often does leave it so, and either spoils good detail, or makes bad detail worse. Unless he is naturally destitute of an eye for colour, he might do better than this with very little labour to himself.

"What shall I sketch?" is the question which recurs every year at this season. To those who naturally love colour, we would reply: Try for one holiday the sketching of colour. Take a small moist-colour box and a couple of water-bottles, and make a set of simple memoranda of all the colour combinations which take your fancy. They are to be found everywhere, outside our great cities, and sometimes even in them. There are the varied colours of building stones, some as striking as those of marble, but almost unknown, like one that is in use near Banbury. Then there is the red stone of Coventry and Kenilworth, the bluish grey of Dean Forest, the orange and brown and white of Ham Hill, the brighter reds and blues of South Devon, the silvery granites and deeply stained porphyries of Cornwall, the bricks and flints of the Eastern counties. Mark what goes best with each in the way of tiles or slates, or wood, or paint, or plaster; and mark it, not in words, but in actual tints. Note in the same way all beautiful harmonies or contrasts in flowers, or buds, or insects, in tints of sky or water, or fading leaves, and you will have a series of definite facts as a foundation, whether your decorative attempts in future are simple or complex. Your sketches will not make much show. They cannot well be illustrated in the architectural journals, and so far, your friends who go in for draughtsmanship will have a temporary advantage over you. But they will be things to fall back on all your life—definite statements, compared with which, mere words are worthless; guides which, on a thousand occasions, may keep you from going wrong, and counsellors who will put you in the right road for gaining a thorough knowledge of decoration, should you end by studying it more completely.

REASONABLE SKILL AND CARE.

THE phrase "reasonable skill and care" is so often used in a legal sense, and so much turns upon its meaning in the discharge of the architect's functions, that it may be worth while asking what it implies in the ordinary duties of the practitioner. When an employer claims damages from his architect for negligence or want of skill, he has to prove by attested witnesses the truth of his allegation, and, of course, this is a question of expert evidence. It is not an arbitrary or fixed measure of skill, but sufficient under the circumstances of each case, which varies, as a matter of course. For example, in the design of a hospital, it would be reasonable to suppose that the architect planned his sick-wards on principles that were generally recognised; that the sanitary provisions were sufficient and convenient, that the heating and ventilation were devised upon good models. If he failed in any of these points of plan or provision, he could not be said to have shown reasonable skill. Mr. Brown is a good general house designer, but has had no experience in the planning of a free library. Would it be just to charge him with having failed to carry out the requirements of the committee? Here the question of limited experience might be urged; that the promoters knew beforehand Brown had no experience in building libraries, and that they could not therefore expect him to exercise a high degree of skill in the design or plan. Such a view of the matter has been held by judges and juries, they holding that "reasonable skill" must be interpreted in a limited sense in such a case. But there is a presumption that every professional man represents himself as possessed of the requisite ability and skill. When an architect is employed to carry out any building, no matter of what description, and he undertakes the work, there is an implied warranty on his part that he is reasonably competent to the task. And this is the general and reasonable view. Mr. Tompkins, the architect, who undertakes to design Mr. Smith a house or a shop, is supposed to bring to his task all necessary knowledge and experience, and, on his part, Mr. Smith expects all that he has bargained for, and certainly holds Tompkins responsible for any defects in design or negligence in superintending the building. If it were not so, an employer might just as well engage a builder or a foreman of works to carry out what he wants in his own way. In the same manner a man who was suffering from illness or some malady might save the cost of a doctor's fee by going to an apothecary, and would be himself to blame if by mischance a wrong medicine was given him. On the other hand, if he went to any registered medical practitioner—whether or not he was a specialist matters little—he would be justified in assuming that his case would be treated with a certain or reasonable amount of skill, or that, at least, his competence for the task would be assured him. If it was an eye or throat trouble, the general practitioner would, at least, prescribe safe measures that were generally followed; or, if it was too complex a case, would at once recommend his patient to go to an hospital or consult a specialist. And so the professional architect is presumed to understand the requirements of any particular building he undertakes—so far, indeed, as to protect his client against loss or damage.

One of the frequent charges brought against the architect is that of under-estimating. A client has a right to expect a certain degree of accuracy in the estimate he receives, and if he prescribes an outside limit of expenditure, he has reason to be dissatisfied if the lowest tender exceeds that limit to any large extent. A reasonable approximation to the actual cost is certainly a question of skill. When the contract sum exceeds, say, by 30 per cent. the architect's estimate, it can hardly be said that reasonable skill or care has been exercised, unless, of course, as often happens, additions, changes, or alterations have been made during its progress. Estimating is certainly one of those branches of architectural practice about which a certain degree of skill is looked for. The Law Court reports afford ample evidence of what is expected from the architect. No doubt the profession are great sinners in this respect. The exceeded estimate is a common reproach levelled against architects, but that is no reason why they should be content to bear the brunt of a charge which is damaging to their interests, and which in many instances can be avoided. An architect is blamed for many things which are not to be placed to his charge. For instance, he cannot foresee the nature of the soil on which his building is reared. When the digging for foundations is begun, it often turns out that they must be sunk to a greater depth than shown or specified, and expense of concrete or even piling may be incurred. The architect is blamed because he has not foreseen this and provided for it. His estimate has been based on a superficial examination, or on borings that have been supplied him; these turn out misleading, and his charges are disputed because he neglected to make a more thorough personal examination. In one or two cases cited the architect has failed to recover on this ground. But such charge can scarcely be said to be due to want of skill: it is merely an excusable omission on his part, which may be made up at any time without incurring loss.

Then we have supervision. What is a reasonable amount of supervision, will always be a very debateable question, because some people are apt to think that every part of the building should be inspected and approved by the architect; while his notion of his duties is that he gives only a general supervision, and is not responsible for such things as improper bricks in any conceivable situation, or the stone to be laid on its natural bed in every part, nor is he responsible for the laying of drains underground or their proper jointing. The charge of want of skill or negligence may be raised by an irate client in several ways. There may be mistakes in the design, in the use of materials, and it is for every architect, in the particular circumstances in which he is placed, to avoid these as far as he can. Want of skill in design is again a question depending on the evidence of experts, which may vary. Conceptions of plan, for example, would be difficult to define in many cases unless there was some glaring omission, or some self-evident want of skill—as, for instance, a hall with inadequate means of ingress and egress, a too-narrow main entrance, cramped or dangerous staircase, a dark corridor. Want of skill would arise if an architect planned a block of offices with windows too small for giving adequate light, or without considering the right of the dominant adjoining owner to obstruct. A court of law will assume, naturally, that it is the duty of an architect to make himself familiar with the law of easements, such as those of light and air and support, as his ignorance of the law may involve his client in serious litigation and loss. Examples of such cases abound in our columns of "Legal Intelligence." Every architect is presumed to know so much law as will be necessary to protect his client's interests. There is no excuse for a professional man in London or elsewhere if he blunders in not complying with the Building Act or by-laws, and thereby puts his client to needless expense. The law will not excuse him by pleading ignorance of its provisions.

So also with respect to other matters than those directly connected with his profession. There is no excuse for him to plead ignorance of engineering. He cannot plead that he knew nothing of treacherous soils or the substrata of the site if the foundations give way and the building settles, or that it was a technical matter outside the architect's work. If he did not know how to provide for wet sand or clay, or what engineering expedients to adopt, such as piling, or planking, or coffer-dams, he should have called to his assistance some one who did. Again, if through defective design an iron girder gives way, precipitating a wall, or an iron roof collapses, causing serious injury, it will not do for the architect to exonerate himself and lay the blame on the engineer. If an arch fell in from want of sufficient abutment, as shown by scale on the drawings, the architect would certainly be held liable, and the same if any wall or column proved too weak. Perhaps in questions like ventilation and acoustics there would be more difficulty in proving incompetence. We are not aware that any legal charge of incompetence has been made out against any architect because the ventilation of his building was bad, or because the acoustical properties of a concert or lecture hall were defective. These are matters about which there are conflicting view and theories. It may indeed be affirmed generally that the term "reasonable skill and care" could only be applied to those practical and definite matters relating to building which every architect is supposed to know, and not to questions of any speculative or doubtful kinds, about which opinions would naturally vary. A wider interpretation of the meaning of the phrase would be given by any jury in some cases where, for instance, the complexity of the building or its conditions rendered the architect not altogether responsible, and the phrase would bear a more

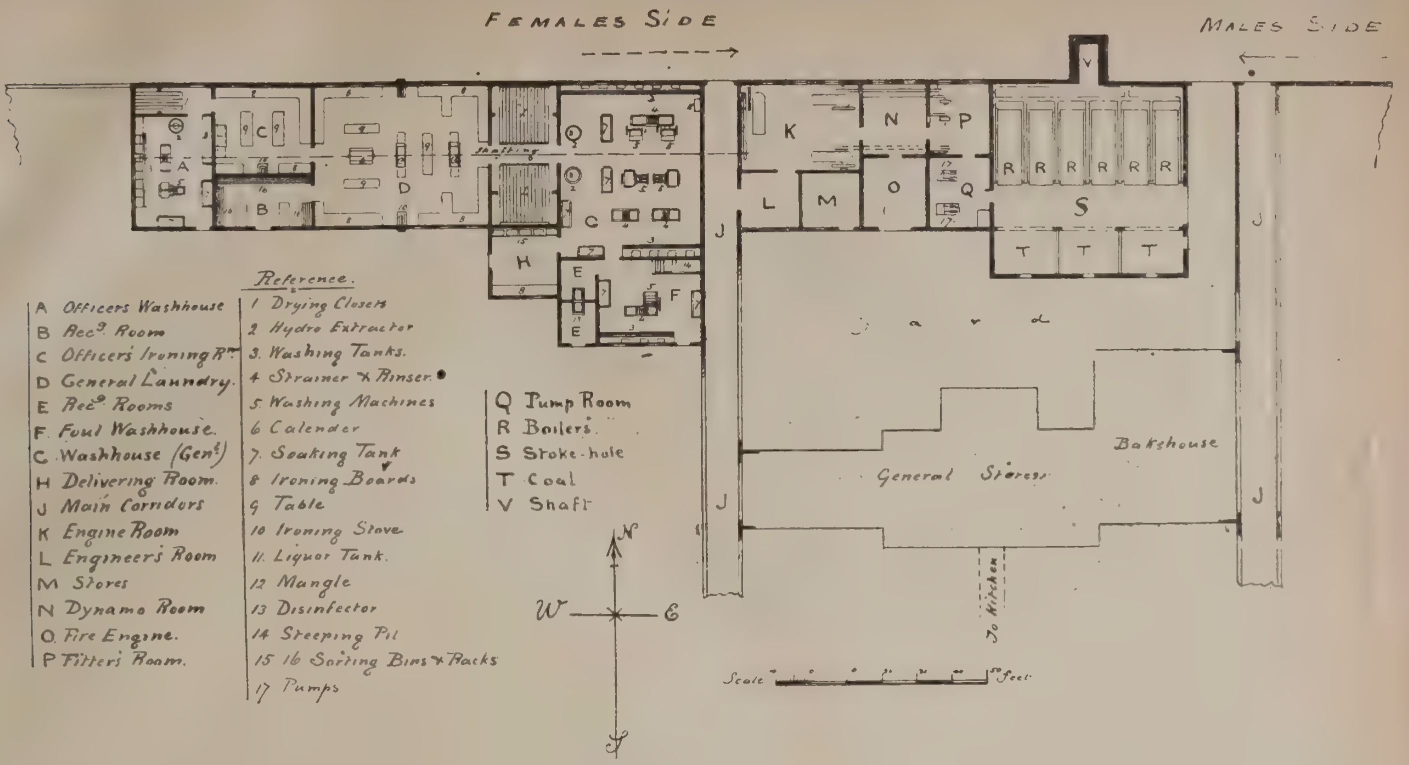

FIG. 37.

definite meaning in connection with buildings of ordinary size and everyday use.

COUNTY LUNATIC ASYLUMS.—XXI.

By GEORGE H. BIBBY, F.R.I.B.A.

ASYLUM LAUNDRIES.

AN asylum laundry should be different in many respects to the laundries for any other class of building, and the efficiency of this department is a most important factor as regards the health and comfort of the patients, for the special reason that a large number of asylum patients are very dirty in their habits, both by day and night. Employment in the asylum laundry has frequently great and special disadvantages as regards health and sanitary considerations; but, as a rule, the laundry stands in a similar position to the female patients that the workshops and farm lands, &c., do to the males, as regards opportunities for useful employment.

In the older asylums, and perhaps in many of more recent date, a great danger has existed with regard to fire, but the more modern asylums are so planned and constructed as to greatly minimise this risk; all hot pipes, flues, and fires should be isolated from woodwork, and, at all events, in large institutions steam-pipes are preferable to open fires.

Yet even with many of the latest asylums there are special fire risks for which the authorities have to adopt various precautions, especially in the ironing-room, where there must (under present conditions) be gas or fire-stoves to heat the irons, and where patients will also have easier means of reaching the burning coals or gas-flames, thus getting opportunities of doing mischief. Then, again, ironing patients may allow the irons and apparatus to become overheated (if not carefully watched), and are more liable than sane ironers to bring the linen, &c., into contact with the flames or red-hot surfaces, or to try overheated irons upon pieces of cloth and then throw the latter away in a smouldering condition. The ironing-room is frequently kept at a high temperature, and the adjuncts are, therefore, in a condition tending to the spread of any fire that might arise.

All this trouble and risk may be averted by the use of electrical appliances both for the washhouse and the ironing-room, the drying of the clothes being accomplished by means of electric drying closets, and the ironing by hand-irons connected with detachable wires to the electric mains. Some of these appliances are already in use in hotels and elsewhere, and I am strongly of opinion that the time is not far distant when electricity will be developed to such an extent in laundry matters that its use will entirely take the place of existing modes, when no ironing-stoves or fires of any kind will be required in connection with either the washing or the drying of clothes. The ironer would merely have to connect (instantaneously) the flat-iron with an ordinary electric cord, such as is generally in use with small electric lights; the iron would be quickly heated, and the heat regulated to a nicety without difficulty.

The drying of the clothes might either be by an electric fan, or by a direct application of electrically-produced heat.

In the construction of a laundry for an asylum, the superficial space to be allowed for each patient should not be less than 5ft.; therefore for an asylum for 2,000 patients there would be required 10,000ft. of area for the patients' laundry, which, however, would include an area of about 500ft. for the foul washhouse, unless there be a large proportion of patients with filthy habits.

In addition to the above accommodation there would be required a laundry area of about 1,500ft. for the officers and nurses, &c., preferably in a separate building, or apartment with separate receiving and delivering-rooms, &c.

It will be convenient here to take such an illustration of an asylum laundry upon a large scale, as is shown in Fig. 37, in which A indicates the position of the officers' and nurses' washhouse; B, the officers' ironing-room; C, the delivering-room from the general laundry; D, the general ironing and finishing-room; E, the general washhouse; F, the general receiving-room; G, the foul washhouse; H, the foul washhouse receiving-room; I, the engine-room; K, the engineers' room; L, fitters' shop; M, stores; O, the dynamo-room; N, fire-engines; P, the pump-room; Q, boilers; R, stoke-hole; S, coal-bunkers. The position of the various appliances is indicated by figures on the plan, and which should be supplied by firms having special experience of asylum laundries.

The construction of a large laundry of modern type is a vastly different affair to those in asylums erected some twenty or thirty years ago, and since the introduction of gas, steam appliances, and elaborate machinery for nearly every operation.

The walls of an asylum laundry should (at all events, to a height of 5ft. or thereabouts) be lined with glazed bricks or tiles of a light or white colour; the apartments should all be light and well ventilated. Many laundries are lighted only by skylights; but it would appear to be much more desirable that there should, in addition, be a fair supply of windows in the side and end walls. The floors of the washhouse may be either of tiles or cement, the latter for preference, and so dished, guttered, or inclined, that the waste water, soap-suds, &c., may be collected into receiving-tanks. The washhouse should be constructed so as to allow the washing troughs to face the windows, not only for purposes of light, but also to secure for the patient employed therein as much cheerfulness as may be obtainable.

To a very great extent hand labour should be utilised in an asylum laundry; but in the foul washhouse and elsewhere some washing machines would generally be required, and (with proper and sufficient protection from the asylum patients) steam-power would frequently be advantageous, the belting, &c., being driven from a shaft *below* the floor-level rather than above the heads of the workers, although circumstances may sometimes make the latter arrangement more convenient.

With regard to the machines to be employed, these must be chosen with special regard to the fact that the asylum patients engaged in working them should not have opportunities of injuring either themselves or the apparatus; and the latter should be as compact as may be, space being so valuable in this department.

There is a patent self-reversing washing machine that is made for steam-power, the dimensions of which (largest size) are 6ft. in the clear. It consists of an outer case with a revolving cage, actuated by pulleys upon the centre shaft, passing through the case. This central shaft is driven from a counter-shaft overhead, which is a component part of the machine, and is fitted with a set of automatic striking-gear, which by means of a crossed and open strap causes the inner revolving drum to *reverse its direction at every three or four revolutions*, thereby preventing the tendency of rolling-up and balling of the fabrics undergoing cleansing.

The revolving cage is, for convenience, divided into four compartments, and all the clothes in each of these compartments are passed through the washing solution at each revolution. The outer door in the case provides access to the inner drum, and a hand-shaft with worm and wheel arrangement is fixed on the side for bringing the door of each separate compartment to the position for discharging and filling opposite the door in the outer case. The lower part of the case is provided with an emptying valve, to run off the cleansing solution; hot water, cold water, and steam are laid on to the machine, so that it may be used either as a rinser or washer, or as a boiling tub or a disinfector, by turning the steam direct on to the clothes. Another type of this machine is made to resist pressure, and is fitted with a safety-valve, and these machines may be fitted with a vertical steam-engine as an integral part of the machine, so that where no line of shafting exists it has its own motive-power, with a sufficient reserve to drive a wringing-machine or mangle if required, or for doing other work.

These latter machines are suitable for asylums of moderate size, and are in use at the Herbert Hospital, Woolwich, and the Netley Hospital, Southampton.

The washing troughs may be made of 2in. wood, grooved, leaded and fixed together with lag bolts, having brass waste plugs and iron legs, and the inside measurement of each compartment may be 28in. by 25in. by 17in.; the height to the upper edges may be about 32in.

In an asylum for 800 patients (and for the officials and nurses, &c., having charge of them) the following are, approximately, the appliances for which space must be found by the architect:—

In the General Laundry, one hydro-extractor 36in. in circumference; one box-mangle 8ft. 6in. by 3ft. 3in., with patent self-acting risers and gear and friction rollers; one rinsing and wringing machine, with sliding drainer over trough. The above would comprise all the *machines* necessary.

The *fittings* would include one galvanised iron vessel and wood frame, fitted boiling apparatus with steam supply and cold water; a range or ranges with 30 washing troughs, each 2ft. 6in. by 2ft. by 1ft. 6in., all made in best manner, with copper bolts, nuts and washers; 1½in. pine draining boards and racks to each; full way brass plugs, grates, washers and chains, hot and cold supply copper steam sparge pipe and valves, and strong wood supports and grids.

One range of drying-horses (in a brick-built chamber) with runners, guides, and including the steam coil and necessary heating apparatus.

There should be provided about five 10ft. drying-horses to every 100 patients; therefore in this case for 800 patients there would be not less than 40 of these, and a considerable area would be necessary, having in view the necessity for ample means of drawing out the horses, passageway, &c.

There would also be a laundry stove for heating about 50 irons.

In the Officers' Laundry, an area would be provided sufficient for the working of the following apparatus:—One 26in. hydro-extractor; one patent box-mangle, 7ft. by 3ft., with automatic rising gear and friction rollers, and hard wood bottom; one patent rinsing and wringing machine with drainer and trough; one goffering machine, and one hot calender or cylinder mangle.

The fittings would comprise a boiling vessel with cold water supply only and a steam (copper) coil complete; a range of 12 washing troughs (as for general laundry); one range of drying-horses (about seven 10ft. horses), and one laundry stove for about 20 irons.

In the Foul Linen Laundry, space should be found for one hydro-extractor, one mangle, 7ft. by 3ft., and one rinsing and wringing machine.

The fittings here would include one boiling vessel, with cold-water service, and steam (copper) coil; one range of seven washing troughs; one foul linen tank (provision to be made for drainage and overflow to drains); and one range of seven 10ft. drying-horses.

In an asylum for 800 patients, the total number of inmates (patients and officials) may be taken, approximately, at about 1,000 persons, and in an estimate before me by Messrs. D. W. Forbes and Co., Limited, the total cost of the laundry appliances for an asylum of this size, including hot, cold, and waste services for the laundry, should not exceed £1,600; the figures being divided thus:—General laundry, £1,040; officers' laundry, £370; foul washhouse, £190.

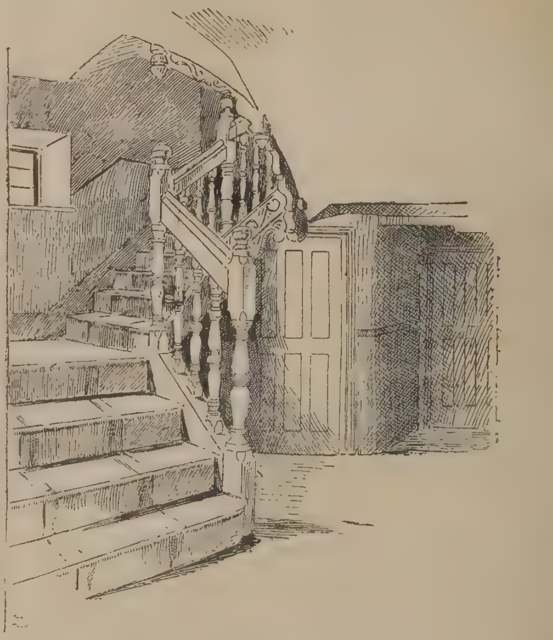
In Fig. 37 the boilers (six in number) would be used for all purposes connected with the engines, hot water and steam supply, electric lighting, &c., as well as for laundry purposes, and arrangements should be made for such utilisation of exhaust steam from the engines as may be found advisable.

The laundries of all asylums should be arranged of sufficient capacity to provide the whole of the inmates with at least two changes of underclothing every week, and with a sufficient further provision for the cleansing of bed-linen, table linen, and the preliminary cleansings of the bedclothes and linen of patients with foul and dirty habits. Therefore, before planning an asylum laundry, full information is required by the architect as to the numbers of the clean and dirty classes of patients; these differ in proportion in various institutions; but frequently I believe the foul laundry would not be constructed on too large a scale if arranged for about *one quarter* of the total number of patients; and in connection with this department there should be a disinfecting apparatus, in such a position as is indicated on Fig. 37 (in the receiving-room at H). The advantage of this arrangement is that the persons bringing the foul clothing pass it into the disinfecting apparatus, whence it is taken into the washhouse.

(*To be continued.*)

THE ARCHITECTURAL ASSOCIATION EXCURSION, 1895.

THE excursion programme has now been settled upon, and the district round Cheltenham will furnish some Gloucestershire houses of architectural interest, and some degree of freshness will be imparted to the proceedings by a steam-launch trip up the Avon in the Pershore country, starting from Tewkesbury. The excursion will thus encroach to some extent upon the places visited during the Worcester excursion, when Mr. Aston Webb was president, and it nearly reaches the neighbourhood comprised by the Warwick programme, when the late Bowes Paice presided, and the late Charles Pink acted as secretary. Cirencester, with its grand church and great porch, is too far across country to be reached from Cheltenham, and difficulty of access will exclude Northleach and Stowell, where Earl Eldon has a new house of some consequence. On Monday, August 12, going northwards from the headquarters at Cheltenham, the excursionists, under the guidance of Mr. W. D. Caröe, the new president, will visit Southam House, with its farm-buildings and pigeon-house, &c., and Bishops Cleeve, with its church and old houses, will make out the day. On Tuesday, Tewkesbury Abbey, old bridge, and timbered houses in the streets will be seen, with the river trip to follow. Wednesday is to be devoted to Chastleton, on the borders of Oxfordshire (see "B. N.," May 12, 1893, for view). On Thursday, Broadway, interesting by reason of the old houses and church, Staunton, Stanway, and Brickland will be visited. Friday is to be occupied at Severnhampton, Winchcomb, and Sudeley Court. On Saturday the Associationists will take the city and cathedral at Gloucester on their way home.



STAIRCASE, RODWAY MANOR.

SOME ANCIENT ENGLISH HOMES.*

THE attractive title adopted by Elizabeth Hodges for her carefully-compiled and readable record, just published, about a few comparatively unknown houses in Warwickshire and Gloucestershire, is well chosen to insure an inquiry into its contents, for the growing interest in all that pertains to our national historic homes every year increases. In the search, however, for fresh material adapted to illustration and description from an architectural and archæological point of view, it necessarily becomes more and more difficult to discover examples which have not hitherto been sketched and published in a more or less complete form. The days for the continued reprinting of old, worn-out stereotyped wood-blocks, which at best but crudely depict objects of topographical interest, are, fortunately, passing away; and excursionists now are, rightly enough, not satisfied with the miserably produced guide-books which formerly obtained a market in the absence of any serious competition. Education has materially improved the general knowledge of the public in such matters, and most people who possess any taste at all desire to obtain better drawings and more accurately-written descriptions of the places they visit in these times of cheap trips and easy locomotion. The houses selected for record in this volume, which Mr. Fisher Unwin has added to the books of the season, are still practically but little known, and their importance is not likely to bring either of them into marked prominence.

Such ancient dwellings, nevertheless, are eminently typical, and while affording glimpses of the family and social life of bygone times, they serve to furnish associations and enrich the pages of our local history. The first two old homes described in the volume under notice are Lisle House, at Wotton-under-Edge, and Bradley Court. The gabled roofs of the first of these "standing houses" group with the church tower at Wotton, but only fragments remain of the once princely mansion of the Berkeleys. The ball-crowned gate entrance still stands, and the general outline of the site can be distinguished within the rampart wall, on which a picturesque summer-house remains as an original feature. Half a mile west of Wotton stands the small hamlet of Bradley. No record of the present house known as Bradley Court is known to exist, but it presumably dates from the early days of James I. The sturdily-proportioned bay-like projections which run up the whole height of the building break the sky-line pleasantly, and mingle suggestively with the gables of the roofs. There is, however, but little detail of an ornamental kind, and the drawing which we print herewith furnishes a capital idea of the house. The trim parterres of the 18th century, the stone-built summer-house and dovecote, the charming gardens which surround "the Court," and the two fine avenues of elms which lead up to it, charmingly augment the quaintness of the homestead. Beverston Castle is next described, and then Rodway Manor, Mangotsfield, some five miles to the north-east of Bristol. The house, which is three stories high, has been too well "done up and excellently kept" to bear distinctive marks to denote its age. Inside the buildings the signs of historic construction are more conspicuous. The first object which meets the eye on entering is a good specimen of the Jacobean dog-legged stairway winding

---

* Some Ancient English Homes and their Associations, Personal, Archæological, and Historic. By Elizabeth Hodges. Illustrated by S. J. Loxton. London: T. Fisher Unwin. 1895.

MANOR HOUSE, LITTLE SODBURY.

up to the top story with its carved strings and shaped verges, massive newels and turned balusters, black and polished with age. The sketch with which we are enabled, by the publisher's courtesy, to illustrate these notes gives a very good notion of its design. Tradition has endeavoured to associate this old place with three of the Queens of Henry VIII.—viz.: Anne Boleyne, Jane Seymour, and Catherine Parr—though why it would be difficult to tell. The windows show its Tudor origin, but the house could never, even its palmiest days, have accommodated a royal party, and never could have ranked with the neighbouring mansions of Thornbury and Yate. Yate Court, long since demolished by the Parliamentarians at the time of the civil war, was not rebuilt, but a portion of Lord Maurice's mansion is incorporated in the present farmhouse standing on the west side of the courtyard. The authoress next describes Caludon Castle, near Coventry, where the remains of the banqueting-hall form the most interesting part of the existing ruin. Kingsbury, eleven miles from Birmingham, and Hurley Hall, the home of the Willingtons, are next recorded. Following these is a history of Little Sodbury Manor, which lies in a small village on the western slope of the Cotswolds, four miles from Yate. It is built upon a terrace cut along the side of the hill, and has a pleasant south-west aspect. The centre of the mansion is occupied by the usual lofty hall, still entire, but dismantled, with its wind-braced roof supported on angel corbels, its music gallery and screen at the south end. A grotesque mask carved in stone is pointed out in the wall opposite the western door, as the squint, formed by the monster's mouth, through which the ladies could obtain a view from their gallery outside the hall upon the revelry going on at times within its walls. Many additions of the last century considerably mar the artistic effect of the older portions, but the accompanying view, lent us by Mr. Unwin, shows what a quaint specimen of Mediæval Domestic architecture can be seen at Little Sodbury. Horton Court and Bidford Grange (which questionable tradition states is the original of the "dejected Mariana's" "Moated Grange" in "Measure for Measure") follow, and conclude the volume. The book is handled in a popularly entertaining manner, and makes a connecting narrative from the materials brought together, and if its architectural character at times is slight, it is but fair to remark that the aim of the volume was not intended to be more than an antiquarian record for the general reader. Without attempting to furnish a textbook for the historian, the architect, or the archæologist, the writer and the artist who combined forces to produce this record have so far succeeded as to well merit the attention of all three authorities.

BRADLEY COURT.

* * *

At a meeting of subscribers to the infirmary at Rochdale, held on Wednesday week, it was decided to carry out extensions to the building at an estimated cost of about £5,000.

SHERATON'S CABINET-MAKER AND DRAWING-BOOK.

VERY few complete and perfect copies of the rare and valuable third edition of Sheraton's famous book are now to be had, and high prices are obtained whenever a clean impression comes into the market. Messrs. Gibbings and Co., of Bury-street, in conjunction with Mr. Batsford, as we understand, have therefore done well in their reissue of the work in facsimile, so that now cabinet-makers and designers, as well as technical teachers, can obtain for £2 10s. an entire reproduction of Sheraton's volume, which, for all practical purposes, is as good as the original. Mr. Wasmuth, of Berlin, a few years ago reproduced Chippendale's great folio, and English enterprise, following this lead, has risen to the occasion, and students in art may now secure Sheraton's companion volume, which cannot fail to be welcomed by many who, in a variety of ways, are associated with the production of furniture and the technical art of upholstery. It is hardly necessary for us to attempt anything like a review of the book itself. To name it surely should suffice as a guarantee of its interest and quaintness. The preliminary part of the volume is devoted to a series of problems intended to provide the student and craftsman with instruction in the matter of perspective delineation as applied to furniture design, besides a variety of diagrams of a practical kind, such as the method recommended by the author for planning carpets, mitring mouldings, and setting out elliptic domes. The Classic orders of architecture are described with typical illustrations, and rules are given, too, for tinting drawings. More modern books have developed and concentrated, of course, most of the principles so enthusiastically put forward a hundred years ago by Sheraton for the advantage of his pupils; but although some of his methods may be considered antiquated nowadays, no expert, however efficient, would fail to recognise the author's useful rules, and no student can afford to overlook the principles which underlie this master's unreserved and, perhaps, sometimes verbose descriptions. Few men of taste have exercised so lasting an influence as Sheraton, and his designs, after more than a century has elapsed, are more valued still for their grace of form, elegance of detail, and lightness of perfect construction than the productions of any other maker. The plates include his "Universal Table," a sideboard with pot-cupboards at the ends, useful patterns for bookcase doors, secretaries, and library tables, "Kidney tables," and cylinder desks, sofa-beds, alcove-beds, a summer bed in two compartments (invented by the groom of the household furniture to the Duke of York), and "an elliptic bed for a single lady." Chairs are given, of course, in great variety, with dressing-tables, washstands, clocks, and fire-screens. In the "Accompaniment," details are added of carved work, Girandoles, painted panels, table centres, pilasters, and window-cornices, making together a thick book of some 440 pages, including no less than 122 plates. We have said enough to draw attention to this standard volume thus so capitally reproduced, whereby, instead of having to wait the chance of securing some imperfect, soiled, or mutilated copy of the original, the reader may at once obtain the new edition at about a fifth of the cost demanded for the old impressions.

NOTES ON BUILDING PRICES.

By JOHN LEANING.

(*Continued from p.* 581, *last Vol.*)

TEAK.

THE use of teak in buildings has within a few years much increased, and for many purposes it is a valuable wood. No timber bears the weather better; it is consequently frequently used for the exposed fittings of ships, such as decks, seats, gratings to hatchways, &c. Vast quantities have, of late years, been used as backing for the armour-plating of war ships, and this demand has increased the price. The lessons taught by the recent Naval War between China and Japan will probably induce a greater use of iron instead of wood, and the demand for naval purposes will decrease.

For sills of sash-frames, for dormer fronts where the wood is to remain uncovered, for hospital floors, and for good internal fittings, it cannot be surpassed.

Malabar produced the best teak, but it is now seldom seen in European markets. The chief supply is drawn from Burmah or Siam, and is shipped from Rangoon, Moulmein, and Bangkok.

It is imported in squared logs from 15ft. to 40ft. in length, and from 12in. to 27in. square; also in planks of various widths and thicknesses.

The so-called African teak is not teak, and is an inferior wood of poor quality. Teak, whether log or plank, is sold at the timber sales at per load of 50c.ft.

The labour on teak is equal to that on Honduras mahogany (which see). The waste may be taken as about 5 per cent. more than deal—*i.e.*, 7½ per cent. for sawing and 7½ per cent. for conversion = 15 per cent. in all.

The price of good teak is quoted by the retail timber merchant by the inch in thickness; the other thicknesses above inch increasing in uniform proportion. The rates are as follows:—

½in.	⅝in.	¾in.	1in.	1¼in.	1½in.	1¾in.	2in.
-/5¾	-/6¾	-/7¾	-/9	-/11¼	1/1½	1/3¾	1/6

Add 7½ per cent. for conversion:—

-/0⅜	-/0½	-/0⅝	-/0⅝	-/0⅞	-/1	-/1⅛	-/1⅜
-/6⅛	-/7¼	-/8⅜	-/9⅝	1/0⅛	1/2½	1/4⅞	1/7⅜

Adopting for the purpose of illustration and comparison the same items as before, we have for the deal skirting in two pieces, material 2¾d., labour 6⅝d. = 9⅜d. total. Excluding the deal fillet and its fixing, we have 8½d. remainder. If we increase the labour constants for deal by 100 per cent., and adopt the teak prices in the table of teak, the calculation will be as follows:—

ft.	in.		s.	d.
1	0	run of 1in. by 4½in. teak, at 9⅝d.	0	3⅝
1	0	,, of 1¼in. by 7in. teak, at 12⅛d.	0	7⅛
1	0	,, labour to moulding 3in. girth, at ·144 super. of 7s. 11d.	0	3½
1	0	,, labour to moulding 1in. girth, at ·024 of 7s. 11d.	0	2¼
1	4	super. of planing, at ·020 of 7s. 11d. ..	0	2½
1	0	run fixing ·030 of 7s. 11d.	0	2⅞
1	0	,, rebated edge to 1¼in., ·006 of 7s. 11d.	0	0⅝
1	0	,, rebated edge to 1in., ·006 of 7s. 11d.	0	0⅝
			1	11⅛
		Add 10 per cent. for extra care and protection	0	2⅜
		Cost per foot run	2	1½

Three times 8½d. is 2s. 1½d.

Applying the same process to the calculation of the value of 1¼in. square framed doors, we find the material valued at 2¾d., the labour 4¾d., equal 7½d. total. If we increase the labour constants for deal by 100 per cent., and adopt the teak prices in the table of teak, the calculation will be as follows:—

					s.	d.
2/3	0					
	9	4	6			
23	2					
	4½	8	8			
		13	2	1¼in. teak at 12⅛d.	13	3⅝
2/1	1					
1	8	3	7			
2/1	1					
3	9	8	2			
		11	9	¾in. teak at 8⅜d.	8	2⅜
Glue					0	3½
Glass-paper					0	1½
					21)21	11
Cost of material per foot super.					1	0½
Labour making ·084 of 7s. 11d.					0	8
Labour fitting and hanging ·016 of 7s. 11d. ..					0	1½
					1	10
Add 10 per cent. for extra care and protection					0	2¼
Cost per foot super.					2	0¼

Three and a quarter times 7½d. equal 2s. 0¾d.

AMERICAN WALNUT.

American walnut work is of equal value to wainscot, both as to labour and materials. The labour on some is exceptionally troublesome, but as a general rule wainscot is a fair parallel. Its use for internal fittings is increasing. It is imported in log planks and boards of various thicknesses. The leading brand is <K>. The greater part is shipped from Baltimore or Quebec.

AMERICAN WHITE WOOD.

American white wood or Canary white wood is shipped from Baltimore or New York in logs, planks, and boards. The better qualities are very fine grained and of good figure. It takes polish well. It is frequently used for shop fittings, and when stained and French-polished, bears a fair resemblance to mahogany. The labour is not more expensive, nor the waste greater, than on deal. The timber merchants' prices are quoted by the inch in thickness, the prices for the other thicknesses above inch increasing in uniform proportion.

½in.	¾in.	1in.	1¼in.	1½in.	1¾in.	2in.
-/2	-/3	-/3½	-/4⅜	-/5¼	- 6⅛	-/7

Add 5 per cent. for conversion:—

-/0⅛	-/0⅛	-/0⅛	-/0¼	-/0¼	-/0⅜	-/0⅜
-/2⅛	-/3⅛	-/3⅝	-/4⅝	-/5½	-/6½	-/7⅜

Adopting, for the purpose of illustration and comparison, the same items as before, we have for the deal skirting in two pieces, material 2¾d., labour 6⅝d. = 9⅜d. total. Excluding the deal fillet and its fixing, we have 8½d. remainder. Adopting the labour constants as on deal, and adding 10 per cent. for extra care and protection, the calculation will be as follows:—

ft.	in.		s.	d.
1	0	run of 1in. by 4½in. white wood at 3⅝d. per foot supl.	0	1⅜
1	0	,, of 1¼in. by 7in. white wood at 4⅝d. per foot supl.	0	2⅝
1	0	,, labour to moulding 3in. girth at ·072 supl. of 7s. 11d.	0	1¾
1	0	,, labour to moulding 1in. girth at ·012 of 7s. 11d.	0	1⅛
1	4	supl. planing at ·010 of 7s. 11d.	0	1¼
1	0	run fixing at ·015 of 7s. 11d.	0	1½
1	0	,, rebated edge to 1¼in., at ·003 of 7s. 11d.	0	0¼
1	0	,, rebated edge to 1in. at ·003 of 7s. 11d.	0	0¼
			0	10⅛
		Add 10 p.c. for extra care and protection ..	0	1
		Cost per foot run	0	11⅛

One and one-third times 8½d. is 11⅓d.

Applying the same process to the calculation of the value of 1¼in. square-framed doors. We find the material valued at 2¾d., the labour 4¾d. = 7½d. total. Adopting the deal constants for labour, the calculation will be as follows:—

					s.	d.
2/3	0					
	9	4	6			
23	2					
	4½	8	8			
		13	2	1¼in. white wood at 4⅝d.	5	1
2/1	1					
1	8	3	7			
2/1	1					
3	9	8	2			
		11	9	¾in. white wood at 3⅛d.	3	0¾
Glue					0	3½
Glass-paper					0	1½
					21)8	6¾
Cost of material per foot supl.					0	4⅞
Labour making ·042 of 7s. 11d.					0	4
Labour fitting and hanging ·008 of 7s. 11d. ..					0	0¾
					0	9⅝
Add 10 p.c. for extra care and protection ..					0	1
Cost per foot super.					0	10⅝

One and one-third times 7½d. is 10d.

SEQUOIA.

Sequoia, known also as Californian red wood, is imported generally in planks of various thicknesses, 2in. and upward, and sometimes as wide as 3ft. 6in. The shipping port is San Francisco. Some of this wood has a pleasing figure; it is used for internal fittings, French polished. The labour and waste is about equal to that on deal.

The timber merchants' prices are quoted by the inch in thickness, the prices for the other thicknesses above inch increasing in uniform proportion—

½in.	¾in.	1in.	1¼in.	1½in.	1¾in.	2in.
-/2¼	-/3¼	-/4	-/5	-/6	-/7	-/8

Add 5 per cent. for conversion—

-/0⅛	-/0⅛	-/0⅛	-/0¼	-/0¼	-/0⅜	-/0⅜
-/2⅜	-/3⅜	-/4⅛	-/5¼	-/6¼	-/7⅜	-/8⅜

Adopting for the purpose of illustration and comparison the same items as before, we have for the deal skirting in two pieces, material 2¾d., labour 6⅝d. = 9⅜d. total. Excluding the deal fillet and its fixing, we have 8½d. remainder.

Adopting the labour constants as in deal, and adding 10 per cent. for extra care and protection, the calculation will be as follows :—

ft.	in.		s.	d.
1	0	run of 1in. by 4⅛in. red wood, at 4⅛d. per foot super.	0	1½
1	0	,, 1¼in. by 7in. red wood at 5¼d. per foot super.	0	3
1	0	,, labour to moulding, 3in. girth, at ·072 super. of 7s. 11d.	0	1¾
1	0	,, labour to moulding, 1in. girth, at ·012 of 7s. 11d.	0	1⅛
1	4	super. planing at ·010 of 7s. 11d.	0	1¼
1	0	run fixing, at ·015 of 7s. 11d.	0	1½
1	0	,, rebated edge to 1¼in., ·003 of 7s. 11d.	0	0¼
1	0	,, ,, ,, to 1in. ,, ,, ..	0	0¼
			0	10⅝
		Add 10 per cent. for extra care and protection	0	1
		Cost per foot run	0	11⅝

One and one-third times 8½d. is 11¼d.

Applying the same process to the calculation of the value of 1¼in. square framed doors, we find the material valued at 2¾d., the labour 4¾d. = 7½d. total. Adopting the deal constants for labour, the calculation will be as follows :—

						s.	d.
2/3		0					
		9	4	6			
	23	2					
		4½	8	8			
			13	2	of 1¼in. red wood at 5¼d...	5	9⅛
2/	1	1					
	1	8	3	7			
2/	1	1					
	3	9	8	2			
			11	9	¾in. red wood at 3⅜d.	3	3⅝
Glue						0	3½
Glass-paper						0	1½
						21)9	5¾
Cost of material per foot super.						0	5⅜
Labour making ·042 at 7s. 11d.						0	4
Labour fitting and hanging ·008 at 7s. 11d...						0	0¾
						0	10⅛
Add 10 per cent. for extra care and protection						0	1
Cost per foot super.						0	11⅛

One and a-half times 7½d. is 11¼d.

ELM.

Elm is very rarely used for building work. Occasionally it is seen in stables as wall-lining or boarding to stall divisions. It has no particular merit to recommend it for such purposes. In water it is said to be exceptionally durable.

The labour and waste is equal to that on wainscot. It can be bought of country timber merchants, in sawn planks or scantlings, at the rate of 2s. 6d. per foot cube. In fair quantities the various thicknesses could be obtained at similar proportional rates. Coffin plank, which is usually of fair quality, is quoted by the timber merchants at per 100ft. of inch, commonly about 17s. in the summer, and about 18s. in the winter—*i.e.*, 2d. and 2¼d. per inch ; 2s. 6d. per foot cube is equal to 2½d. per inch. If this price be uniformly adopted, the difference will be sufficient to cover any extra sawing, and the prices for various thicknesses would be as follows :—

¾in.	1in.	1¼in.	1½in.	1¾in.	2in.	2½in.	2¾in.	3in.
-/1⅞	-/2½	-/3⅛	-/3¾	-/4⅜	-/5	-/6¼	-/6⅞	-/7½

The comparison of labour and materials may be investigated in the same manner as recommended for the other kinds of wood.

IRONMONGERY.

Builders' ironmongery varies very much in quality, and consequently in price. Those manufacturers who have a high reputation for their wares—such as, among others, Chubb, Hobbs, and Tucker and Reeves, of London, and Gibbons, of Wolverhampton, for locks ; Baldwin, of Birmingham, for butts, &c.—are able to command high prices ; but much of the ironmongery in use is of very poor quality and low priced, and in the case of brasswork the weight of the articles is reduced to the lowest possible limit. If bought by retail, as it often is in the case of small jobbing work, the price is high ; for the profits of a retail ironmonger, selling (as he does) articles in small quantities, must. of necessity, bear a large proportion to the original cost.

The builder who has a large business buys his ironmongery in large quantities of the wholesale manufacturer, or he opens an account on special terms with a local ironmonger, who reduces his prices in consideration of the quantity required.

The trade lists of the large houses which deal in builders' ironmongery—such, for instance, as Tonks, of Birmingham, or Pfiel Stedall, of London—are indispensable to the estimator, and the various trade discounts on the various kinds must be known.

Articles of ironmongery are frequently inadequately described in specifications ; butts, of which there are a great variety, being frequently described by their length only. All kinds of ironmongery are conveniently designated by numbers from a trade list.

Knowing the net prices of the articles, the only other considerations will be fixing and screws, and profit.

A few constants for fixing to deal are given below, and will serve as a guide for *similar* articles not mentioned therein. The fixing of butts is properly a part of the hanging of a door ; but, although this view is correct, the prices in most bills of quantities will be found to include something for fixing.

It is a common practice with estimators to charge a certain number of pence per inch for bolts and fixing and profit—as 2d. for iron bolts, 3d. for brass, 2s. for the fixing of a mortise lock, &c. Some such ready rules will be found convenient.

For fixing ironmongery to hardwoods, add 25 per cent.

Prices of rim locks generally include the furniture ; for mortise locks they do not.

Turnbuckles	·033	0	0
Button and plate	·022	0	0½
Cabin hooks 6in. to 9in.	·033	0	1

Relacquering.—Satisfactory repainting of good work requires the removal and refixing of the whole of the ironmongery except hinges and locks ; but the lock furniture would be removed also. Often, in such a case, the brass lock furniture and the general brasswork would be relacquered. Relacquering should be done with judgment, as it is not an uncommon thing to relacquer brasswork at a cost beyond the value of new articles of a similar kind.

Relacquering involves, besides the lacquerer's charge, taking off, labelling, conveying to and from the lacquerer's, and refixing.

As a rule, the value of taking off is about two-thirds of the value of original fixing.

The following list gives the prices commonly charged to builders by the wholesale people for relacquering. They will serve as a guide for the pricing of similar articles not mentioned therein :

	s.	d.
Butts up to 4in., per pair	0	3

Brass barrel bolts, per inch	0	0¾
Sash fasteners	0	2½
Casement fasteners	0	3
Sash lifts	0	1½
Letter plates	0	6
Bell levers	0	4

ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.

THE annual meeting of this association was held in the Town Hall, Halifax, on Thursday in last week. Mr. Edward Rice Sweet Escott, borough engineer, Halifax, the president, occupied the chair. On the opening day a vote of thanks was accorded to the retiring president, Mr. A. M. Fowler, of Manchester. Mr. C. Jones, of Ealing, hon. general secretary, in submitting the annual report, said the association had entered upon its 21st year. During the past year satisfactory progress had been made. In the financial year ending April 30 last 73 new members—56 ordinary members, and 17 graduates—had joined their ranks, 7 members had resigned, 14 names had been written off, and 5 members had died. At the close of the year the numbers on the roll were 9 hon. members, 570 ordinary members, and 67 graduates, making a total of 646, or an addition of 47 to the numbers of the preceding year. Three graduates had been transferred to the list of members. The statement of accounts showed a balance in hand on April 30 of £235 14s. 4d., and invested capital amounting to £300. The new council had for its president Mr. E. R. S. Escott, and as vice-presidents Mr. A. R. Binnie, Mr. C. H. Lowe, and Mr. O. C. Robson. The report was adopted on the motion of Mr. C. H. Lowe, Hampstead, seconded by Mr. Mann, Sevenoaks. The President, in the course of his address, said that perhaps no subject of late years had called for more consideration than that of sewage disposal. Throughout the country Rivers Conservancy Boards were being established with powers equal to the provisions of the Public Health Act, 1875, and local authorities would no longer be allowed to discharge the raw sewage of their respective districts into any stream flowing through the same. Acts of Parliament had for years given corporations and local boards all the powers necessary to deal with this important subject, yet the progress made in manufacturing towns had not been as great as many of them had anticipated. Hence the municipal engineer should persevere in this difficult yet interesting branch of his profession, until the streams of every district were flowing with clear and pure water from source to ocean. He would not lay down any hard-and-fast line in favour of any definite system of sewage disposal. It was well to remember that a system in every way adequate for a suburban district might in no way answer the requirements of a large manufacturing town. They were all agreed that a clear and bright effluent could be produced by land filtration where there was sufficient area ; yet an effluent could be produced by chemical treatment and precipitating tanks of such a standard of purity as to justify its discharge into any river or stream. The extent of land required was to be determined by circumstances. One acre, or even half an acre, per 1,000 of the population must in many cases be quite out of the question. In the near future, with scientific development, the land required would be reduced to a small area. A town with 100,000 inhabitants would not require one-twentieth part of an acre per 1,000 inhabitants. Engineers were left very much to their own resources with reference to standards of purity. The effluent that would give satisfaction to the Rivers Conservancy Board was still unknown to them. It was to be hoped that the law relating to combined drainage would be altered, or that the mode of reading the section bearing on the subject would be amended. They must all regret the little progress made by the Amendment Bill in the present session of Parliament. The measure had been systematically blocked on every occasion. Turning to the subject of hospitals and their erection, Mr. Escott remarked that when the cost of a new hospital was defrayed out of rates there was little difficulty to contend with, and no time was lost in executing the works. But when the intended erection comprised an administrative block, and application had to be made to the Local Government Board for sanction to borrow money, the question became one of importance. The cost of a new hospital did not appear to enter into the consideration of the head department, and when the latter was waited upon with some modest design, of an inexpensive character, in every way suitable to meet the pressing requirements of the epidemic, the promoters were most politely handed a carefully drawn up report upon the provisions of isolation and hospital accommodation for local sanitary authorities, accompanied by several specimen sheets of plans and sections, showing administrative blocks and wards, drawn to suit the requirements of nearly every district. These were accompanied by the intimation that plans drawn to correspond with these specimens were the only plans the Department would consider or accept. It was, therefore, necessary to produce another set of drawings before sanction to borrow was given. Such delay might lead to serious consequences if an epidemic was raging at the time. To avoid unnecessary delay, it was better for engineers to approach the officials of the Local Government Board in the first instance. The plans on the walls of the room in which they were assembled complied with the requirements of the Local Government Board for a smallpox hospital for Halifax. A site of 65 acres, two miles from the Town-hall, upon high ground, had been secured, and the works could be proceeded with as soon as the health department of the corporation thought necessary. The approximate cost would be £12,000, exclusive of the land.

Papers on the sewage works at Royton, near Oldham, were read by Mr. T. S. McCallum, of Manchester, and Mr. W. Naylor, one of the inspectors of the Irwell and Mersey Conservancy Board. That by Mr. McCallum dealt chiefly with the construction of the refuse destructor and sewage purification works at Royton, and Mr. Naylor described the tests applied to the machinery, the refuse destructors, and the effluent.

Subsequently the members were taken to see the new Technical School, which is in course of erection, the People's Park, and the Free Library. In the evening they dined together at Bankfield Mansion.

CLASSIC DETAILS AND THEIR APPLICATION.*

By G. A. T. MIDDLETON.

II.—CLASSIC TIMES: THE IONIC ORDER.

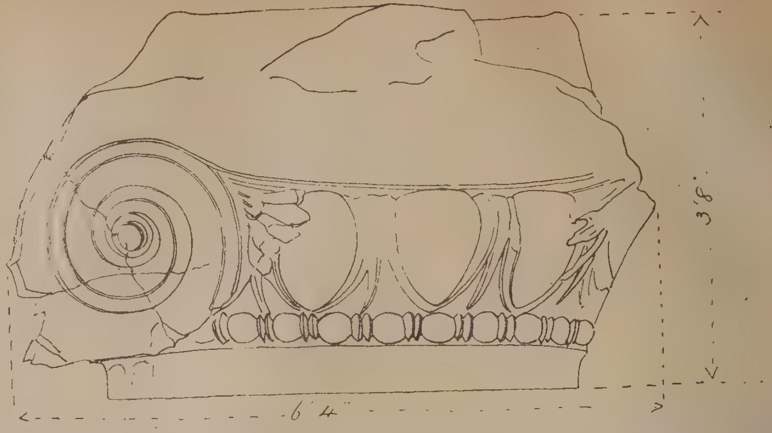
THE origin of the Ionic Order is even more deeply involved in mystery than is that of the Doric, for there is no Proto-Ionic example known which compares in the least with the Proto-Doric of Beni-Hassan. A few small indications point to its introduction from Assyria and Persia rather than from Egypt, and the use of a base, together with the form of the flutes, as if gouged out with a gouge, suggest its being the translation into stone of forms originally devised for timber. Again, therefore, we must accept it upon its first appearance in Grecian work as a complete and fully developed order, varying in its different examples as did the Doric, but having in all cases an entirely different part to play. When used alone it was employed in all instances save one upon buildings of smaller size than was the Doric—upon the lighter edifices where grace and elegance were to be aimed at, rather than majesty and the over-awing of the multitude. The one exception is the Temple of Diana at Ephesus, where queenly rather than kingly dignity was achieved, and this, too, was built at a somewhat later date than were the greater Doric works.

Under these circumstances an increased employment of enrichments was to be expected, and such we find; but the parts were still so few that it was upon their co-relation that the effect principally depended, and enrichments had to be introduced with the utmost skill and care, else the whole would have been spoilt.

Similarly the proportions became more slender. The following table, taken from Gwilt, gives those of the now-destroyed Temple on the Illyssus, and of the two Ionic porticoes of the Erechtheium.

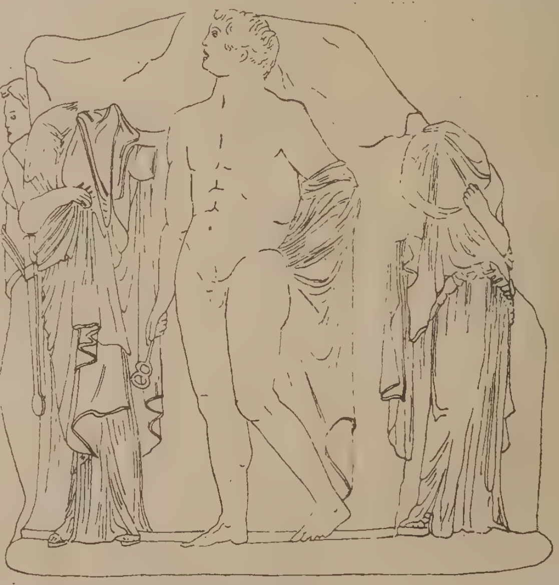
—	Diameters High.	Height of Entablature to Diam.	Inter-Columniation.	Height of Capital in Terms of Diam	Upper Diam. in Terms of Lower Diam.
Illyssus	8·241	2·265	2·090	·610	·850
Minerva Polias	9·119	2·287	3·500	·700	·833
Erechtheus	9·337	—	2·000	·773	·816

With these we may compare the proportions of the Temple of Diana at Ephesus, the columns of which were 8·5 diameters high, while the taper was so great that the upper diameter was only ·786 of the lower—and this in spite of the columns being of no extreme slenderness. It will thus be seen, that when greater dignity was called for, greater strength was shown in the proportions, the great size of the columns, again, carrying off a degree of taper which would have appeared clumsy in a small building.



FRAGMENT OF AN IONIC CAPITAL FROM THE TEMPLE OF DIANA AT EPHESUS.
(Now in the British Museum.)

With regard to the several parts of the order, a considerable amount of freedom was evinced. The bases alone varied from the simple roll at the foot of the sculptured columns at Ephesus to the elaborately-moulded base, in two stones, of the unsculptured columns in the same building; but the upper member is almost invariably a roll, either plain, or fluted horizontally. The columns also, though generally fluted with 20 tolerably deep flutes separated by fillets, were, in rare instances, as at Ephesus, enriched with bands of sculpture, or even, as in the Caryatid Portico of the Erechtheium (by the way, rather an altar than a portico) replaced by sculptured figures. In this way it will be observed that sculpture was used in this order, not merely as an adjunct to, but as an integral part of, the architecture.



FRAGMENT OF THE LOWEST DRUM OF A COLUMN FROM THE TEMPLE OF DIANA AT EPHESUS.
(Now in the British Museum.)

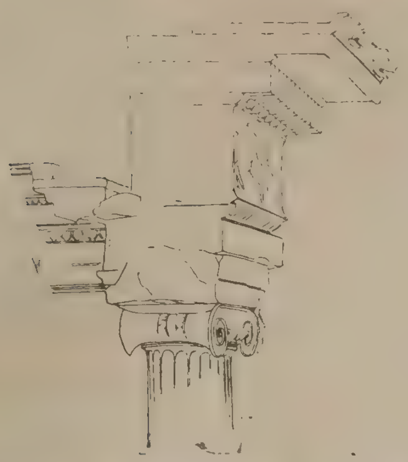
Though the voluted capital is considered to be typical of the order, it not only occurs in many forms, but is not even invariable, as it will be observed that the caryatidæ already mentioned are crowned in a much more simple manner; and there are large square capitals in the British Museum from the Temple of Athené Polias at Priene, which are carved with winged griffins of Assyrian type, and in which the volutes are quite minor features. The general type, however, is that illustrated, from Ephesus, and from the Mausoleum, though the scale is generally smaller; and occasionally there are two, and even three, rolls to the volute, as in the famous example of the Erechtheium, which also has a band of the anthemion ornament round the top of the shaft. As an example of how far the refinement of mouldings was carried, it may be noticed that the fillet to the volute roll at Ephesus is not flat, but slightly convex, though it becomes flat, and is more coarsely worked, when it is converted into a band above the eggs, and consequently would be hidden from sight.

The entablature, like the other portions of the Ionic Order, was treated with considerable freedom by the Greeks, the proportions especially being liable to alteration, though the general arrangement of an architrave in three facets, then a sculptured frieze, and then the cornice over, was almost invariable. The example illustrated herewith, from the Mausoleum at Halicarnassus, may well be compared with others. The moulded band separating architrave from frieze is here formed of the egg and tongue; while at Eleusis it is a plain moulding of cyma reversa below and cavetto above it, and upon the Erechtheium there is the leaf-and-dart enrichment, with bead and fillet below and a moulding over. Then the frieze, though sculptured generally, is sometimes plain, and the cornice varies greatly. The large dentils at Halicarnassus, with egg and tongue under and cyma reversa above, are of smaller proportion at Eleusis, with cyma above and below, and this is almost the same in the Caryatid Portico at the Erechtheium, save that there the cymas are enriched with leaf and tongue; while the dentils are absent from the rest of the Erechtheium, a single leaf-and-tongue enriched cyma alone remaining as bed-mould to the cornice.

In the cornice itself, the corona seems to be invariable, and also the cyma recta used as a crowning member, and worked as a gutter behind, with outlets for the water provided through lions' heads at frequent intervals; but the small moulding between corona and cyma is open to variation, and the cyma itself is sometimes plain, but more often enriched with the anthemion.

The Ionic Order seems to have been a good deal more used by the Romans than was the Doric, and though generally as an applied ornamental order, it sometimes appears as a constructional order also. Thus it is found treated in different ways, and differently again when, as an applied order, it was used in superimposition to the Doric, and so had to be proportioned to harmonise with the order below, and to have its mouldings, and even its base, contrived for observation entirely from beneath. Still, generally speaking, both its proportions and details compare tolerably closely with those adopted by the Greeks, and Gwilt's table of proportions may again be quoted, as follows:—

—	Diameters High.	Height of Entablature to Diam.	Inter-Columniation.	Height of Capital in Terms of Diam.	Upper Diam. in Terms of Lower Diam.
Fortuna Virilis...........	8·796	2·182	2·125	·457	·874
Theatre of Marcellus...	9·000	2·391	—	·557	·842
Colosseum	8·842	2·280	—	·466	·833



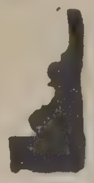
CAPITAL AND ENTABLATURE OF THE MAUSOLEUM AT HALICARNASSUS.

(From the British Museum.)

CARYATID FROM THE S.W. PORTICO OF THE ERECHTHEIUM.

(Now in the British Museum.)

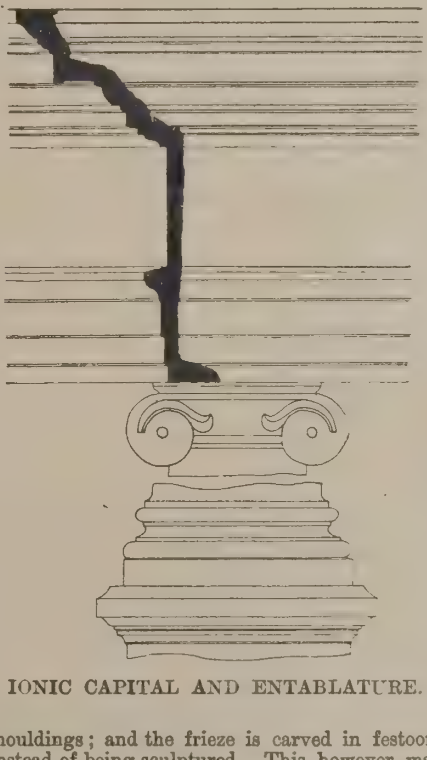
The greatest variation from Grecian practice will be observed to lie in the height of the capital. Of course, there are the usual changes in the contours of the mouldings, but in other respects most of the other details coincide with tolerable exactitude with the Grecian; but the capital is flat both in actuality and in appearance, the waved line across the top being made stiff and straight, and the light elegance of the order is thus much interfered with.



IONIC BASE FROM ELEUSIS.

When employed as a constructional order, it cannot be said that the arrangement of the angle capital is happily managed either by the Greeks or Romans, and certainly no satisfactory expedient has yet been discovered for overcoming this fault, where the order is returned.

In the Temple of Fortuna Virilis the facets of the architrave are separated from one another by mouldings; and the frieze is carved in festoons instead of being sculptured. This, however, may be looked for, figure sculpture being much less used upon Roman than upon Grecian buildings, and being replaced by the work of the stonecarver in a repeating pattern of natural leaves and flowers.



IONIC CAPITAL AND ENTABLATURE.

* * *

FOUNDATIONS IN QUICKSANDS.

THE method of excavating, or taking out so many hundreds or thousands of tons of one description of material, to replace them with an equivalent quantity of another description, in order to obtain foundation for an engineering work of magnitude, is a tedious and laborious operation. Not only does the difficulty augment in the direct ratio of the depth—especially in cases where the piers and abutments, if the work take the form of a bridge, are founded under water—to which the foundations must be sunk, but the cost increases enormously in proportion to the same dimension. One mode of escaping the necessity of taking out stuff and filling in again is probably the oldest employed, and that consists in driving piles into the substratum, which they tend to consolidate, cutting off their heads at the level required, laying a strong timber platform or floor over the whole area, and starting the superstructure upon it. There is nevertheless some amount of excavation and refilling even under these conditions, for it is usual to take out all the loose earth for, at least, 3ft. or 4ft. below ground level, and fill in with solid cement concrete, well rammed and punned, upon which the footing courses are commenced. Simple and undoubtedly useful as this system of getting in foundations is, it has several serious drawbacks. It is, in the first place, slow, whether the ordinary "monkey" be used for driving, or whether steam, air, or gunpowder be the means of obtaining the necessary pressure in the pile engine. The use of timber piles is also very much restricted by the nature of the ground and the number needed.

It may be mentioned that the difficulty of driving the necessary number of piles 30ft. deep into the London clay would of itself have forbidden the construction of timber coffer dams, instead of iron caissons, for the building of the piers of the Tower Bridge. As it was, timber coffer dams were strictly prohibited by the clauses of the Act of Parliament authorising the undertaking.

When piles are got down through sand by the aid of jets of water, a plan adopted for the first time by the late Sir James Brunlees, many years ago, the allegation of slowness does not apply. Piles were also sunk in this manner in the extension of the harbour works at Calais, and, as will be pointed out, the method is susceptible of many and various applications to the getting in of foundations generally. The operation is very simple, and can be described in a few words. A pipe between 2in. and 3in. in diameter is attached to the side of the pile, and connects with a pump. The pile having been pitched, water is forced through the pipe underneath the bottom of the pile, and by loosening the sand until it attains the necessary degree of fluidity, causes the pile to descend with extreme facility and rapidity until the proper depth is reached. When the pile is "down," the feed-pipe can be detached, spiked on to another, and the operation repeated. So great is the accuracy and the certainty of this "washing-out" process, that it is a common practice to make the holes for the bolts in the piles before they are got into position. It is stated that in this manner piles can be got down at the rate of about 10ft. per minute under fair conditions. Those who have had experience in the driving or sinking of piles in foreshores or river beds are aware that it is by no means an uncommon occurrence to come across sunken pieces of wreckage, boulders, and other obstructions, both natural and artificial, which it is absolutely necessary to remove before any further progress can be made. By passing a pipe underneath the obstacle, and turning on the water, it is speedily cleared away, without any knocking of the pile out of position, battering the head to pieces, or breaking it off short, and thus necessitating the always troublesome and unpleasant task of drawing it. After the pile is down, and a reasonable time allowed for the churning up of the sand to subside, it recovers its solidity, and grips the pile so tightly that it becomes well-nigh impossible to "start" it again. It is not difficult to perceive that the system of Sir James Brunlees can be equally well applied, and has been applied to the sinking of caissons and cylinders when circumstances permit of it, which, however, is not very frequently. A large cylinder would require a greater number of jets of water and of pipes, and probably a greater head or pressure of water. But the difference is, after all, only one of degree, and not of principle.

The conditions of the examples to which we have drawn attention become completely inverted, when, instead of it being necessary to impart a certain amount of fluidity, or at least plasticity, to the substratum, the latter possesses it to a degree so excessive as to require artificial agglomeration and consolidation in some form or another. It is, in fact, a case of dealing with a quicksand, a description of foundation which, from time immemorial, has invariably constituted one of the most difficult constructive problems which has ever engaged the attention and taxed the professional skill of those engaged in engineering and architectural works. Several attempts, evincing considerable ingenuity and knowledge as well of the whole subject, have been put forward at different times to effect a satisfactory solution of the question, which it will be interesting and instructive to refer to. One method of dealing with the difficulty was the "Poetsch" freezing process, which, on a limited scale, was attended with some measure of success, and for a while was regarded by many able judges as the only available mode of treating subsoils of so treacherous and shifting a character. Briefly, the *modus operandi* was as follows:—A large number of pipes were distributed as uniformly as circumstances would allow in and about the unstable site. They were filled with a powerfully freezing liquid, which was maintained in a constant state of active circulation, with the result that in a short space of time the quicksand became solidly frozen. There are two strong objections to this mode. One is that, after the freezing process is discontinued, the sand returns to its primordial condition, which is not one of stable equilibrium and conducive to the permanency and stability of the work, as was exemplified in the application of the Brunlees principle. On the contrary, the quicksand rapidly thaws again, and becomes as unstable as before. It is true that it may be possible during the continuance of the congelation to get in a fairly secure foundation, but the risk is great; and, what forms the second objection, the cost of the whole refrigerating plant, machinery, and appliances is excessive.

Another method of accomplishing the same result is known as the "Neukirch" system, which similarly dispenses with all dredging or excavating of the layer of sand or of sandy gravel, and aims at converting it into a solid mass of concrete by its own automatic agency in the following manner:—By means of compressed-air machines cement or hydraulic lime, in a state of powder, is forced into the sand at a pressure which causes it to form a very intimate mixture, combining with it, and resulting in the creation of, a rough but strong cement concrete. So thoroughly is the permeation and saturation of the sand accomplished, that after the forcing operation is relinquished, the particles of sand, if brought into contact, adhere to one another with the greatest pertinacity and energy. It is well known to those who are conversant with the making of concrete, whether by hand, mixer, or mill, that the product occupies a less volume than that of the sum of the ingredients when free and uncombined. Experience has shown this rule to be strictly adhered to in treating concrete by the Neukirch plan, in which the proportions of the two ingredients are one part by volume of cement to five parts of sand, measured in the same manner. The area of the foundations—or, what is equivalent, the area of the sand to be thus treated—is defined and separated by an ordinary timber casing, exactly as is done in tipping boxes of concrete under water in the building of a pier. As the caisson is intended to last only while the concrete is setting, it may be removed afterwards; but as a rule it is left in the ground. It is not worth while, for the sake of the old timber, to run the risk of drawing the main and sheet piles, and possibly damaging the permanent work. Upon another occasion we shall draw the attention of our readers to one or two other methods of dealing with foundations in quicksands.

◆

BOOKS RECEIVED.

A NEW edition of the *G.E.R. Tourist Guide to the Continent* has just been published. It contains useful maps of Europe and of Continental capitals, as well as many illustrations of Holland, Germany, Switzerland, and the Rhine. A new chapter, "Dull, Useful Information," gives reliable particulars as to the time required for, and cost of, Continental tours. Another practical chapter is that on "Cycling on the Continent," which points out that there is now no duty whatever chargeable on cycles of any description, accompanied by owners, entering Holland, Belgium, or Germany.——The *Antiquary* for July (Elliot Stock) contains an illustrated article on closing-rings and knockers in Norfolk and Yorkshire churches, by the Rev. C. R. Manning, and a continuation of R. C. Hope's papers on "Holy Wells of Scotland." —— The chief contents of *The Reliquary and Illustrated Archæologist* (London and Derby: Bemrose) are an illustrated description of the "Roman Thermæ of Fiesole," by Leader Scott, and an account of the quaint "Churchyard Games in Wales," most of which have now died out, by Elias Owen. The illustrated notes are an attractive feature.——The first number of Vol. III. of the Edinburgh Architectural Association's *Transactions* gives full descriptions of the old buildings visited during the latter part of session 1893-4.

◆

OBITUARY.

WE have to announce the death, at the age of 66 years, of Mr. THOMAS CHATFEILD CLARKE, F.R.I.B.A., F.S.I., which occurred on Friday last at his town residence, 132, Westbourne-terrace, W. Mr. Chatfeild Clarke was born in 1829 at Newport, Isle of Wight, being the eldest surviving son of the late Abraham Clarke. He was apprenticed to a well-known architect in the City, the late Mr. Richard Tress, and after completing his articles spent some time in a large builder's office. In 1855 he commenced practice on his own account in the City, and had since carried on an extensive practice, with offices first in Leadenhall-street, and in later years in Bishopsgate-street Within. In 1859 he married the daughter of the late John Sutton Nettlefold, and of late years had taken into partnership his son Howard. His works include the Royal Bank of Scotland, Bishopsgate-street Within, built upon the site of the Old London Tavern; the London and Lancashire Life Office in Cornhill; Mary Datchelor's Schools, Camberwell; the whole of the schools for the Hornsey School Board; the Parminter Charity Schools; a church and manse in Kensington Mall; Bishopsgate Girls' School, Spital-square; Sydney Chambers, Leadenhall-street; 25, Throgmorton-street; and many blocks of offices in Fenchurch-street, Billiter-street, and on the banks of the Thames; warehouses in Camomile-street and St. Mary Axe; and blocks of artisan dwellings, one of the largest being in Hoxton. He also carried out the Homes for Little Boys at Farningham, a Convalescent Home at St. Leonard's, extensive buildings for the Duke of Westminster on the south side of Oxford-street, the offices for the *Daily News* in Bouverie-street, E.C., and many churches and chapels. Mr. Chatfeild Clarke was surveyor to the Fishmongers' and Cordwainers Companies, for many years. He was a well-known expert in compensation, light and air cases, and of late years had a large practice in compensation cases, and as arbitrator. He joined the Royal Institute of British Architects as an Associate in 1855, becoming a Fellow seven years later, and he served on the council of that body several years since, and read several papers at its meetings, being a prominent supporter of the examination movement. He was one of the original members of the Surveyors' Institution, having joined as No. 27 in June, 1868, and after serving on the council and as vice-president was elected president last year. He was also one of the founders of the Surveyors' Association. He was a justice of the peace for the Isle of Wight, where he had a country residence, Oakfield, Wootton; he held advanced views on land reform and leasehold tenure, was a member of the Reform, Devonshire, National Liberal, and City Liberal Clubs, and unsuccessfully contested Poole, Hammersmith, and Grantham in the Liberal interest. He was a member of the first two School Boards for London, and took an active interest in various philanthropic societies. We gave Mr. Clarke's portrait and a biography in our issue of September 5, 1890.

◆

The seventh congress of archæological societies in union with the Society of Antiquaries was held yesterday (Thursday) at Burlington House, under the presidency of Sir Wollaston Franks. Among the subjects discussed were the better preservation of municipal records, county bibliographies, the treatment of monumental remains, and the present state of the Ancient Monuments Act. The members of the congress dined together in the evening at the Holborn Restuarant, and afterwards attended a reception by the President at the rooms of the Society of Antiquaries.

It is stated authoritatively that there is no foundation for the statement made in the daily Press on Saturday, that the memorial to the late Mr. Frank Holl, R.A., is completed, and that it has been placed in position in St. Paul's Cathedral. The work will not be finished by Mr. Alfred Gilbert, R.A., for some time to come.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

DUNDEE INSTITUTE OF ARCHITECTURE.—The annual meeting of the Dundee Institute of Architecture was held on Thursday in last week, Mr. Leslie Ower in the chair. The annual report stated that there were 51 members and 155 associates on the roll. The income, including a balance of £16 9s. 11d. from the previous year, had amounted to £89 15s. 10d., and the expenditure to £50 6s. 4d. While the Institute might not take credit for much interference with professional matters nor for striking into new and untrodden projects, it could easily be shown that its indirect influence upon the current of the education and life of the profession had been strong, steady, and progressive. The report was approved, and office-bearers were elected.

◆

CHIPS.

Mr. Arthur T. Bolton is the architect, and Messrs. Mowlem and Co., of Pimlico, were the contractors for the new free library for St. George's, Hanover-square, opened last week in Chapel-place North, South Audley-street, W.

The Christchurch, Hants, Town Council have applied to the Local Government Board for sanction to alter and revise their by-laws relating to new streets and buildings in the borough.

The Lancaster Town Council resolved on Friday to apply for borrowing powers for £17,000, in order to open out a new street adjoining the L. and N.W. railway station.

The St. Paul's Schools, Newtown, near Manchester, are being warmed and ventilated by means of Shorland's patent Manchester grates, the same being supplied by Messrs. E. H. Shorland and Brother, of Manchester.

It has been decided to make an addition to the Claughton Concert Hall, Birkenhead, which comprises a large promenade room. The contract has been let to Messrs. McLachlan and Batkin for £600. The plans have been prepared and the work will be under the superintendence of Mr. T. Taliesin Rees, A.R.I.B.A., Hamilton-street, Birkenhead.

The new carillon for the chimes at the Royal Exchange was inaugurated on Monday. The old bells were a suite of fifteen, produced by Dent, and had played a course of four tunes for 50 years. Under the superintendence of Messrs. Gillett and Johnston, of Croydon, thirteen of the bells have been rehung; the other two, being faulty, have been broken up. A new carillon has been erected to play, at the required hours, a series of some twenty-one tunes from three barrels. The tenor bell weighs 40cwt. It formerly had a hammer of 18lb.; it now has one of 40lb.

Last week at the Auction Mart showed an aggregate of £209,769, the highest figure which has as yet been recorded this year for any one week's business. Large landed estates failed to sell, but there was a better demand for residential properties, freehold and leasehold investments of sound character, and for town houses of a moderate class.

The select committee of the House of Lords on the Tower Bridge (Southern Approaches) Bill decided on Thursday to adopt the Betterment Clause, as proposed by the London County Council, without any amendment.

A new clergy-house, which has been erected in the rear of the parish church of Leeds, was opened on Monday. The residence has been designed by Messrs. Chorley and Connon, architects, of Leeds. The basement comprises kitchens and cellars; on the ground floor there are four sitting-rooms for the clergy, a dining-room, an oratory, and a visitors' room; on the floor above, bedrooms are provided for five clergy and for visitors, and accommodation has also been provided for servants. One leading aim of the architects has been so to construct the premises as to minimise labour, and with this view each bedroom intended for the use of the clergy and visitors has been provided with a lavatory and bath. The contracts for the building amounted to £1,700.

On Thursday the historic Bridge-street Chapel, Walsall, one of the leading homes of Nonconformity in the Midlands during the last hundred years, was reopened, after having undergone extensive alterations and additions, including the erection of a front in terracotta and brick in the English Renaissance style. The work was carried out by Mr. Kendrick, builder, under the supervision of Messrs. Bailey and M'Connall, Walsall, architects, and the total outlay was about £2,000.

The Prince of Wales has intimated that Saturday, August 3, will be a convenient date for him to open the new graving dock at Southampton. His Royal Highness is being approached with a view to lay the foundation of a new grammar school for Southampton on the same date.

PASSMORE EDWARDS FREE LIBRARY, HAMMERSMITH.

YESTERDAY (Thursday) the foundation-stone of this building was laid by the donor, Mr. J. Passmore Edwards, at Shepherd's Bush-green, when the Vestry of Hammersmith and the Public Library Commissioners united in arranging a public reception, the ceremony being attended by representatives of all the local associations, of all parties, who combined in advancing the project during the recent poll, which was taken with such overwhelming results in favour of the extra rate to maintain the library when it is completed. We give a reproduction of the half-inch scale detail sheet from the contract drawings, showing the principal entrance which faces the Uxbridge-road. A view of the library and copy of the original plan, now somewhat modified and enlarged in execution, appeared in the BUILDING NEWS for March 29 last, from the architect's perspective drawing, which is now at the Royal Academy Exhibition. The builders are Messrs. W. Johnson and Co., Limited, of Wandsworth. The steel girders and cast-iron columns are contracted for by Mr. R. J. Gifford Read, A.M.I.C.E., of Westminster. Messrs. Burt and Potts are to supply the metal casements, and Messrs. Mellowes' "Eclipse" glazing is provided for the skylights. Mr. Thomas Elsley is to do the ornamental wrought-iron work, and Mr. Aldam Heaton is supplying the quarry glazing. Mr. John Gundry will heat the buildings. Red brick for the walling, with Portland, Doulting, and Box Ground stone dressings, are being used. The Val de Travers Company are supplying the asphalte. Mr. Maurice B. Adams, F.R.I.B.A., is the architect.

ADDITIONS TO PARK HALL, OSWESTRY.

WE publish in our issue of to-day a perspective sketch of the additions to this charming 16th-century residence, which, as most of our readers are aware, is one of the finest examples of architectural grouping in this country. The additions consist of dining and billiard rooms and a saloon on the ground floor, with bedrooms on first floor. The new wing faces the terrace side, which is contiguous to the old portion, and the small building shown on the right is the old family chapel, the return elevation of which adjoins the principal façade of the original edifice, which is well known to all lovers of half-timber architecture. The elevations are treated with thin Ruabon red bricks, the dressings being of red and white Grinshill stone. The main contract has been let to Mr. W. W. Freeman, of Chester, and the plumbing, &c., to Messrs. Isaac Williams and Son, registered plumbers and sanitary engineers, also of Chester, under the architects, Messrs. Thos. M. Lockwood and Sons, of Chester. We gave a view of the entrance front of this fine old mansion in our pages for Feb. 27th, 1891, when a description with detail sketches of the house appeared in connection with our plate.

SKETCHES IN THE TOURAINE.

INTERESTING from its innumerable historical associations as is the valley of the Loire to the historical student, it is far more so to the student of the fascinating architectural style of the Early Renaissance, which, so far, no Englishman has been able to understand or adequately reproduce. Pity it is that the last five Kings of the House of Valois left not memories as pleasing in the annals of their country as their contributions to its artistic possessions. Every charming oriel and every delicate turret has its gloomy association with one or other of this fated race. Almost in sight of the little chapel of St. Hubert at Amboise, perched like a sentry on the outer walls—the first subject of the accompanying sketches—the gay courtiers and ladies of Charles's Court made merry wagers on the numbers of shrieks to be given forth by the tortured Huguenots, and the minutes their sufferings could endure before their last silent agony. Every portion of the majestic pile of buildings, from the Portail of Louis XII. to the galleries of François I., has its own dramatic incident. Here was committed that foul, yet unavoidable, crime which is made the subject of a somewhat stagey picture, by Seymour Lucas, in this year's Academy. The wretched Henry III., after years of sottish pleasures and weak neglect of his duties, only realises the masterful position of the Duke of Guise when he finds himself a prisoner in his metropolis. He makes the midnight flight of a malefactor, and proposes a conference at Blois, when, after a rebuff from the brave Crillon, he persuades De Loignac to assassinate the duke, and thus props his tottering throne a few more wild and wretched months. The room in which the scene was enacted and the chamber below, from which the dying Catherine de Medicis heard the struggle, are within the buildings here portrayed. The old church of St. Nicholas is, of course, of much earlier date. Like most French churches, and, in fact, most things French, the external general appearance is more beautiful and interesting than the interior and details. The small building with the quaint roof I was informed, according to one authority, contained the baths, and, according to another, equally doubtful, the oratory of Catherine de Medicis. My informants apparently confused the location of her physical and moral ablutions. God knows she required both. EDWARD W. JENNINGS.

HULME GRAMMAR SCHOOLS, OLDHAM.

EARL SPENCER has, within the past week or so, taken a leading part in the opening ceremony of these schools, which have been erected from the designs of Mr. John W. Firth, architect, of Oldham, at a cost of about £15,000. The freehold site cost £5,406. The schools are built to accommodate 250 boys and 150 girls, on a plot of land (about eight acres in extent) bounded by Chamber-road, Frederick-street, Hulme-street, and Windsor-road. The buildings are placed on the crown of the hill, with the front to the south-west, overlooking Manchester. The large space of land behind is for the boys for a playground for cricket and football, and the land at the front is for the girls, and is intended to be laid out in terraces, with lawn-tennis grounds, &c., for out-door games. The basement floor contains the gymnasium, which will be used by both, with dressing-rooms for each, a workshop for the boys, and a recreation-room for the girls. Separate dining-rooms are provided, and drying stoves for wet clothing, fitted up with radial horses. There are staircases to ground floor, one at each end, which, together with the corridors and gymnasium, are lined with glazed brick dados. On the ground floor are separate entrances, with offices or waiting-rooms, and private rooms for use of master and mistress. The cloakrooms and lavatories for the boys and girls are placed near the entrances. There is a large central hall, capable of seating about 600 persons, with corridors round it on three sides, from which is access to the various classrooms, 13 in number. All the classrooms have raised galleries, and are lighted from the left; a space of 15ft. (superficial), and a separate desk is provided for each scholar. A chemical laboratory is provided, and is fitted up with benches to accommodate 36 students working at a time, with separate bench on a raised platform for the use of the master. There is also a preparation room adjoining the laboratory, and a chemical lecture-hall which has a raised gallery, with fixed benches for the students, and a large demonstrating table, fitted up with most modern appliances. The style of the building is Gothic (Perpendicular). The whole of the rooms are heated by hot water (low pressure), having ornamental radiators fixed in different parts of the rooms and corridors. The lighting is on the Stott-Thorp principle, with ornamental pendants and gaseliers. Ventilation is effected by fresh-air inlets with Tobin's tubes, and with outlets in the ceilings connected with a large exhaust ventilator on the main roof of hall. The whole of the contract was let to Messrs. C. Schofield and Co., of Oldham. The sub-contractors are:—For excavating and drainage, Messrs. Spencer Brothers; foundations and stonework, Mr. S. Smethurst; brickwork, Messrs. Ogden Brothers; slating, Mr. Joseph Jackson; concreting, Mr. Roger Lowe; steel joists and girders, Messrs. Dorman, Long, and Co.; plumbing and glazing, Mr. J. Kershaw; plastering, Mr. F. Kelly; painting, varnishing, and decorating, Mr. R. Edmondson; facing bricks and terracotta, the Ruabon Brick and Terracotta Company, Limited; the tiling to walls and floors and mosaic, Messrs. Williams and Company, of Manchester; heating, Mr. W. F. Spencer, of Oldham; ventilation, gas fittings, &c., Messrs. James Stott and Company, of Oldham; the desks and laboratory fittings, the Bennet Furnishing Company, Glasgow; the ornamental iron gates and railing, the Art Metal Company, Manchester; iron fencing, Hill and Smith, Brierley Hill, Staffordshire; and the glazing with lead lights, Messrs. Williams and Watson, of Liverpool. Mr. W. R. Norris was clerk of the works.

FIREPLACE, HUTTON COURT, SOMERSET.

WE give to-day a measured drawing, by Mr. K. Gammell, of another of the interesting Jacobean chimneypieces from Hutton Court, near Weston-super-Mare, an ancient manor house modernised, but containing some good specimens of old oak work. On Feb. 1 and May 31 of this year we published other drawings of fireplaces from this house, also by Mr. Gammell, and accompanying same will be found further notes thereon.

GOGAR CHURCH, MIDLOTHIAN.

THE parish church of Gogar, in Midlothian, is picturesquely situated on a rising ground overlooking the Gogar Burn, about two miles west of Corstorphine. The parish of Gogar was in existence at least as far back as 1167. In the statistical account of the parish of Corstorphine, it is mentioned that there was a church or rectory at Gogar, which is mentioned in the MS. "Taxationes Ecclesiasticarum in Episcopatu St. Andrea et Deconatu de Linlithgow," in the year 1167, as Ecclesia de Gogar. In the taxt roll of the Archbishopric of St. Andrew's it is entered as Rectoria de Gogar, and it is included in Keith's list of the parsonages at the Reformation. It was at one time annexed to the Trinity College of Edinburgh. The foundations of the earlier church are still distinct. At what time, or how, this older church was destroyed is not known. A later church of small dimensions, with high-pitched crow-stepped gables, occupied part of its site. It is this later building which has now been restored, and fitted for the needs of modern worship, by means of an addition in keeping with the old architecture. The drawing was exhibited at the recent Royal Scottish Academy Exhibition.

J. A. WILLIAMSON, A.R.I.B.A.

◆

Another stage in the work of restoration now being carried on at the fine church of St. Bartholomew the Great, West Smithfield, from Mr. Aston Webb's designs, was reached on Saturday, when the crypt, which had been disused since the Reformation, was reopened by the Duke of Newcastle. The crypt, originally an ossuary, will in future be used as a mortuary chapel.

The parish church of Manby, Lincolnshire, which has been undergoing restoration, was reopened last week. A new roof, Perpendicular in style, has been put up; the walls have been cleaned of the old plaster, and the stones dressed and pointed; half the church has been reseated with oak seats nicely carved, and the rest filled with chairs, the flooring between the seats being deal block work. The architects are Sir Arthur Blomfield and Sons, and the builders are Messrs. Woodward and Sons, of Louth. The cost, exclusive of special gifts, has been £400.

Building Intelligence.

Bromley, Kent.—An important extension of the Presbyterian Church in England was marked, on Wednesday, 26th ult., by the opening of the new church and buildings in Freelands-road, Bromley. The new buildings, which are of red brick, with Doulting stone dressings, have been erected at a cost of about £8,000, inclusive of fittings; they are Early Gothic in style, with a spire 118ft. high. They comprise a church seated for about 720, a hall for about 240, and a complete suite of rooms admirably arranged for carrying on the various religious and social works of the congregation. Mr. John C. T. Murray, of Old Queen-street, Westminster, is the architect, and Messrs. W. H. Barber and Son, Adelphi, were the quantity surveyors. The general contractor for the work has been Mr. John Bentley, of Waltham Abbey, Mr. Geo. Barber acting as clerk of works.

Carlisle.—Fisher-street Presbyterian Church was reopened on June 27th, having been reconstructed at a cost of about £3,400. The new street front is flanked on either side by a low tower, with high-crested roof rising behind battlements. The church roof is in three sections, there being separate aisle roofs over the gallery on either side, and a large open roof over the nave. Between the nave and gallery roofs, supported on columns resting upon those carrying the gallery, is the clerestory, running along the whole length of the church, and having four trefoil-headed lights to each bay. The chancel arch is carried on red marble corbels. The organ will be placed in position in this chancel during the course of the next month. The pulpit, the gift of the architect, is of oak, octagonal in form, and with stairs on either side at the back. Each side has tracery panels of Late Gothic design. The gallery, providing accommodation for 362, is entirely new, and is carried without trusses. The whole of the inside woodwork, with the exception of the oak pulpit and chair, is pitch pine, varnished. The roofs are slated with Welsh slates, a flèche and tower roofs being covered with Buttermere green slates. The stone walling is of white Lazonby level-bedded shoddies, and the polished dressings are of Prudham stone. Accommodation is now provided for about 800 worshippers. The builders, carpenters, and joiners were Messrs. W. and H. Davidson, Corporation-road; painter and decorator, Mr. W. N. Ballantine, Henry-street; slater, Mr. C. J. Nanson, Lowther-street; heating engineers, Messrs. Musgrave and Co., Limited, Belfast; ventilating engineers, Messrs. E. H. Shorland and Brother, Manchester; stone carver, Mr. J. Hewson, Maryport; wood carver, Mr. Gandy, Fisher-street; stained-glass artists, Messrs. Swaine Bourne and Son, Birmingham; brass and iron gasfittings, and brass pulpit and communion-table desks, Messrs. Jones and Willis, art metal workers, London and Birmingham. The whole of the work was carried out under the immediate supervision of Mr. T. Taylor Scott, of Carlisle, the architect.

The Church House.—The seventh annual meeting of the Corporation of the Church House was held in the new building in Great Smith-street, Dean's-yard, and Tufton-street, Westminster, on June 27th. The report stated that there was every probability that the fabric, irrespective of the fittings, will be completed before the end of the present year. The building consists of offices in the basement, temporary accommodation for the two Houses of Convocation on the ground floor, and the great hall which occupies the whole of the first floor. In the basement there are ten rooms, to be let as offices for church societies. Each room is about 19ft. long by 16ft. wide, and has one large window facing an area lined with white glazed bricks. The ground floor now contains two rooms—one 41ft. long by 29ft. wide, and the other 52ft. long by 29ft. wide—for the temporary use of the Upper and Lower Houses of Convocation respectively. When permanent quarters have been provided for Convocation in that part of the building which will face Dean's-yard, these rooms will be divided into smaller ones for use as offices or committee-rooms. The basement and ground floor will be laid with pitch-pine blocks bedded in damp-proof cement upon a fireproof floor. The doors and all the other wood finishings in the basement and on the ground floor are of pitch-pine. The great hall, which is reached by a double staircase from the main entrance in Great Smith-street, is 115ft. long by 50ft. wide, and, with the galleries, will accommodate about 1,200 persons. The platform will be at the east end, opposite the main entrance. Behind it will rise the organ, now being built by Messrs. Lewis and Co., of Brixton, the gift of the Hon. Richard Strutt. The roof and all the other woodwork of the hall, together with the flooring, is of oak. The building will be lighted throughout by electricity. The ground floor and hall will be heated by hot water; but the offices in the basement will have ordinary fireplaces. The exterior is faced with red brick and dressings of Portland stone. For all the interior stonework Ancaster stone is used. The architect is Sir Arthur W. Blomfield, A.R.A.

Dorking.—The new Roman Catholic church of St. Joseph at Dorking, opened on Wednesday week, has been built from designs by Mr. Frederick A. Walters, F.S.A., of Westminster, and is Early English in style. It is constructed, externally, with Godalming stone, with Bath stone for the windows and dressings, the roofs being covered with red tiles. The plan consists of a wide nave and aisles, with square-ended chancel, and two side chapels. The tower, when completed, will stand on the south side of the chancel over one of the chapels, and will be of rather short and massive proportions, sacristies and organ-chamber near the chancel completing the arrangements. The interior is lofty. The roof of the chancel is vaulted, those of the nave and aisles being of wood painted. Owing to the nature of the site there is a considerable flight of steps up to the main door, and the chancel floor is again raised by more steps about 3ft. above that of the nave. The high altar, which thus stands out very prominently, is supported by clustered grey marble columns, and has a low retable for candles and crucifix, the tabernacle of circular tower form standing in front of the retable. Behind the altar, and against the east wall, a lofty reredos will eventually be erected, with a canopied throne, supported by angels in the centre. Accommodation is provided for about 500 persons at present, with one of the aisles temporarily omitted.

Kennerleigh, Devon.—The parish church of St. John was reopened on June 24. The small building consists of nave, aisle, and chancel, with a low, square tower at west end. Previous to the commencement of the work, the damp and narrow aisles were paved with cobble stones and roughly squared blocks, deal horse-box pews choked the nave, and two of the windows had wooden mullions and were partly unglazed and rotting. A gallery blocked the western end, he roof-plastering was falling in, and ivy growing through the ceiling. The gallery and pews have been demolished, the floors uprooted, and a bed of concrete, 6in. thick, spread over the whole of the floors, which have been laid with oak-block paving throughout. The nave has been reseated with open benches of English oak, with moulded top rails and bench ends, a portion containing tracery carvings. Some old oak benches have been restored and placed in the north aisle; these have ends and seats, varying from 4in. to 5in. in thickness. The walls have been lined with oak dado boarding, and the walls above restuccoed. Inner stone sills have been added to all the windows, and wooden mullions replaced by stone. The chancel is approached by two steps of blue limestone. Moulded oak choir-stalls occupy the chancel, and there are a new reading-desk and hexagonal pulpit, both in oak. The tower-arch has been filled in with an oak screen, with tracery panels and battlemented cornice. Messrs. W. Dart and Son, of Crediton, were the builders.

London County Council.—At Tuesday's meeting of this body the adjourned report of the Public Health Committee was adopted. This recommended that the work of erecting the superstructure of the dwellings on plots 1, 2, 3, and 4, comprised in the Shelton-street improvement scheme, be executed by the Council without the intervention of a contractor; but that, in the event of the Works Committee not being satisfied of the sufficiency of the estimate, the Public Health Committee be authorised to invite tenders for the work. The same committee recommended that the Council should itself prepare a scheme for dealing with the Falcon-street area, St. George the Martyr; the cost to the Council would be £7,750, but that entirely excluded any provision for rehousing. This led to a long discussion, and it was eventually amended by the addition of a proviso that the Council may obtain powers to divest itself of the responsibility of building and managing the buildings erected on the lands acquired. A recommendation of the same committee for the employment of a specially qualified architect to prepare plans for the erection of working-class dwellings on the Millbank Prison site was, after long debate, referred back to the committee. The Asylums Committee reported that at the present moment all the beds in the asylums were full, and that they had 1,156 patients in out-county asylums under contracts. They, therefore, recommended that temporary iron buildings be provided for 300 patients at Banstead asylum and 300 female patients at Colney Hatch; and if further accommodation were required, to make similar provision for 250 females at Cane Hill. The estimated cost of providing this accommodation was £40,000. It was decided to take steps for the immediate provision of this temporary accommodation as recommended.

Wapping.—The Bishop of Stepney, on Saturday last, dedicated the new Baptistery which has been erected at St. Peter's, London Docks, in memory of Father Lowder. The building is constructed of red brick and stone, and is groined in the same materials, the vault forming a pointed dome with intersecting Welsh groins, which divide the sides into two bays, following the method illustrated so well in the S.W. chapel of the nave of Lincoln Cathedral. The windows are filled with geometric tracery, and the glass was supplied by Mr. Aldam Heaton, of Bloomsbury. The carving of the Evangelistic Beasts, introduced on the pillar which carries the hoist beam above the stone lintel spanning the staircase, was executed by Mr. Nathaniel Hitch, who did the sculpture of the angel figure by the font and other enrichments. The wrought-iron grilles and elaborated crane, which supports the chain carrying the font canopy, were carried out by Messrs. Hart, Son, Peard, and Co., and Mr. Thomas Elsley made the wrought-iron and brass gas-fittings. The builders are Messrs. Ashby and Horner. We illustrated the interior of the Baptistery in the Building News for May 11 last year from the drawing then on view at the Royal Academy. The architect is Mr. Maurice B. Adams, F.R.I.B.A.

Westminster.—The foundations of the new Roman Catholic cathedral of Westminster were blessed and the first stone was laid on Saturday by Cardinal Vaughan. The new building will occupy a site of an oblong shape between Ashley-gardens, Ambrosden-avenue, Francis-street, and Carlisle-place. At first, it will be remembered, it was intended to reproduce the ancient basilica of St. Peter, but the idea was abandoned as impracticable. Mr. J. F. Bentley, the architect, in his revised scheme, provides a building 350ft. long, 156ft. wide, and 90ft. high, and covering an area of 54,000sq.ft. The nave will be 240ft. in length, with 60ft. of clear width; and there will be transepts, aisles, and side chapels. In the apse, the floor of which will be raised some feet above the level of the nave, will be the monks' choir, visible from the main entrance. The canons' stalls will be in the sanctuary. A figure of Christ Crucified over the high altar will be the central feature. The style is Byzantine, like that of the church of Sant' Ambrogio, at Milan, with certain details suggested by San Marco of Venice and San Vitale of Ravenna. The characteristic of the building will be the great open span of the nave and transepts. The cost of the structure may be £150,000, towards which, it was announced on Saturday, over £55,000 has been promised. The cathedral will be dedicated to "The Most Precious Blood," and it is hoped to finish the building within two years, so as to honour the 13th centenary of the landing of St. Augustine in England by the opening of this Metropolitan cathedral.

* * *

Mr. A. Marshall Mackenzie, A.R.S.A., architect, Aberdeen, has visited and inspected New Mar Lodge in connection with the Duke of Fife's intention to erect a residence which will take the place of the lodge recently destroyed by fire.

The chairman of the Wilsden District Council, on Saturday afternoon, opened the valve at Manywells Heights meter-house, to allow the flow of water from the Bradford Corporation mains to run into those newly laid at Wilsden. The water comes from Thornton Moor Reservoir, situate at a height of 1,250ft.; the Wilsden levels are from 900ft. to 600ft. above Trinity mark, and there is a water-pressure at Ling Bob, the upper end of the village, of 200lb. to the square inch, and 250lb. at the Brewers' Arms, situate at the bottom of Wilsden.

Engineering Notes.

Glasgow.—The Glasgow Harbour Tunnel, which passes under the Clyde at Stobcross, was opened on Monday. Parliament, in 1889, sanctioned the scheme. The tunnel connects Mavisbank Quay, on the south side, with Finnieston and Stobcross Quays, on the north side, and consists of three tunnels, 16ft. in diameter, the side ones for vehicular traffic, and that in the centre for the passage on foot. The approach on either side is by a circular shaft, 80ft. in diameter, in which are operated the hydraulic hoists, raising and lowering the vehicles as they leave or enter the tunnels. The shafts are formed of cast-iron segments, and lined with brickwork. The tunnels themselves are also lined with cast-iron segments, filled-in with concrete and lined with glazed brick, presenting a particularly neat and pleasing appearance. All the tunnels were driven by means of shields and compressed air. The outer skin of the segments was coated by grouting with Arden lime, blown through a hole in the lining by air pressure. Each shaft contains six divisions for as many lifts, half being devoted to ascending, and half to descending, traffic. The maximum weight allowed for is about five tons, and the speed about 4ft. per second. The hoisting appliances have been supplied by the Otis Elevator Company, Limited, of London, and embody all the latest types of design, the pressure maintained by a pair of accumulators being 750lb. per square inch. The company are represented by Mr. Furman. The engineers of the undertaking were Messrs. Simpson and Wilson, C.E., of Glasgow, whilst the tunnels and girder work were executed by Messrs. Hugh Kennedy and Sons, of Partick, and Messrs. Alex. Findlay and Co., of Motherwell, respectively. The tunnels for vehicular traffic will be opened shortly.

Society of Engineers.—A visit was paid by this society on Wednesday to the Outer Harbour Extension Works, the existing harbour, and the Electricity Supply Co.'s Station, at Dover. The outer harbour now under construction at Dover has been designed for commercial purposes, and not as a harbour of refuge, the chief object being the provision, in all states of weather and tide, of accommodation for the embarking and landing of passengers on and from 'cross-Channel steamers. The contemplated works consist of :—(*a*) An extension of the Admiralty Pier, 580ft. in length, running approximately in an easterly direction; (*b*) an eastern arm starting near the clock tower, total length 2,760ft.; and (*c*) the reclamation of about five acres of the sea-bed, between the shore end of the Admiralty Pier and the entrance to the existing Inner Harbour, with two large steamer jetties projecting therefrom. The work now under construction, as a first instalment of the complete design, is the east pier (*b*), the contract for which is being carried out by Sir John Jackson, Messrs. Coode, Son, and Matthews being the engineers. The first 1,260ft. of this work will be an iron viaduct in bays of 40ft., except at three points in its length where stiffening bays of 20ft. span and of greater width will be added to give lateral rigidity to the work. The main part of the viaduct will have a uniform width of 30ft., including a footpath 6ft. wide on each side. The deck is at a level of 19ft. above high water of spring tides. In consequence of great irregularity in the quality of the chalk bottom, the centre pile of each bay is fixed on a cast-iron cylinder, filled with concrete, after being sunk well into the solid chalk; the outer piles have cast-steel screws 4ft. in diameter. The superstructure is formed of three rows of lattice girders, properly braced, carrying corrugated decking, on which the roads and footpaths will be formed. The gutters, curbs, and nosings are of cast iron. The direction of the viaduct is approximately south-east. Its outer end will abut on the solid portion of the pier, this latter being 1,500ft. long. For about 400ft. from its commencement, the solid work will follow the same south-easterly direction as the viaduct, but thereafter it will gradually curve to the south and south-west. The entrance between the head of the East Pier and the end of the Admiralty Pier extension will be 450ft. in width. The blocks in this solid work will range from 12 to 20 tons in weight. Above low water they will be faced with granite, and will in all cases be founded on the chalk, into which they will be sunk a depth of about 3ft. The top width of the pier will be 35ft., and the coping level 10ft. above high-water spring tides, the difference between the level of this portion of the work and that of the viaduct being met by an incline with an easy gradient. On the seaward side there will be a parapet 10ft. wide, somewhat similar to that on the Admiralty Pier. The pier will be finished by a circular head, 55ft. in diameter, on which a lighthouse will be built. The extension of the Admiralty Pier (*a*) will be of a similar character of construction to the outer portion of the existing work, but it is proposed to use concrete blocks of greater weight than those in the present structure. As soon as sufficient shelter is obtained from works (*a*) and (*b*), it is proposed to commence the reclamation (*c*) and the two steamer jetties, each 400ft. long and 100ft. in width. These jetties will be furnished with landing stages, and will practically form covered stations into which the trains of the L.C. and D. and S.E. Railways will run. The bed of the harbour will be dredged so as to give a minimum depth of 15ft. at low water of ordinary spring tides alongside the jetties and in their vicinity. The sheltered area of the new harbour, when completed, will be 56 acres. The Admiralty Pier affords protection to the western side of the new works. There are now two basins, one known as the Wellington basin of about 3½ acres, with gates of 70ft. opening, and the other, the Granville basin of 4¾ acres, with gates of 65ft. opening. The present outer harbour of 13½ acres will become an inner tidal harbour at the completion of the extension works. A new lighthouse with a masonry tower surmounted by a lantern of the fourth order, is being erected at the turret end of the Admiralty Pier, and the slipway at the upper end of the Wellington basin is capable of hauling up a safe load of 800 tons. The river Dour discharges into the harbour upon the upper or North side of the Wellington dock. Mr. A. T. Walmisley, M.Inst.C.E., as engineer to the Dover Harbour Board, has charge of the Admiralty Pier and inner harbour.—The entrance to the lighting station is by a private road leading from Park-street. The building consists of offices occupying the west portion, and adjoining these are the engine and boiler rooms. The engine room, which is faced with glazed bricks throughout, is 100ft. in length by 30ft. in width; the boiler-room is 100ft. long by 45ft. There is a circular chimney shaft 120ft. in height. The contract for the whole of the machinery has been, and is being, carried out by the Brush Electrical Engineering Company, Ltd. The engineer and manager is Mr. A. J. Lawson, and the resident engineer, Mr. A. A. Whitlock.

The St. Helen's and Lowton Railway.—The new railway from St. Helen's to Lowton, near Leigh, opening out connection with the lines of the Manchester, Sheffield, and Lincolnshire Railway Company, and providing direct communication with the eastern, midland, and southern counties, has just been completed, and was opened for goods and mineral traffic on Monday. It is the first section of the St. Helen's and Wigan Junction Railway which will eventually connect two portions of the great railway systems under the control of the Cheshire Lines Committee by means of 18 miles of rails to be laid from Fazakerley and West Derby on the Liverpool side to Golborne and Lowton on the Manchester side of the borough of St. Helen's, passing through Knowsley, Eccleston, St. Helen's, Haydock, Ashton, and Golborne. The new line, eight miles in length, passes through the heart of an extensive coalfield covered by 16 or 17 collieries. All the station buildings along the line are designed in a modified phase of the Queen Anne style. Leaving Golborne station the line is carried westward on three massive bridges over Wigan-road, and the adjoining four sets of rails constituting the main line to Scotland of the London and North-Western Railway Company. The erection of these bridges formed the heaviest work of the kind encountered in the construction of the new railway. The railway afterwards enters a deep cutting some three miles in length, and goes through a subway about 100 yards in length, underneath the extensive central colliery sidings of Messrs. Evans and Co. Its sides are of solid cement, 6ft. thick, lined with glazed blue bricks, and the rails belonging to Messrs. Evans and Co. are carried over the cutting by Hobson's steel floors, of similar design to that used for the Liverpool Overhead Railway. The St. Helen's station, with its sidings, platforms, warehouse, booking office, &c., has a total area of about eight acres; pending the continuation of the line to Liverpool, the buildings are but of a temporary character. The contractors are Messrs. S. W. Pilling and Co., of Manchester; Sir Douglas Fox and Mr. Francis Fox, of Westminster, are the chief engineers; Mr. J. Keith, of Golborne, is resident engineer; and Mr. W. G. T. Hallett, of St. Helen's, superintendent of the architectural department.

CHIPS.

The members of the Birmingham and Midland Institute made an excursion on Wednesday week to Shipton-under-Wychwood, inspecting the church there, the still finer one at Burford, and the Priory House, the seat successively of the Tanfields, Falklands, and Speaker Lenthall, and Shipton Court, an Elizabethan residence still occupied.

Colonel Luard, C.E., held an inquiry at the town hall, Huntingdon, on Tuesday week, respecting an application for a loan of £1,600 for improvements and alteration to the borough waterworks. Mr. J. P. Maule (deputy town clerk) went into details of the waterworks scheme from its foundation in 1872, and said that the engines had got out of order, and gas-engines, new mains, and other improvements were required, at a cost of £1,500. A scheme and plans by Mr. Middleton, C.E., were laid before the inspector.

A subscription full-length portrait of Lord Russell, of Killowen, in his robes as Lord Chief Justice, is to be painted by Mr. Doyle Penrose, and on completion will be hung in the central panel of the large room of Hackney Town-hall.

Mr. Willcocks, C.E., held an inquiry at Llandudno on Friday respecting an application by the rural district council of Llechwedd to the Local Government Board for power to obtain a loan of £3,000 for works of sewerage in their district. Evidence was given by Mr. T. B. Farrington, C.E., the engineer in charge of the scheme, and others.

The Sopley School Board have resolved to erect a new school at Ripley. Messrs. Hawker and Mitchell, of Bournemouth, are the architects.

Representatives of the various Temperance organisations of Keighley met on Saturday afternoon to lay the foundation stone of their new premises now being erected at the corner of North and Albert-streets. The building, designed by Messrs. W. and J. B. Bailey, is intended to accommodate on three floors all the Temperance agencies of the town and district. The cost is estimated at £5,687, without site or furnishing.

The Prince and Princess of Wales will open the new front building of the Royal Free Hospital, Gray's Inn-road, on Monday, July 22nd.

Messrs. Norman, Sons, and Beard, of Norwich, the contractors for the new organ at Bath Abbey, have taken possession of the building with a staff of fifteen workmen, who are building the instrument, which will occupy practically four positions in the church. Two large wind chests are already placed at a high level on the north and south sides between the piers supporting the tower. On these will be placed the sounding boards and metal pipes with ornamental fronts. To support these structures girders have been fixed into the piers. The wind chests are to be incased in carved oak panelling. The pedal organ will be in two sections in the north transept, one portion against the west wall and another against the east wall. The manual and organist's seat will be almost immediately behind the pulpit. The total cost will be £3,000.

Memorial stones of a Wesleyan chapel have been laid in Eastgate, Bramhope, near Leeds. The building will be Decorated in style, and will comprise nave, transepts, chancel, and organ recess. A tower and spire is to be placed at one angle, rising to a height of 120ft. The exterior is to be built of wall-stones from Apperley and Bradford, with ashlar dressings from Guiseley. The interior woodwork will be of pitch-pine. Behind the church are schools, classrooms, and vestry, and a detached house for the caretaker is to be built at the back. The chapel will accommodate 170 persons, and the cost will be about £2,200. The architect is Mr. W. J. Morley, F.R.I.B.A., of Bradford and Harrogate; and the contractors are: Mr. Lawrence, mason, Horsforth; Mr. S. Kaye, joiner, Poole; Messrs. Shuttleworth and Sons, plumbers, Otley; Mr. W. Walker, slater, Otley; Mr. A. Taylor, plasterer, Eccleshill; and Messrs. Couldwell and Sons, painters, Leeds.

The new altar of the Sacred Heart, erected at the east of the aisle recently added to St. Osmund's R.C. Church, Salisbury, opened last November, is now completed. The altar is of oak, in the 15th century style. In the centre of the altar, beneath a carved canopy, stands a statue of "The Sacred Heart," by a Paris artist. On either side there are two panels containing paintings on gold ground. The subjects selected are "St. Elizabeth of Hungary," "St. Frederick," "St. Dominic," and "St. Barbara." These paintings have been presented to the church by Mr. E. Doran Webb. Above the altar is a rose window, the central figure being the Lamb resting on the book with seven seals surrounded by cherubs.

COMPETITIONS.

Lancaster.—The Lancaster School Board have placed first the plans sent in by Mr. Robert Walker, F.R.I.B.A., architect, Windermere and Lancaster, under motto "Up to Date," for a large board school for 1,000 children, to be built in The Marsh, and have instructed him to proceed with the first part of the work without delay.

Nottingham.—In a recent limited competition for new chapel and Sunday-school for the United Methodist Free Church, Gregory Boulevard, Nottingham, the design of Mr. F. W. Dixon, architect, of Oldham and Manchester, has been selected. There were nine competitors.

Sowerby Bridge School Board.—The monthly meeting of the Sowerby Bridge School Board was held at the offices, Tuel-lane, this week. The Board, prior to the meeting, met in committee to consider the plans sent in in competition for the new school to be erected at Bolton Brow. Four sets of plans had been received, and those endorsed with the *nom de plume* "Up-to-Date" were unanimously selected as giving greatest satisfaction. This decision was confirmed in the board meeting, on the proposition of Mr. Bancroft, seconded by Mr. Swallow. The envelope accompanying the plans was then opened, and it was found that they were the design of Messrs. C. F. L. Horsfall and Son, Halifax, who were appointed architects for the new building. It was ascertained that the authors of the other plans sent in were Messrs. G. Buckley and Sons, F.S.I. (Halifax), Mr. S. Wilkinson (Sowerby Bridge), and Mr. C. H. Hebblethwaite, A.R.I.B.A., P.A.S.I. (Halifax). The following were the conditions of this competition :—"No premium will be awarded for any set of plans; but the author of the selected plans will be appointed architect for the proposed schools, to prepare all necessary plans, tracings, and specifications; to supply bills of quantities to the various contractors free of charge; to take the entire responsibility (without a clerk of the works) of superintending the works; to measure up the same when completed; to hand over to the board on the completion of the works, the plans and specifications; his remuneration for the whole of these duties to be at the rate of three pounds and ten shillings (£3 10s.) per cent. upon the total cost of the erections, exclusive of the cost of land and school furniture." The competitors had to survey the site for themselves !

CHIPS.

A new organ, built at a cost of £300 by Messrs. Blackett and Howden, of Newcastle-on-Tyne, was opened on Wednesday at the Methodist Free Church, Whitley.

Mrs. Ishmael Jones, of Trelawny Towers, laid at Flint, on Monday, the foundation-stone of a new Welsh church, to be built as a memorial to her late husband.

The council of the Institute of Civil Engineers of Ireland has awarded a Mullins gold medal to Mr. W. Kaye Parry, A.M.I.C.E., for his paper entitled "The Application of Recent Advances in the Study and Treatment of Sewage."

Some alterations are about to be made to improve the auditorium of Collins's Music Hall by Messrs. Dearing and Son, of Islington, under the direction of Messrs. Sachs and Woodrow, architects.

Mr. Thomas Egbert Lidiard James, F.R.I.B.A., of Halton House, Balham-hill, S.W., was married on June 27 to Margaret Hester Paske, only daughter of Mrs. Crozier, Grafton-square, Clapham, S.W.

The Bishop of Colchester consecrated, on June 27th, the Church of St. Chad, Chadwell Heath, Essex. The foundation-stone was laid in 1884 by Mrs. Claughton, wife of the late Bishop of St. Alban's, and the church was licensed for public worship in 1886. The building is Perpendicular in style, of red brick and stone facings, and Mr. F. Chancellor, of London and Chelmsford, was the architect. The tower and vestry are yet to be built, and the blocks of the building remain uncarved. The cost of the church has been £3,000.

At the Whitchurch, Salop, County Court last week, Mr. Walter Webb, architect, Whitchurch, sued William Lister for the sum of three guineas for preparing a plan for building sites on land in Wrexham-road. Plaintiff's case was that he received instructions from Mr. Bates, defendant's agent, to prepare a plan, and this he did in August last. Three houses had been erected practically in accordance with the plan produced. The defence was that the plan was only a sketch, to which plaintiff replied that it was not inked-in, as defendant was in a hurry to begin work. Judge Hughes awarded plaintiff two guineas and costs.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—J. E. Russell.—Alpha.—C. W. (Chester).—Perplexed.—J. T. and Co.—F. E. R.—E. S. and Co.

Intercommunication.

QUESTIONS.

[11372.]—**Bonding Walls.**—Can any of your readers state why front walls of houses are not bonded with the party-walls, as I have come across many such cases in houses built early in the present century? The ends of the party-walls are complete. There is no bond whatever with the front and back walls of several houses in a terrace in several separate and distant streets.—H. Lovegrove.

[11373.]—**Footings.**—Has anybody been able to fix the date when projecting footings came in, as in many cases of underpinning, the walls of houses start on the earth, without the usual and modern spread of footings?—H. L.

[11374.]—**Wood-carving.**—What are the conditions of the wood-carving competition instituted by the Company of Carpenters?—Carver.

[11375.]—**Northamptonshire Churches.**—Any information about the chief features of the principal churches in Northamptonshire will be thankfully received. Their interior features are, I believe, worthy of study.—Bicyclist.

[11376.]—**Right of Support.**—If an excavation of ground is made, and causes subsidence of adjoining premises, can the owner of latter claim damages. The excavation was of a very slight depth, and the house very old and rickety.—Box.

[11377.]—**Water Colours.**—Which are the most effective tints for stone buildings, old and new, in light and shadow? Any hints, or a few combinations of pigments, will oblige.—A Sketcher.

REPLIES.

[11369.]—**Commission.**—Young architects get what they can out of house-agents in a lump sum for work done in the preparation of drawings; but if the agent simply introduces the work, and the architect gets the usual charges, with his name appearing, about one-third is allowed for the introduction.—H. L.

The annual soirée of the Institution of Electrical Engineers was held on Wednesday night in the galleries of the Royal Society of Painters in Water Colours, which were crowded. The President, Mr. R. E. Crompton, and the Council received the guests.

Legal.

TENANTS' FIXTURES.

ALTHOUGH the fixtures upon the premises he occupies may certainly and clearly belong to the tenant, he must take care to remove them before his term expires or his tenancy is determined, because, even though he holds over, the mere possession of the premises will not give him a legal right to remove them afterwards. Such, at all events, seems to be the present state of the law, although if the recent case of "Barff v. Probyn" (*Times*, 22nd June), in which the point lately arose, is taken up to the Court of Appeal, it may be reconsidered. This action was brought by the plaintiff, as lessor, against the defendant, as assignee, of the lease of a public house in London, to recover the value of certain trade fixtures which the defendant had removed after his term expired, and while an action of ejectment was actually pending against him. His term had run out in September, 1893; but because the person to whom he had sold his fixtures for £90 had not paid for them, he simply held over until this matter was settled. The plaintiff had, therefore, to issue a writ in ejectment, and when the defendant went out in March, 1894, as the result of these proceedings, it was found the fixtures had been removed meanwhile.

The plaintiff's contention was legal and logical, he maintaining that after the admitted expiration of the defendant's term in September, 1893, he became merely a trespasser, and had therefore no right to remove even his own fixtures. On the other hand, it was argued for the tenant that as he removed his fixtures while he was in possession of the premises, although he was holding over, the removal was legal. Mr. Justice Charles was desirous of taking that view if he could, as he thought it rather hard the tenant should lose all his fixtures, and there was one case in the books that seemed to support that contention. But, on the other hand, the general current of authority was to the contrary effect, and it appeared to be laid down in several cases that a tenant could only remove his fixtures during his tenancy. He therefore gave judgment for the plaintiff, but with a stay of execution to appeal, and he only gave the plaintiff the break-up sale value of the fixtures on the ground that as the public-house was at once going to be pulled down that was all he could rightly claim.

Fred. Wetherfield, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

F. J. B.—Libel.—Postcard.—Discount.—There is nothing legally libellous in this word, especially as, if the whole card be read, it shows what was meant, and that it has nothing to do with lending money.

D. C. L.—Contract.—Building.—Architect.—(1) No, I think not. (2) Not usually. (3) No. (4) Yes, if the contract is so drawn. (5) The architect's certificate is generally final, and cannot be upset.

A new wing added to the hospital at Gravesend was opened last week. The extension has cost £6,700, and raises the accommodation to 52 beds for adults, and 14 for children.

A new parish room for St. Barnabas, Tunbridge Wells, was opened on Thursday in last week. It is placed at the junction of Stratford-street and Lower St. James's-row, is built of red brick with stone dressings, and cost £1,850. Messrs. Cronk were the architects, and Mr. Judd the builder.

The members of the Hampshire Field Club held a meeting in South-east Hants on Thursday in last week, the rendezvous being at Chalton, the church of that village being first inspected, and a visit to the neighbourhood of Butsey Hill and Catherington was afterwards made, Mr. Shore, of Southampton, acting as guide.

Among the recipients of ministerial honours is Dr. Henry D. Littlejohn, of Edinburgh, who is knighted. He has a wide reputation as an authority in matters of public health and medical jurisprudence. For years he has been officer of public health for the City of Edinburgh, and in a wider capacity he has come before the public as officer of health to the Board of Supervision in Scotland. The British Institute of Public Health, when they held their annual Sanitary Congress in Edinburgh a few years ago, elected Dr. Littlejohn to the presidential chair, and the University of Edinburgh at the same time conferred upon him the honorary degree of LL.D.

LEGAL INTELLIGENCE.

Superintending Architect's Power to Determine Building Line.—Allen and Another v. London County Council.—In the Queen's Bench Division, on Monday, Mr. Justice Wills and Mr. Justice Wright heard a special case stated by a Metropolitan magistrate, who had made an order for the demolition of a certain building in the Metropolis as being beyond the building line. The question raised was whether the decision of the architect as to the building being beyond the building line was conclusive and binding on the magistrate. A complaint had been made to the magistrate by the London County Council that the appellants began to erect a building beyond the general line of buildings on the north-western side of Birchington-road, Kilburn, without the consent of the County Council, contrary to section 75 of the Metropolis Management Act, 25 and 26 Vic., c. 102. The appellants, on November 13, 1894, began to build four shops and houses upon the land at the corner of Birchington-road, Kilburn High-road, having a frontage of 22ft. to Kilburn High-road, and 58ft. to Birchington-road. This front in Birchington-road extended 16ft. beyond the general line of buildings, as determined by the certificate of the superintending architect of the London County Council, who stated in it that the main fronts of the buildings in a certain row of houses formed the general line of buildings on the north-western side of Birchington-road, "in which road the building in question is situate, and the building in question would project beyond the prolongation of the said general line." It was contended on behalf of the appellant that the architect had not by his certificate found that the building was situate in the "street, place, or row of houses" described as the north-western side of Birchington-road, and if he had so found, he had placed the building in a "street, place, or row of houses" in which the same was not situate. The respondents contended before the magistrate that the certificate had determined that the building was situate in Birchington-road, and that such determination was binding on the magistrate. The magistrate adopted this view on the authority of the case "London County Council v. Cross," and directed the demolition of so much of the building as was beyond the line. The question for the Court was whether the certificate showed that the house in question was situate in the street, place, or row of houses on and for which the general line of buildings was determined; (2) whether it was the duty of the architect to decide and find the situation of the appellants' building, and, if so, whether his decision was binding on the magistrate. The Court decided in favour of the London County Council, and gave judgment accordingly. Mr. Justice Wills said the question raised was whether the certificate of the superintending architect of the London County Council, who now represented the Metropolitan Board of Works under the Metropolis Management Act of 1862, deciding whether a particular building to which the building line applied in a street was decisive of the point in dispute. Looking at the Act apart from the authorities, the learned Judge would have thought that the tribunal which should decide that was the magistrate. But the matter had been much discussed both in the Divisional Court and in the House of Lords. It could not be said that the authorities were satisfactory. In 1886, in the case of "Barlow v. Vestry of St. Mary Abbott's, Kensington," Lord Watson held, without hesitation, that the architect was the person to decide, while Lord Bramwell equally unhesitatingly held it was the magistrate. Lord FitzGerald agreed with Lord Watson. The majority of those learned Lords, therefore, were against the view that the magistrate was the deciding tribunal. The point also came before the Divisional Court in "London County Council v. Cross," where Mr. Justice Denman and Mr. Justice A. L. Smith both adopted the view that the architect was the person. It was true that the case was subsequently overruled on another point, and, therefore, could not be called a binding judgment; but it seemed better to follow the views of this majority of Judges rather than to set up his own opinion. The point was not so important as it might seem, because the London Act of 1894 had made provision for the appointment of a tribunal of appeal against the architect. On the second question the architect must be taken as meaning to decide and determining that the building in question was in the street to which the building line applied. Mr. Justice Wright, solely in deference to the judgment of the other Judges, concurred. Mr. Wedderburn, on behalf of the appellants, asked for leave to appeal if leave were necessary. This was granted, as of course.

In re Hayward and Son, Bournemouth.—At a sitting of the Poole Bankruptcy Court on Wednesday week, John Hayward and Frank Hayward, trading as Hayward and Son, builders, Bournemouth, came up for public examination. Their statement of affairs shows gross liabilities amounting to £2,870 3s. 7½d., of which £1,281 17s. 11d. is expected to rank for dividend. The net assets, including a sum of £258 10s. 10d., an estimated surplus from securities in the hands of creditors fully secured, are only put at £306 2s. 7½d., showing a deficiency of £975 15s. 3½d. The debtors allege that bad trade, inability to realise property, and want of capital are the causes of their failure. They first commenced business, they stated, in 1889 with a joint capital of £500. In 1890 they took in Mr. Penton as a partner; but in 1892 the partnership was dissolved, and a deed of assignment was given on behalf of the creditors, who received a dividend of 6s. in the pound. The Official Receiver points out that even had the debtors been able to realise the £258 10s. 10d., estimated as the surplus on properties, there would still be a deficiency of £975 15s. 3d. to be accounted for. Frank Hayward, the son, was the first examined, and in answer to questions admitted that he knew of his insolvency some months before he filed, but that they had nevertheless gone on contracting debts. The debtor admitted that several warrants were served upon him by the Sheriff in January, February, and March, that he had still continued ordering goods, and that the goods were still unpaid for. John Hayward, the father, admitted that he had never properly looked into his affairs to see how he stood, and that he must have been insolvent for some time past. The Registrar thought this was one of the worst cases that had been before the Court for some time past, and assented to an application that the further hearing should be adjourned to the 31st July, to allow of some books being produced, and of further information being given.

What is a Sky-Sign?—The representatives of the Savoy Hotel (Limited) appeared at Bow-street Police-court on Tuesday to a summons issued at the instance of the County Council, charging them with unlawfully retaining a sky-sign without the license of the County Council, contrary to Section 128 of the London Building Act, 1895. Mr. Chilvers appeared for the Council, and Mr. Marshall Hall for the company. Mr. Chilvers described the sign to which exception was taken, and, after quoting sections of several Acts, argued that it was a sky-sign within the meaning of the law. He called Mr. George Townsend, a surveyor in the employ of the Council, who said that the sign was fixed to the roof of the Savoy Hotel. It consisted of a series of boards in three sections, to which large embossed glass letters were attached. The letters, which were about 7ft. high, formed the words "Savoy Hotel and Restaurant," on three different sides of the hotel. The sign was fixed to the roof and chimney stacks. Witness, in reply to Mr. Hall, said he had heard that the sign as it now appeared had been suggested by the district surveyor. Mr. Marshall Hall said the large letters, "Savoy Hotel and Restaurant," were originally put on the roof of the hotel as a protection for the servants when duty or pleasure took them there. It was a dangerous roof, at a high elevation, and some protection was required. Originally, these letters had nothing but the sky behind them, and they undoubtedly formed a sky-sign. Then the district surveyor suggested that a board should be put behind the letters. This was done, and he urged that the letters as they now stood were not a sky-sign within the meaning of the Act. It was perfectly clear that the object of the Act was to protect the public against dangerous and unsightly signs. In this case the sign was neither dangerous nor unsightly. It was an advertisement, certainly, but not a sky-sign. It had been said that in certain parts the sign was slightly raised from the roof, but that was merely to let the rain-water run away. Mr. Chilvers admitted that there were a great many cases similar to this. It was a case of considerable importance, and he wished to quote Mr. Justice Mathews as to the object of this Act. Mr. Vaughan said that was unnecessary. The preamble was sufficient to show the object of the Act, which was directed against the dangerous and unsightly sky-signs popular a few years ago. In his opinion, this structure was neither unsightly nor dangerous. Nor, in his opinion, was it a sky-sign in the popular acceptance of the term. He considered, therefore, that he would be going contrary to both the spirit and the provisions of the Act if he accepted the contentions of the County Council. He therefore dismissed the summons. On the application of Mr. Hall, the magistrate Mr. Vaughan, allowed £5 5s. costs. He refused to state a case for the opinion of the High Court, and this decision he adhered to when Mr. Chilvers repeated his application on Wednesday.

Sanitary State of Furnished House.—Abraham v. Power.—An action was tried in the Queen's Bench Division, on Tuesday, by Mr. Justice Wright and a jury, to recover damages for injuries suffered in consequence of the plaintiff having rented of the defendant a furnished house that was not in good sanitary condition. The plaintiff was a surveyor and estate agent, and the defendant was Major Power, of Leamington. In August, 1894, the plaintiff took of the defendant, for six months, the house, 38, St. George's-square, and entered into possession. Some time afterwards his wife and some of the children, servants, and other inmates of the house became unwell, suffering from sore throat and other mischiefs. These mischiefs were caused, according to plaintiff, by the drainage of the house not being in a good condition. For the defendant, it was said that he acquired the house in St. George's-square in July or August, 1890, and he spent £50 upon it in repairs and sanitary work. This was done through the Army and Navy Stores. He himself lived in the house from that time until 1893, and had no fault to find with the sanitary arrangements. The late Professor Stuart Poole lived in the house for six months, and afterwards it was occupied by Mr. Hobhouse, M.P., and the defendant received no complaint from either of them as to the condition of the premises. The case of the defendant, which was supported by the sanitary authorities of the parish, was that, although the most recent sanitary arrangements had not been adopted, yet the house was in a reasonably good sanitary condition, and safe for habitation. A good deal of evidence was given upon the one side and the other, by sanitary and medical experts, as to the condition of the house when it was let to the plaintiff in August last, and as to the probable cause of the illness that happened in it. The jury not being unanimous, were discharged without giving a verdict.

CHIPS.

The post of road surveyor for the Longtown Union, and sanitary inspector for the Low District, rendered vacant by the removal of Mr. Maxwell to Gainsborough, was filled at the last meeting of the Longtown District Council, held at Hallburn. There were 21 applicants for the situation, the choice falling on Mr. Murray, of Alstonby.

A stained-glass window, illustrating Mary weeping at the Tomb of Jesus, has just been erected in St. Catherine's aisle of Linlithgow parish church. The window is in memory of the late Mr. Robert Riddoch Glen, at one time town-clerk of Linlithgow.

The Local Government Board have sanctioned the application of the Middleton Corporation for powers to borrow a sum of £36,544 for the new sewage scheme. Sanction had already been given to the borrowing of upwards of £13,000, which had been paid to the Earl of Wilton for the site of the outfall works at Land's End, Rhodes.

The Duchess of Teck opened on Monday the new Children's Hospital at the corner of Church-street and Paddington-green. The hospital, which was illustrated in the Building News for August 17, 1894, by a perspective and plans, has been built by Messrs. Mark Patrick and Sons, of Westminster Bridge-road, from plans by Messrs. Stephen Salter and Adams, of Woburn-place. The cost has been £11,000.

On Saturday Major Marindin made an official inspection of the extensions of the Edinburgh Street Tramways Company system in Leith, just carried out from plans by and under the supervision of Mr. Carter, the company's engineer.

A fatal accident, the first which has occurred in connection with the extension of Marischal College Buildings, Aberdeen, occurred on Friday. William Reith (20), apprentice joiner, was engaged along with others removing the scaffolding from the central spire of the Mitchell Tower. A thin planking on which he stepped gave way, and he fell inside the tower, a distance of nearly 80ft. Death was instantaneous.

The Prince and Princess of Wales will open the new front building of the Royal Free Hospital, Gray's Inn-road, on Monday, July 22. The cost of the new buildings and of various other improvements which have been carried out during the past two years amounts to £30,000, towards which sum £24,000 has already been raised.

The executive committee of the Dean Payne Smith memorial resolved on Monday that the Dean and Chapter be asked to sanction the erection of a pulpit in the choir of Canterbury Cathedral, for which the committee will provide £500. The memorial fund, which is not yet closed, amounts at present to £927.

The Duchess of Teck will, on Tuesday next, at four o'clock, open the new building of the London Homœopathic Hospital in Great Ormond-street, which provides accommodation for 100 patients, and has cost £45,000.

The new chapel at Radley College was consecrated by the Bishop of Oxford on Saturday. The chapel has been erected from the designs of Mr. T. G. Jackson, A.R.A., at a cost of about £12,000. The building is 130ft. long, 32ft. wide, and 40ft. high to the wall plate. The roof is of oak, richly carved, and the floor is paved with squares of white and black Carrara marble. The reredos, a specimen of Early German wood-carving, has been transferred, together with the carved stalls, and most of the seats, from the old chapel. The east window is already fitted with stained glass, and it is hoped in time to fill the other windows in a similar manner. The organ will soon be erected in the western gallery.

WATER SUPPLY AND SANITARY MATTERS.

BILSTON WATERWORKS.—After receiving their supply of water from the corporation of Wolverhampton for a number of years, the inhabitants of Bilston some time ago decided upon providing waterworks of their own, and the memorial stone of the pumping-station at the Bratch, in the parish of Wombourn, was laid on Saturday. The local authority were fortunate in finding at the first boring a plentiful supply of water at the Bratch. A well has been sunk to a depth of 150ft., and the water is now running away at the rate of about 170,000 gallons every twenty-four hours. Parliamentary powers were obtained, and since then contracts have been given out for the erection of the pumping-station, the laying down of the pumping plant, and the provision of a reserve reservoir on a high piece of ground at Goldthorn Hill at Wolverhampton, whence the water will be distributed at Bilston. The floor-level of the reservoir is 342ft. above the overflow of the water in the well at the Bratch, 80ft. higher than the top of Hill-street, Bradley, which is the highest point in the township of Bilston, and 120ft. above the water-meters which will be placed in the Bilston market. The mains to carry the water from the Bratch to the reservoir will be about four miles in length, and the reservoir, which has been completed and is ready for the reception of water, consists of an underground chamber built of concrete, 116ft. long and 106ft. wide, with a water-level of 12ft. deep. The reservoir is covered by a series of concrete arches, 10ft. in span, which are supported by walls 2ft. thick, and archways to allow of the circulation of the water. It is provided to hold 750,000 gallons of water, or a day-and-a-half's supply to the inhabitants. The works at the Bratch consist of the well, engine-house, boiler-house, workshop, and pump-room. The buildings are being erected by Messrs. H. Wilcock and Co., of Wolverhampton, and have castellated parapets and gables. Externally they are of Ruabon red brick, with Hollington stone facings. The height to the top of the turret is 64ft., the chimney-stack will be 90ft. high, and will be built of brick, with stone coping, and will terminate with an ornamental iron railing. The contract for the machinery has been taken from the original contractor, and placed in the hands of Messrs. Thornewill and Warren, of Burton-on-Trent. Two large multitubular boilers, by Roots, will be provided, and Green's economisers will be used. Nearly £3,500 has been expended in sinking the well, and the reservoir has necessitated a similar outlay, while the engine-house and other buildings will cost about £6,000. To these sums will have to be added the expense of laying down the pipes from the Bratch to the reservoir, and the cost of the engines and other items. The engineer who has prepared the scheme is Mr. Baldwin Latham, of London, and it is being carried out under his supervision by Mr. C. N. Wilson, A.M.I.C.E., the engineer to the Bilston district council. The reservoir has been constructed by Mr. Henry Hill, of Maidenhead, and the well was sunk by Mr. John Hughes, of Dudley.

The Westmorland-road Presbyterian Church, Newcastle-on-Tyne, is about to be redecorated and fitted with the electric light. The electric-light installation is being put in by Messrs. R. J. Charleton and Co., and the painting and decorating has been intrusted to Mr. George G. Laidler. The work is being carried out from drawings and specifications prepared by Messrs. Badenoch and Bruce, architects, Pilgrim-street, Newcastle, who will also superintend the execution of the work.

At a recent meeting of the Harwich Harbour Conservancy Board Mr. Peter S. Bruff, of Ipswich, who for upwards of thirty years had acted as their engineer in designing and directing the works at Landguard Point, tendered his resignation of active work. Upon its acceptance by the Board, Mr. Bruff, who is in his 87th year, was appointed consulting engineer; and Mr. Thomas Miller, engineer to the Ipswich Dock Commission, who filled the position of assistant engineer to Mr. Bruff upon the original marine surveys and during the construction of the Landguard groyne and other harbour works, was appointed acting engineer.

The American School of Classical Studies at Athens is at work this season at Eretria, continuing the explorations begun there some years ago. The excavation of the theatre is almost complete, and a gymnasium has been uncovered. Three heads, three inscriptions, and some architectural fragments of interest have been exhumed.

Col. Hasted, R.E., Local Government Board Inspector, held an inquiry at Knaresborough on Tuesday as to an application made by the urban council for sanction to borrow £1,800 for works of additional water supply. The inspector was informed that the waterworks were purchased in 1872 for £12,000. Some opposition was raised to the scheme as being costly, without getting a better supply of water.

STAINED GLASS.

BERLIN.—Messrs. Campbell, Smith, and Co. have just completed the first of the series of stained-glass windows they are executing for the New Memorial Church, Berlin. The window as a whole suggests Triumph over Death, and contains subjects as follows:—Our Lord Triumphant, with the Resurrection Banner; St. Paul and St. Peter; with subjects in the lower lights of St. Paul with Eutychus, Our Lord Raising Jairus' Daughter, Our Lord Raising Lazarus, and Peter Raising Tabitha. There is also an early rendering of the Tree of Life, with the shields of the Emperor and Empress of Germany, and the Prince and Princess Henry of Prussia, and in the two smaller circles of tracery are Jonah Cast Out of the Whale, and the Ark Resting on Mount Ararat, symbolical of the Resurrection.

CHIPS.

Mr. Walter Jackson, for some years past the secretary to the Artisans', Labourers', and General Dwellings Company, Limited, died on Thursday in last week at his residence, Kempton, Prospect-hill, Walthamstow, in his 50th year.

The forty-ninth annual meeting of the Cambrian Archæological Association will be held at Launceston, by invitation of the Royal Institution of Cornwall, on Monday, Aug. 12, and the five following days.

Mr F. S. Button, borough engineer for Burnley, tendered his resignation on Friday to the highways and improvement committee, after a service of seven years.

Structural alterations and improvements have just been carried out at St. Mary Elms parish church, Ipswich. Mr. E. Fearnley Bisshopp, of that town, was the architect, and Mr. William Grayston, also of Ipswich, was the builder.

The national monument to Sir John Macdonald was unveiled in the Parliament grounds at Ottawa on Monday.

The new Welsh church at Penycae was opened on Sunday in last week. It seats 200 persons, and has cost £900.

At a meeting of the employés of the Oldbury District Council, held at the Central Fire Station, on Saturday, the Rev. H. McKean, on behalf of the men, presented a pair of handsome bronzes to Mr. H. Richardson, late surveyor, who is leaving Oldbury to take up a similar situation as surveyor to the Aston District Council.

On Monday afternoon week, July 15, Princess Henry of Battenberg will lay the foundation-stone of the new Free and Parochial Schools belonging to the parish church of St. John at Hackney.

A new Conservative club is about to be built at Millgate, near Rochdale. The architect is Mr. John Stott, of St. Anne's-on-Sea.

The forty-seventh annual general meeting of the Somerset Archæological Society will be held at Bath on Tuesday, the 23rd inst., and following days, under the presidency of Mr. H. Duncan Skrine.

One of the last official acts of Mr. Acland was the sanction of the purchase for South Kensington Museum of the large and valuable collection of woodwork of the Mediæval and Renaissance periods at the Peyer sale in Paris.

At the East Ham sewage pumping station on Monday morning, the chief engineer, Arthur Baker, and three other men, Fred. Mills, Walter Digby, and Robert Tarrant, who went down a well to clean the screen in front of the sewer pipes, were successively suffocated by the accumulation of foul gases, and a fifth, who was rescued in an insensible condition, has since succumbed.

A new wing is about to be added to the Devon and Exeter hospital, from plans by Mr. Cole, of that city. Messrs. Tree and Bolley, also of Exeter, have taken the contract at £6,445.

A new cemetery is about to be laid out at Willenhall. The work, which will include draining, forming roads, laying out and planting grounds, erecting mortuary, chapel, lodge, entrance gates, and boundary walls, is estimated to cost £5,500, and will be carried out from plans by Mr. B. Baker, surveyor to the district council.

The Percival Institute and Church Sunday school at St. Minver, Cornwall, were opened on Thursday in last week. The building is Gothic in style, and is built of local stone, with dressings of buff brick. Mr. W. T. Martyn Mear, M.S.A., of Wadebridge, was the architect, and Mr. T. Williams, also of Wadebridge, the builder. The cost was £500.

The opening of new offices for the Leek and Moorlands Building Society in Stockwell-street, Leek, which have been specially erected for the society from the designs of Mr. John T. Brealey, architect, Hanley and Rudyard, was celebrated on Wednesday week by a dinner at Highfield Hall, Leek, the residence of the chairman of the society.

STATUES, MEMORIALS, &c.

FRESHWATER, I.W.—As a memorial of the late Lord Tennyson, it has been decided to erect, in the place of the perishable and periodically-renewed framework which now serves as a landmark on Freshwater Down to passing vessels, a permanent beacon in the form of a monumental Iona cross. The design has been furnished by Mr. J. L. Pearson, R.A., who has taken into consideration the massiveness of structure and dignity of outline requisite in so exceptional a site, nearly 500ft. above the sea-level. A contract has been entered into with Messrs. Farmer and Brindley, of Westminster Bridge-road, for the execution of the monument in Cornish granite. Its total height will be 32ft., and the cross itself (24ft. in height) will be in two blocks, which are now being quarried. The Trinity House and Board of Trade have agreed to accept the monument as national property under the title of "The Tennyson Beacon," and to be responsible for its maintenance. Three-fourths of the estimated cost, £1,000, have been subscribed.

THE PASSMORE EDWARDS MEMORIAL FOUNTAIN, HAMMERSMITH.—A fountain to the memory of the late Mr. R. Passmore Edwards, one of the Library Commissioners, and a member of the vestry at Hammersmith, has been erected in the centre of the Broadway there, facing the vestry hall. It was unveiled yesterday by the donor, Mr. J. Passmore Edwards. The monument serves to record the opening of Ravenscourt Park to the public by the County Council of London, as the late Mr. Edwards was one of the prime movers in bringing about this great public improvement, now enjoyed by the whole of the district situate round the park. The fountain is executed in granite, and was designed by the architect of the Metropolitan Drinking Fountain and Cattle Trough Association.

A new Presbyterian church at Bromley, Kent, built at a cost of £8,000, was opened on Wednesday week.

The works of excavating for, and laying of new sewers are in progress throughout Stafford, under the direction of the borough surveyor, Mr. Blackshaw.

A new Primitive Methodist chapel, with schools attached, was opened on Friday in Ford-street, Coventry. The buildings have been erected by Mr. J. Worwood, of that city, from plans by Mr. John Wills, F.S.A., of Derby. The style of the buildings is Gothic, and the materials used are red bricks with Bath stone dressings. The chapel is 66ft. by 33ft., and seats 500 persons on the ground floor. At the rear is a schoolroom, 31ft. 6in. square, and four classrooms. The cost has been £2,000.

The Government of New Zealand recently sent a "timber expert" to this country to call attention in the proper quarter to the great value of the indigenous woods of that colony. The hauma is by far the lightest wood in the world, being only half the weight of cork. Another noticeable product is the hinau, an incombustible wood. The export timber trade of New Zealand ought to expand a good deal soon.

In celebration of the commencement of the erection of the Passmore Edwards Free Library at Truro, the mayor, Mr. Silvanus Trevail, gave a dinner to the men employed on the works and others at the Royal Hotel in that city on Monday week. The mayor presided, and the company numbered about thirty, including Aldermen E. G. Heard, Jennings, and Johns, Councillors Blenkinsop and Julian, Mr. R. Dobell (town clerk), and Messrs. M. Clemens and T. Battershill (the contractors).

The technical instruction and public library committee of York have arranged for the opening of the summer exhibition of pictures on Wednesday next, the 10th of July. They report that an interesting collection of works of art has been obtained, the following artists being among the intending exhibitors:—G. F. Watts, R.A., F. Goodall, R.A., W. F. Yeames, R.A., J. Sant, R.A., the late Henry Moore, R.A., Alex. Williams, R.H.A., David Murray, A.R.A., and Madame Henrietta Ronner, R.I.

The members of the Bristol Master Builders' Association had their annual excursion on Monday, when they made an incursion into West Somerset, selecting Bridgwater as their headquarters. The party left Bristol by an early train, and arriving at Bridgwater were conveyed in brakes by way of Spaxton to the grounds of Mr. E. J. Stanley, M.P., and thence to Quantock Farm, through a romantic district. Luncheon was partaken of at the farm, and then there was an excursion to Donsborough Hill and Camp, returning through Holford and and Stowey to Bridgwater. In the evening dinner was partaken of at the Clarence Hotel. The president was Mr. George Wilkins, and among the guests were the Mayor of Bridgwater, Mr. H. W. Pollard, contractor, of that town, and Mr. Stephen Ambrose, president of the Bath Master Builders' Association.

Our Office Table.

On Saturday, the 13th inst., the Society of Architects will hold its 10th ordinary meeting at Waltham Abbey, and as we hear that papers will be read by the Vicar of Waltham Abbey and by Mr. J. Arthur Reeve, whose work on Abbey Churches is well and favourably known, a successful as well as a pleasant meeting may be anticipated. This will be the last ordinary meeting of the current session, but it is probable that an additional meeting will be held in the field at an early date.

Nearly forty members of the literary and antiquarian Masonic body known as the "Quatuor Coronati" visited the City of Winchester on Saturday last, and inspected the buildings of the city, including the cathedral, the college, and the Hospital of St. Cross. Mr. F. A. Powell, F.R.I.B.A., and Mr. H. Lovegrove, A.R.I.B.A., accompanied the party from London, and they were met at Winchester by Mr. Stopher, a well-known local architect. The Dean of Winchester received the party at the cathedral, and ably explained the various portions of the building. The local arrangements generally were undertaken by Mr. Jacobs, a local antiquary, and the day closed with a dinner in the Guildhall.

Three fresh pictures have just been hung at the National Gallery. No. 1436, which is placed in No. 7 Room, is a "Vision of St. Eustace," by Vittore Pasono, an artist not previously represented in the collection. A full-length portrait of "Cardinal Richelieu," in his robes, by P. de Champaigne, has been hung on the staircase. It has been presented by Mr. C. Butler, and is numbered 1449. A Virgin and Child with Angels, by an unknown 15th-century painter of the Umbrian school, has been presented by Mr. J. R. Heseltine, and is hung on the east wall of the vestibule. The picture, which is numbered 1456, contains, in a predella medallion, portraits of our Lord, the Blessed Virgin, and St. John.

The tower of the parish church at Callington, Cornwall, was discovered to be on fire early on Tuesday morning, and only by strenuous efforts were the flames prevented from spreading to the nave. The church had, however, a narrow escape, as the oak screen dividing the tower from the nave was well alight by the time the hydrant was brought into action. Nothing could be done to extinguish the fire in the tower, which burnt itself out in less than three hours, destroying the splendid peal of six bells, cast by Pennington in 1777, and the clock erected by public subscription about thirty years ago. The tower, which is of granite, and about 100ft. in height, surmounted by four pinnacles, is seriously damaged, and the upper portion will have to be rebuilt. It is a source of satisfaction, however, that the church, which was built by Sir Nicholas de Assheton early in the 15th century, and contains a very fine organ and some ancient monumental tombs of great interest, has been saved. The fire, which broke out in the bell-chamber, is conjectured to have been due to a light left behind by some carpenters who had been engaged in restoring the woodwork in the bell-chamber on the previous day.

The collapse of several large buildings in New York city recently, resulting in the killing of a number of persons, has drawn public attention in America to the necessity for the education, examination, and registration of architects. In the case of one of the buildings referred to, a tenement house on Orchard-street, the jury held the owner, the contractor, and the building inspector to be criminally negligent in having used and allowed inferior material and workmanship. The plans also were found to be seriously defective, brick piers in the basement being loaded to the extent of 90 tons to the square foot, while the limit allowed by law was but eight tons to the foot. The architect of the building was practically unknown in the profession. The jury who investigated the circumstances in connection with the collapse of the building close their report as follows: "The most efficient check which could be placed upon practices of the kind which have led to this disaster would be the licensing of all architects, who should be required to undergo a thorough examination as to their qualications to practise an art upon which the lives of so many people depend." A fresh argument, if one were needed, in favour of the Architects' Registration Bill.

The second appeal of Mr. Neelon, contractor for the Toronto City buildings, from the decision of the lower courts, refusing him an injunction to restrain Mr. Lennox, the architect of the building, from interfering with or preventing him from carrying on the work on the building under his contract with the corporation, and to compel the defendants to deliver up possession of the works and for other relief, has been dismissed by the Canadian Court of Appeal, with costs against the plaintiff. The ground on which the trial judge refused the petition of the plaintiff was, as we mentioned in our issue of the 14th ult., p. 863, that under the contract the architect had power to dismiss the plaintiff without the consent of the court-house committee of the city council.

MEETINGS FOR THE ENSUING WEEK.

Monday.—Royal Institute of British Architects. Business Meeting. 8 p.m.

Saturday.—Society of Architects. Visit to Waltham Abbey, where addresses will be delivered by the Vicar, the Rev. F. B. Johnston, M.A., and J. A. Reeve. Train from Liverpool-street Station, 1.50 p.m.

The Society of Architects.

Founded 1884. Incorporated 1893.

The TENTH ORDINARY MEETING of the Society of Architects for the Session 1894-95 will be held on SATURDAY, July 13th, at WALTHAM ABBEY.

Members will be conducted round the Abbey by the Vicar, the Rev. F. B. JOHNSTON, M.A., and Mr J ARTHUR REEVE, who will deliver ADDRESSES on the architectural and antiquarian points of interest.

Members will leave Liverpool-street Station at 1.50 p m, and arrive at Waltham Cross at 2.26. Reduced second-class return fares (1s. 11d.) will be taken for those who notify the Secretary by the 10th inst.

ELLIS MARSLAND, Hon. Sec.

CHIPS.

The committee of the Birmingham and Midland Sanatorium adopted, on Monday, the report of the special sub-committee approving of the acceptance of the gift of the Royal Hotel, Sutton Coldfield, made by Colonel Wilkinson to be used as a sanatorium.

The foundation-stone of a new mission room was laid at Kettlebrook, Tamworth, last week. Mr. C. Starkey, is the honorary architect.

The Peterborough Cathedral Restoration Committee are issuing an appeal for £12,000 to repair the damage done by the storm in March, to secure the safefy of the west front, and to complete the repair of the transept in accordance with the recommendations of Mr. John L. Pearson, R.A. Lord Lilford has given £500, and about £1,500 has been promised.

During some excavations on Mr. Harry McCalmont's estate at Bishop's Wood, Hereford, the labourers came upon a large earthenware jar, not more than 6in. below the surface, filled with small Roman copper coins. On the following day a second vase, also full of similar coins, was found. The majority are of the reigns of Constantinus the Great and Constantius, A D. 338-360.

The reopening of St. Peter's Church, Rendcomb, Gloucestershire, after extensive additions, took place on St. Peter's day. Elaborate fittings in oak have been provided throughout, a new vestry and heating-chamber built, and the floors renewed. Mr. F. R. Kempson, F.R.I.B.A, of Cardiff and Hereford, is the architect, and Messrs. Collins and Godfrey, of Tewkesbury, the contractors.

Extensive additions are being made to the mansion of Mr. Cuthbert Quilter, M.P., at Bawdsey Ferry, on the coast of South Suffolk. Mr. Fred. Bennett, of St. Clement's, Ipswich, has taken the contract, which includes an extension of the main building and a new laundry.

The Royal Archæological Institute will meet at Scarborough, under the presidency of the Archbishop of York, from Tuesday, the 16th inst., to the 23rd. Prof. W. Boyd Dawkins, F.R.S., is president of the Antiquarian Section, and Mr. C. H. Read, F.S.A., is the vice-president. During the excursions visits will be made to Bridlington, Whitby, Beverley, Malton, Helmsley, Pickering, and Lastingham.

Mr. F. H. Tulloch, one of the inspectors of the Local Government Board, held an inquiry at the Church Sunday-school, Darton, near Leeds, on Thursday in last week, as to an application made by the Urban District Council for sanction to borrow £9,000 for the purpose of sewerage and sewage disposal. After hearing the evidence of the engineers, Messrs. Duncan and Pickard, C.E., Leeds, he visited the sites of the outfalls. The process of purification proposed to be adopted is the "carbonised refuse system," combining therewith the disposal of town's refuse with Jagger's patents.

Trade News.

WAGES MOVEMENTS.

Bradford.—The plumbers in Bradford and district came out on strike on Saturday, owing to a dispute with the Master Plumbers' Association, with regard to one of their by-laws governing the relationships of the masters and men. The point at issue is whether the men shall finish work at noon on Saturdays, or leave work in sufficient time to reach their respective shops at 12 o'clock. The masters contend that it would be unjust that they should have to pay for the time the men are walking to the shops, and, on the other hand, the men regard it as so much overtime without pay if they have to work right up to 12 o'clock, and then walk to the shops for their wages. Three months' notice was given by the masters of their intention to insist on the men working until noon, but the men declined to agree, and came out on strike on Saturday.

Glasgow.—At the annual conference of the Master Masons' Association of Glasgow and the Glasgow District of the United Operative Masons' Association of Scotland last week, it was agreed that the standard wages should be raised from 8½d. to 9d. per hour for the next twelve months, commencing from Monday, July 1st. Satisfaction was expressed by the members of the conference that the harmony which had existed for the last eleven years between the two associations remained unbroken. The working arrangement between the two associations was discussed and amended in various particulars.

Greenock.—The Greenock operative masons having asked for an increase of ½d. per hour on their wages, the masters have conceded the demand. The wages will now be 9d. per hour.

The Brine Baths Park at Droitwich, recently laid out for the convenience of the inhabitants and visitors to the baths, has been opened by Mr. John Corbett, of Impney, who has borne the whole of the expense. The park is situate in the heart of the town, on the main road from Birmingham to Worcester; but being in a valley, it is completely screened from the view of any houses or buildings save the towers of two churches. It is eleven acres in extent, is beautifully laid out with bedding plants, roses, &c., and contains lawns for tennis. There are numerous walks provided with rustic seats and chairs, and a carriage drive runs round the centre of the park. The laying-out of the ground was carried out by Mr. Davies, head gardener to Mr. Corbett.

The collection of modern pictures and drawings of the late Sir Robert Palmer Harding, of Wetherby-gardens, South Kensington, and properties from other sources, came under the hammer at Christie's on Saturday. The prices were, for the most part, disappointing, and the biddings very slow. Sir Frederic Leighton's important work, "Greek Girls Playing at Ball," one of the features of the Academy Exhibition of 1889, fetched only 700 guineas.

In order to carry out the proposal of a Protestant Episcopal pro-Cathedral in Belfast, a sum of £20,000 will be required in the purchase and clearing away of houses which stand on the intended site. When the promoters of the project approached the Corporation to ask for the Linen Hall site—far away the best in Belfast—the representatives of the Roman Catholic population also approached the Corporation with a similar request, and pledging themselves, if the site were granted, to erect a cathedral in memory of their late Bishop worthy of the city. The Corporation was thus compelled to refuse both appeals.

The manufacture of bricks, the staple industry of Sittingbourne and neighbourhood, is about to be developed by the acquisition by Messrs. Smeed, Dean, and Co., of 45 acres of brick earth at Highsted. The earth will be washed on the spot, and will be conveyed by means of pipes to the brick-fields belonging to the firm at Murston, a distance of two miles. The same firm have derived their supply of brick earth from Tong for some years, from whence the washed earth has been conveyed by pipes to their fields. In another part of the district it is contemplated to construct a small canal, to enable barges to reach the fields direct, and thus reduce the expense and the wear and tear of carting.

The tablet which has been erected in St. Nicholas Cathedral, Newcastle-on-Tyne, to the memory of Robert Roxby, the fisher poet (1767-1846) was unveiled on Friday. The cost of the memorial has been defrayed by public subscription. It has been placed on the wall at the west end of the cathedral, near the north door, and in the space containing already memorials of James Archbold, who was mayor of Newcastle in 1846, the late Ald. Joseph Forster, and Sir Leonard Greenwell. Mr. Robert Beall was the sculptor.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material.
Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.
Address:—
THE HAM HILL STONE COMPANY,
NORTON, STOKE-UNDER-HAM, SOMERSET.
London Agent:—
Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

WM. OLIVER & SONS,
MAHOGANY, WAINSCOT, WALNUT, TEAK, VENEER, and FANCYWOOD MERCHANTS,
120, BUNHILL ROW, LONDON, E.C.

The most extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

TENDERS.

*** Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender; it adds to the value of the information.

Burghfield.—For studios, for Mr. J. Dews, Burghfield. Mr. J. S. Dodd, Reading, architect:—

Goodchild	£237	0	0

Amersham.—For the erection of a villa residence near Amersham Station, for Mr. J. Sladen. Mr. Ernest Luckett, Aylesbury, architect:—

Sherwin, H. H., Waddesden	£920	0	0
Darlington, G., Amersham	900	0	0
Read, C. W., Watford	869	0	0
Brown, E. J., Watford	845	0	0
Grist, S., Bierton, Aylesbury	798	18	0
Wallis and Sons, Chesham	795	0	0
Grimsdale, Aylesbury	786	0	0
Siarey, Aylesbury	722	0	0

Chepstow.—For building a new boys' school, caretakers' house, offices, boundary walls, playground, &c., at Chepstow, for Chepstow Local Board:—

	A.	B.	C.	D.
Phillips, J., Chepstow	£2,043 12 0	£410 8 0	£721 12 0	£3,175 12 0

A.—School. B.—Cottage. C.—Drains, Fences, Offices, &c. D.—Total.

* Accepted, subject to the approval of the Education Department.

Colchester.—For proposed shop and premises at No. 4, Wyre-street, Colchester, for Mr. S. Balls, 40, Salisbury-road, Colchester:—

Near, Colchester	£1,130	0	0
West, E., Chelmsford	867	0	0
Dupont, F., Colchester	825	0	0
Beaumont, R., Lexden	816	0	0
Chambers, W., Colchester*	759	0	0

* Accepted.

Chelsea.—For the erection of a new choir vestry to St. Saviour's Church, Walton-place, Upper Chelsea, S.W. Messrs. E. Geldart and J. Randall Vining, of 89, Chancery-lane, W.C., joint architects:—

Foster and Dicksee	£330	0	0

Dartford.—For works of painting at the workhouse infirmary:—

Miller, P. (accepted)	£215	0	0

Deptford.—For new factory, Grove-street, Deptford, for Messrs. A. G. Scott and Co., Ltd. Messrs. Tolley and Son, 20, Budge-row, Cannon-street, E.C., architects. Quantities by Mr. F. H. A. Hardcastle, 5, Old Queen-street, Westminster, S.W.:—

	Scheme 1.	Scheme 2.	Scheme 3.
Waddington & Co.	£1,725 0 0	£3,493	£2,335 10 0
Gould and Brand	1,690 0 0	3,448	2,256 0 0
Bulled and Co.	1,690 0 0	3,420	2,208 0 0
Leney, H.	1,655 10 0	3,347	2,214 0 0
Falkner, J. W.	1,633 0 0	3,316	2,196 0 0
Carmichael, J.	1,615 0 0	3,290	2,162 0 0
Munday and Son	1,612 0 0	3,290	2,171 0 0

Dulverton.—For the construction of Perry-road, according to the plans and specifications of Mr. W. J. Willcox, Bath, Somerset County Surveyor:—

Facey, Taunton	£1,490	0	0
Gunn and Tarr, Dulverton	1,138	15	10
Smith, Minehead	1,275	0	0
Bond and Hitchcock, Taunton*	1,110	0	0

* Accepted.

[These tenders do not include the cost of two steel bridges, respectively of 40ft. and 50ft. span.]

Exeter.—For the erection of a new wing to the Devon and Exeter Hospital, for 75 beds, exclusive of heating, plumbing, according to plans prepared by Mr. Charles Cole, architect:—

Gillard, J. R., Exeter	£9,888	0	0
Trevena, W., Plymouth	9,496	0	0
Lapthorne and Co., Plymouth	8,000	0	0
Julian, J., Truro	7,983	0	0
Phillips, A. E., Woodbury	7,513	0	0
Setter Bros., Exeter	7,470	0	0
Westcott and Austin, Exeter	7,400	0	0
Stevens and Son, Exeter	6,997	0	0
Mudge, E., Exeter	6,957	0	0
Pratt, N., Clyst St. Mary	6,939	0	0
Gibson, W., Exeter	6,800	0	0
Ham and Passmore, Exeter	6,608	0	0
Herbert, G., Exeter	6,508	15	0
Tree and Bolley, Exeter (accepted)	6,445	0	0

Farnborough, Hants.—For new dining-room, &c., at Duns Cottage, for Col. Dorling. Mr. W. Trevena, Farnborough, architect:—

Smith, Farnborough	£530	0	0
Murrell. Blackwater	475	10	0
Kemp, Frimley	473	0	0
Mundy, Basingstoke (accepted)	435	0	0

THE FORTHCOMING A.A. GLOUCESTERSHIRE EXCURSION.

THE architectural interest of the Cheltenham district, which the Association proposes to visit this summer, hardly lies on the surface. Last week we gave a copy of the official programme. To-day some few notes from the district may be interesting. Cheltenham itself is not a place to throw the artist into transports; his natural desire would rather be, like that of Dromio of Syracuse about his supposed wife, to set it on fire and run from it by its own light. With Tewkesbury, Chastleton, and Broadway the case is, of course, very different. The days devoted to them, as well as to Winchcombe, Pershore, and Gloucester, will be well spent; but East Gloucestershire also contains a great many small places worth knowing, and little known. The villages do not show themselves from afar—as those, for instance, of Northamptonshire do. There is no hill, like the well-known one between Kettering and Thrapston, from which thirty towers and spires can be counted, all worth seeing. In the well-wooded west country the churches are often inconspicuous. They are widely scattered, and they are hidden amongst the valleys and the trees. Still more closely hidden are the other structures worth notice which cluster round them, so that a stranger may pass very near to things which he would gladly have examined, and yet may never suspect their existence. We may point out a few such things in the easternmost section of the district now about to be explored.

The very fine old house at Chastleton—well preserved and little altered, if it still remains as it was some fifteen years ago—is sure of its full share of attention. The adjoining church was also at that time extremely interesting. Its flooring tiles alone would have repaid the student for his walk; but if the project which was then talked of has since been executed, he may perhaps now find it difficult to distinguish the new ones from the old. Restoration need not be falsification, though it sometimes is so, and frequently attempts to be. One advantage which arises from these excursions of our future architects must surely be to sicken them with the word "restoration" altogether. The student who comes on a church which has only been repaired by some such harmless person as the village carpenter, rejoices as if he had found great spoil. But this does not happen every day. It is only those of us who are growing old who can realise what the interest of ancient work used to be. The glory has departed from most of it, and the parsons and the architects must divide the responsibility.

Still, it was not every restored church that was ruined. An architect here and there, like the late G. E. Street, had the knack of leaving an old building better worth looking at than he found it: not only because the new which he added had a value of its own, but because he brought the old to light in cases where it had long been hidden. Thus, at Shipton-under-Wychwood, a few miles from Chastleton in the direction of Oxford, there may be seen, since Mr. Street restored the church some 35 years ago, a good stone pulpit, which, it is said, had been boxed up for nearly a century inside the old-fashioned "three-decker." It is of Perpendicular date, polygonal on plan, with a panelled lower stage, curving over to carry the floor; and a parapet or inclosure above, with square buttresses set anglewise at each corner. The buttresses end in gabled and crocketed pinnacles. Between them, on each face of the polygon, is a sunk tracery-panel of two lights, with a crocketed ogee head. The parapet is finished with a moulded coping.

The archæologist who scorns such modern things as these has not far to go for something older. Near Long Compton—three miles or so from Chastleton in a north-easterly direction—he will find the ancient circle called the Rollright Stones, and he may try whether the local belief is correct, that it is impossible to count them twice alike. There are from 90 to 100 fragments embedded in the soil; but being much split and cracked, what looks like one stone from, say, the north side of it, may be reckoned as two or three when it is seen from the south. In a field not far off are several much taller blocks, called the "Whispering Knights." The highest of all, according to local tradition, would have been King of England, if he could only have seen Long Compton village from where he stands. Unfortunately, it is out of sight from this point, though it comes into view a few steps further on. Through this circumstance—as well as through the additional one, that Long Compton had probably not yet come into existence—the unfortunate knight was unable to discern it, and the consequence was that he and his companions were turned into stone. There is a large barrow not far off, and other remains, so that, altogether, the neighbourhood seems to have been a busy one in prehistoric times. At Swell Wold farm, about half-way between Chastleton and Cheltenham, great numbers of neolithic weapons have been found—arrow-heads, spear-heads, scrapers, and the like—often of very delicate workmanship, and little injured by time or accident.

The railway from Cheltenham to Banbury, which crosses the West Midland at Chipping Norton Junction, runs for three miles—namely, from Bourton-on-the-Water to Stow—almost by the side of the Great Roman Fossway, which ended at Bath. Late Roman remains are common here: small coins of Valens, Valentinian, Constantius, and Constantine the Great are often met with. There is an old camp at Bourton, and adjoining it a ground called the "Bury Field," from the number of skeletons which have been dug up there. The gravel soil has kept many of them in wonderfully good preservation; even the small bones of the fingers and toes are often uninjured, and the teeth are remarkable for their soundness. Bourton was formerly a very pretty village, with the Windrush brook flowing rapidly through on its way to the Thames, and four or five bridges across it to connect the houses on one side with those on the other. Before railways came, there was not a brick to be seen in Bourton. The houses were stone-walled and stone-slated. The old Gothic church had, as it still has, one of the oddest and ugliest of quasi-Classic towers, put up about A.D. 1700, with pinnacles and a leaden dome. Internally, there were plaster ceilings and other Italian details, the result, apparently, of a desperate effort to copy Sir Christopher Wren, and to follow what then was the fashion. The church has in recent years been restored by Mr. T. G. Jackson.

Stow-on-the-Wold, the next station on the Cheltenham and Banbury line, has some interesting fragments of domestic architecture. Amongst them is an Early Gothic doorway. The old hoods to the house entrances, too, are noticeable. They consist of projecting flagstones, moulded round the edge, and boldly corbelled out. There is a curious pargetted pattern—though pargetting is by no means common in this rubble district—on a building near the top of the town. Stow is three miles from the Adlestrop station on the West Midland, and very near to this is the disused church of Oddington, with a low Perpendicular tower in the position of a transept. This is not an unusual arrangement hereabouts. The old distemper decorations, the lining-out of the wall-plaster, with suggestions of joints, may still be seen inside, if damp and neglect have not recently destroyed them. Half a mile across the meadows from Oddington is the village of Daylesford, once the residence of Warren Hastings. Its little cruciform church was one of Mr. Pearson's early works. It has a square spire, with a marked *entasis*. Bledington is the village adjoining Chipping Norton Junction, two or three miles along the line from Adlestrop. Its church, considerably out of repair, and full of the handiwork of many periods, including the period of churchwardens, used to be a very interesting one. We hope it is so still; but it has now, we believe, been restored. There was a large distemper figure of St. Christopher on the north wall. There were some good Perpendicular bench-ends, and other old woodwork, with traces of colour on it. The glory of the building, however, was its stained glass. Much of it was damaged and displaced, but some of the upper windows were fairly perfect. They were chiefly memorials of departed parishioners; one, with kneeling figures, commemorated Thomas Andrews and Agnes, his wife, who departed this life in 1470.

Near Bledington is Icomb, where there is a small church with a saddleback tower, and a group of three lancets—well treated internally—in the chancel gable. There is a similar group in the east end of Wick Rissington Church, about a mile off; but here the external treatment of the lancets is odd in the extreme. They have lozenge-shaped panels over them, and the dripstones are contorted round the arches and the panels in a way which is more singular than beautiful. At Little Rissington are the remains of a bell-cot over the chancel arch. Lower Slaughter, on the outer side of Bourton, used to have a saddleback tower. It was pulled down some 20 years ago to substitute a spire of the "pretty-pretty" type, quite out of place in the neighbourhood. Upper Slaughter, a mile beyond, has much interesting detail of the 12th century or "Transitional" date. Besides the church, there are some houses worth notice there. All these villages, compared with Chastleton, are more or less in the direction of Cheltenham. Near that town is Charlton Abbots, where there is one of the smallest churches in the county, and a fine mullioned and gabled house, now attached to a farm. The larger rooms, not very many years ago, retained their carved and panelled wainscot lining, of great beauty. But it did not please the bucolic mind, and it was torn out and cast away, that there might be a dining-room papered and corniced in the "modern" style. A little taste, like a little learning, "is a dangerous thing."

The last skirmish in the Civil War of Cromwell's time took place at Oddington, near Adlestrop. There was also fighting at Slaughter, though the name of the village does not seem to have resulted from any battle of that period. There is a tradition that after some great fight, nobody knows when, a man in armour rode into Bourton-on-the-Water, still sitting upright on his horse, though his head had been cut off. Memories of the Danes, too, linger in the neighbourhood. A farm called "Woeful Lake" is said to get its title from the tinge of blood in the water there after some great encounter. Not far from it is another which bears, from olden times, the name of "Starve-all," suggesting, as also does a third called "Empty Cupboard," that agricultural distress prevailed in much earlier centuries than the 19th. These uninviting titles, however, belong to the hills. There the oolite is close to the surface, the ground is shallow, the trees are few, and the fields have dry (i.e., mortarless) rubble walls instead of hedges. In the valleys the case is very different.

Each has its trout stream, bordered by rich meadows with abundant foliage. We are in Shakespeare's country, for Stratford is only sixteen miles from Chastleton, as the crow flies. It is not only Master Shallow, "in the county of Gloucester, justice of the peace and Coram," who belongs to the district and speaks its dialect—it is really a Gloucestershire valley, and no Bohemian one, that forms the back ground to the comedy and poetry of the "Winter's Tale." The clown and the shepherd, Mopsa and Dorcas, converse in the language of the Cotswolds. Eyes still living have seen Autolycus, disguised, it may be, as a morris dancer, it may be as a "Cheap Jack," and even Perdita herself—"too noble for this place," though looked on for the moment as only a "queen of curds and cream"—may have trodden the paths by the Windrush and the Evenlode.

STRIKING CENTRES OF ARCHES.

THE oldest, and probably the simplest, although not by any means the most accurate, method of striking, easing, or lowering the timber centring of arched bridges consists in the employment of wedges. These are driven in under certain parts of the framework in positions which readily allow of their being driven out again when the arch is "turned," the stonework or brickwork thoroughly well set, and the time arrived for gently lowering the whole superstructure down to its permanent bearings. The whole operation was a most delicate one, and demanded a very accurate and precise adjustment of all the parts of the centring to carry it out successfully. Great care and skill were required on the part of all those engaged on the work, from the superintending architect or engineer down to the men who loosened or drove out the wedges with their hammers and beetles. In striking the centres of Waterloo Bridge pendulum beetles were used, which were swung back to give them a sufficient amount of impetus, and then delivered their blows very much after the fashion of the ancient battering rams. Obviously the great object to be aimed at is that the whole of the arch should be lowered at exactly the same moment of time, and to exactly the same amount. It is just here where the principle of the arch comes into play. A partial or small irregular settlement, which would be productive of no permanent damage to an ordinary trussed roof or horizontal girder, might be fatal to an arched rib of metal, rings of brickwork, or voussoirs of stone. Moreover, when the arch is constructed of either of the latter two materials, the rebuilding of it is a troublesome and expensive work. It is true that an arched rib of either iron or steel would not be affected to the same extent, unless the settlement were one of magnitude, as those of stone or brick. This immunity is due to the fact that although the arch of metal depends upon the same principle as all those of a different material, yet iron and steel are both capable of withstanding tensile stresses to which a threatened collapse would expose them.

It is not always possible, in building arches of any material, to obtain supports for the centring except at or near the points of springing—that is, at the piers—if the bridge consists of several independent spans, or at the abutments if there should be only a single span. This led, as the easiest way out of the difficulty when the thoroughfare had to be kept clear under the bridge during the whole time of its construction, to supporting the struts—which were placed in an inclined position, abutting against the horizontal chord of the centre—upon the corbels, footing courses, or any projections which the masonry or brickwork might offer. The centres of the bridge already quoted were supported in this manner; the "striking" plates, as they are termed, were longitudinal, and were carried upon struts of timber, which rested upon the several steps or offsets of the stone piers and abutments. This mode of supporting centres is a vicious one, and it is worth noting that most of the centres designed by so distinguished an architect as Perronet were conspicuous for this grave defect. In spite of the best precautions observed, and all the care taken to avoid unequal and insure isochronous settlement of an entire arch, the two conditions are rarely perfectly attained. It is impossible when the ordinary wedges are used, unless the span of the arch is comparatively small, to insure that they shall be "struck" all in one piece, so to speak. Some of the wedges must have less pressure on them than others, some have not perhaps been originally driven home so tight and closely as others, and again some may have—as they undoubtedly do—become loosened and slack during the progress of the works. They do not, therefore, all require the same amount of violence to ease them, and this want of uniformity in the force required renders the structure liable to shocks of a very uncertain and sometimes of a dangerous character. Before quitting this part of our subject, it should be stated that occasionally it becomes advisable under exceptional circumstances to ease—not to "strike," in the full meaning of the term—the centres of an arch at some particular point and not at others. A judicious lowering at the right moment of this description will frequently do a great deal to preserve the true lines of an arch, and prevent any twisting or unevenness in its soffit, which is very objectionable, particularly in a skew arch built with spiral courses.

FIG. 1.

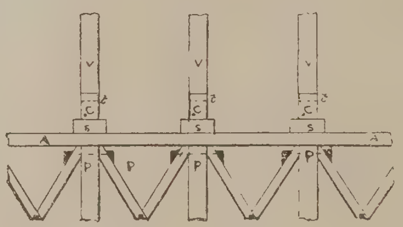

FIG. 2

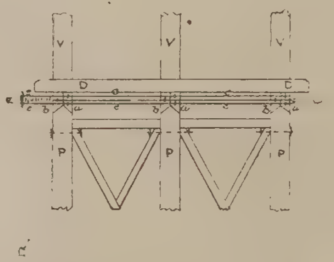

FIG. 3.

FIG. 4.

FIG. 5.

A very ingenious plan for insuring the accurate and gradual easing of the centres of an arch was adopted at the building of the bridge of Austerlitz in Paris. The general arrangement of the whole method is represented in Fig. 1, in which P P is a strong timber platform, strutted and braced together in the ordinary manner, and carrying at the top, on the pillars P P P, a horizontal balk or stringer, A—A. The joists and planking framed in between the stringers are not shown in the figure, as they are not needed for further illustration. Upon the horizontal balk exactly over the pillars are fixed circular sockets or discs, S S, and to them are solidly attached the plate iron cylinders C C C, rather more than 1ft. in diameter. Each of these is filled with clean, sharp, pure, dry sand, up to the height shown at *t*, and upon the sand rests the foot of the upright posts constituting part of the framing of the centre. The joint between the foot or end of each upright post, and the interior of each cylinder, is made good by a quick-setting cement. At a short distance above the base of the cylinders there are four holes bored at the same height round the periphery, having a diameter of $\frac{7}{8}$in These holes are plugged with corks during the building of the bridge. When the centres are to be struck, the corks are removed, and the sand gently, uniformly, and very gradually flows out, causing a proportionally slow and easy lowering of the whole superstructure. An advantage of this method is that, should it become necessary to suspend or arrest the striking operation at any moment, it can be at once readily accomplished by the re-insertion of the corks. No doubt the same operation could be also stopped in instances in which ordinary wedges were used, but not to any degree of accuracy and precision approaching that insured by the more delicate sand process.

Instead of placing the wedges in positions which are not readily accessible, it has been proposed to place them as represented in Fig. 2, and effect their lowering by means of a pair of screws working in opposite directions, parallel to one another. The arrangement can be applied to any principle or form of centre, and we have shown it in Fig. 2 adapted to the example in Fig. 1. Upon the top of the uprights P P P, which are themselves cut to the form of a wedge, are fastened a pair of wedges, *a b*, those figured *a* facing in one direction, and those figured *b* in another. The wedges *a* are kept in position by a pair of bars, *c c*, which are connected to the head of a screw at E and to the wedges by the cleats shown in Fig. 2. A third bar or rod, or any other convenient section of iron, is similarly attached to the wedges *b*, and terminates also in a screw at *d*, from which it is evident that the two former bars *c c* are at liberty to slide freely over the wedges *b*, and the bar *d*, placed between the two other bars *c c*, can also slide along the wedges *a a*. On the wedges is placed the cross-beam D, or striking-plate, and upon it the vertical members V V V of the centre, as shown in Fig. 1. During the building of the arch the screws will be tightened until the opposite wedges are in close contact. It is evident that if now the screws be slackened, the bars *c c*, which are attached to one of them, will move the wedges *a a* in one direction, and the bar *d*, which is attached to the other, will move the wedges *b b* in the contrary direction. They will be thus separated from one another, will slide down the chamfered shoulders of the uprights, carrying the striking-plate with them, and will very gently and gradually allow the whole centre to subside. There are a double set of bars or rods, one on each side of the wedges, as shown on plan in Fig. 4. A longitudinal section is given in Fig. 3, and a cross-section in Fig. 5. Manual labour is all that is required to manipulate the screws, so that a uniform and simultaneous lowering of the centres can be accomplished with facility, and in cases where necessary, the operation can be suspended at any one time and renewed at another. There is no doubt that either of the two methods described and illustrated allows of the workman having a command over the whole striking of the centres of a bridge, which he cannot have under the old system of the employment of a large number of wedges, which depend altogether, in the first place, for their adjustment, to a succession of violent blows; and in the second, to their final position, to the same rough and uncertain agency. Both the sand process and that subsequently described are inexpensive, and the whole operation is conducted in a quiet, scientific manner, which contrasts favourably with the violence which it was absolutely indispensable to have resort to when centres and the striking of them were designed and built half a century ago.

Under the old "contract system," which had a widely different signification to that which pertains to the same phrase of the present day, the engineer or architect had little or nothing to do with the means employed by the contractor to execute the work included in his contract. For the time being the contractor was master of the situation, and so long as he carried out the works intrusted to him in a proper manner, and in accordance with the provisions of the specification and the contract agreement, he was at perfect liberty to employ any *modus operandi*—any means to the end—that he considered best for his own interests. No doubt, if any of his means to the end—that is, his temporary works—were of a character likely to be dangerous to the safety of the public, the architect or engineer would point it out to him, and request him to either secure or remove it; but there their power ended. An instance came under our own experience: it was before the days of local inspectors, when a contractor put up a temporary wall to carry half the weight of a gantry, the other half, or other pair of wheels, being supported by staging. There is no question but that the wall was too weak even for a temporary structure, and so thought the superintending engineer. He accordingly ordered the contractor to strengthen it or pull it down, which he declined to do, and in justification observed that by the terms of his contract he was liable for all "accidents, injuries, and damages to persons or property during the construction of the works," and that he had accepted the risk. There was no more to be said, and the wall did perform its duty satisfactorily until the termination of the contract. It is quite certain that we should never have had such men as Brassey and others, who made the name and reputation of the English contractor famous throughout the world, had there not been conceded to them a tacitly admitted *carte blanche* respecting the means they might employ in carrying out their gigantic undertakings.

NOTES FROM EDINBURGH.

BUILDING operations, though somewhat retarded by the unusually long and severe frost, have not suffered from the weather since, which has been unusually fine. Plasterers have had a slight advance, and the mason's wage is from 9d. to 10d. per hour. The transactions of the Dean of Guild Court do not indicate that much is doing in the best class of dwellings; but the increase in tenements for the labouring and middle classes is steady, and there has been the usual amount of alterations in the last six months. The Caledonian Railway Station, which is all but completed, looks out on the western extremity of Prince's-street, with imposing magnitude; but the alterations of the east end, for which preparations have been making for some time, will eclipse it in many ways, and some people of lively imagination think that the new hotel will ruin the aspect of this part of Princes-street by throwing the Register Office, Post-Office building, and even the Calton Hill into the shade.

The North Bridge, so long associated with the New Town, must go to make convenient room for the increasing railway traffic, though as sound as when it was built 150 years ago. In room of the fairly conspicuous portion of the street at the north-west extremity, another and a much more ornate building, still loftier, will take its place, having the offices of the N.B.R. company below street-level, and a hotel which will, by all accounts, surpass all the other large hotels of the city, both in the extent and splendour of its accommodation. The cost of the new bridge, estimated at £80,000, is to be defrayed partly by the railway company to the extent of about £30,000—not considered a very fair or good bargain for the city, which, at great cost, widened the bridge about twenty years ago. It is, however, a small figure compared with the large expenditure of the company on the station, offices, and hotel, only many think that this is not the last or least of the sacrifices which will be made to satisfy the contingent necessities of the N.B.R. traffic. Already a scheme for the reconstruction of North Bridge-street on the south, to match the wider bridge, has been roughly estimated, and if it can be made to yield anything like a reasonable return, it would doubtless be a desirable improvement.

Another and more necessary improvement scheme, and one which appears to be in a fair way to be carried out before long, is the reconstruction of the Municipal Building. Since 1886, when competitive designs were invited for new buildings on the present site without any practical results, some slight improvements have been made in the interior arrangement, and old adjoining property on the west side of Exchange-square has been purchased by the authorities with a view to future extension. The Lord Dean of Guild and the city architect have been considering the case, and have succeeded in putting into shape a plan by which, at a cost less than that of any of the many competitive designs, sufficiently good accommodation can be provided. The principal details, with plans and elevations, are submitted for private circulation in a volume issued by the city council. This contains also a history of the city municipal offices and their migration from the earliest date till they found a decent habitation in Exchange-square. This is compiled from ancient records, and is illustrated by views of ancient buildings, and is probably the fullest account existing of the very curious and generally inadequate accommodation provided for the transaction of the city affairs. Whilst the main object of the scheme has been the providing of more ample and necessary additional accommodation, the architectural aspect of the whole has not been neglected. The new wing, forming the west side of the square, gives office accommodation on the ground floor, and a good council-chamber, about twice the size of the present one, above. The style of the High-street front, which is Palladian, with pilasters and large pediment in the centre of the south front, is retained for the Square. The north elevation, which is conspicuous in Cockburn-street by reason only of its great altitude, has been substantially built, and is retained, but with alterations externally which alter it greatly for the better, the uniform monotony of the fenestration being broken up, and a tower erected at the eastern extremity. The Classical features of this elevation are not so pronounced as to be inconsistent with the altitude and style of the surrounding buildings of Cockburn-street, and probably nothing better could be devised along with economical retention of the existing walls. The cost is estimated at £50,000.

The Prudential Assurance Company have obtained a warrant to take down the London Hotel, a large edifice at the south-east corner of St. Austin-square. The architect for the new building is Mr. Waterhouse, R.A., and the work is proposed to have an exterior carried out in terracotta details. If so, it is to be hoped that the colour will be something more consistent with the grey stone around it than the usual brick-red. The tenements of this square have been in great parts altered from the original design, which was, like that of Prince's-street, very commonplace, with exception of the Royal Bank. There are fine specimens of Classic architecture in the Scottish Widows' office and the British Linen Bank, and there is some regret that the new addition should be erected in other material than stone. But as the plans have not yet passed through the Dean of Guild Court, it is premature to criticise, and the name of the architect is a kind of guarantee that the interests of the city architecture will be safe enough.

The co-operative system has been a potent factor in the matter of building operations, and has been making advances which have been making themselves appreciated as one after another of their large buildings are erected. Generally they are conspicuous, not only by reason of their magnitude, but also by their respectable appearance as additions to the City. The Chancellor Flour Mills is an effective sample of massive and well-ordered design; and the new Stores at Tollcross, costing £80,000, are a great improvement in that quarter. These are the property of the St. Cuthbert Association, which has also some rather ornate buildings in Fountainbridge and Spittal-street.

The Northern District Association is also flourishing, and has recently purchased for £14,000 the small property of Patriot Hall, where they are erecting a large bakery, and stores for that department, with all modern improvements. The edifice is in brick with hollow walls, lined inside with glazed white bricks, and stands behind the street, where there is ample and convenient building space for the erection of the shops and stores, at present inconveniently housed in St. Stephen-street.

The installation of the electric-light has at last been carried out, and the number of electrical engineers is already vastly multiplied. The light has not yet found its way into the churches or any public halls, where, in the interest of ventilation, it would be a very great improvement; but many large business premises have adopted it. The consumption of gas, however, is not diminishing, gas-engines and gas-stoves being more and more appreciated. The price of illuminating gas is still high, being 3s. 4d. per 1,000c.ft.

The new premises of Jenner and Co., in Prince's-street and St. David-street, are all but completed, and have been cleared of the hoarding and scaffolding for some weeks. They form what may well be described as the most ornate building in the city, always excepting the Scott Monument, which still holds its own. Dilettante critics, whose ideal of fine architecture is formed on the Parthenon and the proportions of the Early Renaissance of modern Athens, have dubbed the new addition "horrid," and have included in the criticism the new hotel, which apparently is in the same florid style; but there is much more to approve in the addition than such critics can find to censure. The whole is, at least, a splendid specimen of masonry, in one of the best and most beautiful freestones, and the skill and perfection with which walls so cumbered with ornamental detail have been completed, is an enduring monument which speaks for itself. The large amount left to be expended in the ornamental on this edifice places the architect nowadays at some disadvantage, as the chances of serving any apprenticeship in architecture if such costly erections should become general are few and far between. The most conspicuous defect is the lack of unity in the arrangement of details, and, indeed, of artistic design. The ornament follows, as it ought to do, the lines of the flooring and the window openings; but the building at a distance, where detail has disappeared, is as commonplace as any in the street, and even more so than its neighbours. The pillar and pilaster decoration is overcrowded on the Princes-street and corner, leaving great portions of the long St. David-street frontage so plain as to give it the aspect of a different edifice altogether; and a more equable distribution of these details, and some variety in the windows, would have secured a more consistent and imposing whole. The pillars are heavy, and the podium too slender, and weaker in appearance still by being carved over the surface, and generally the surface-carving is of the vapid Elizabethan kind, suggesting nothing beautiful in earth or sea or sky. Heraldic without the heraldry, and put on without special need where-ever the plain surface is left, or as if, as Mr. Gladstone once put it, it were not decent to leave a square foot of surface naked. The projecting stairs on the St. David-street side are bald, and finish with solid and clumsy square tops; and there is a very original form of turret crowning the corner, compounded of chimneys, Tudor pinnacles, flying buttresses, niches, and figures, which is intended to be seen to advantage only on the front. These eccentricities, however, are pardonable from their novelty, and the edifice is erected as a sample of street architecture—not to edify the public or improve the public taste, but to make them gape and stare at the grand advertisement. The interior detail is much more consistent. No expense has been spared in the grand saloon, which is, both in material, decoration, and convenient arrangement, far the finest in the city.

CLASSIC DETAILS AND THEIR APPLICATION.[*]

By G. A. T. MIDDLETON.

III.—CLASSIC TIMES: THE CORINTHIAN ORDER.

ALTHOUGH the Corinthian Order differs from the Ionic in little else than the capital, its origin is apparently distinct, and can be much more readily traced. In the cases in the Konyunjik Galleries in the British Museum there are several carved ivory ornaments of distinctly

proto-Corinthian type, brought from Assyria by Sir Henry Layard, and which may be approximately ascribed to 800 B.C.; but further back than this there is the simple palm-leaf capital of Egypt, of which an example in the British Museum is ascribed to the time of Rameses II., or about 1333 B.C., and earlier than this again is the bell-capital, with the palm-leaf painted on it, which can be traced to the earliest Theban times, or, at any rate, to the erection of the palace at Luxor, about 1500 B.C. These, however, must not be confounded with the capitals of distinctly Corinthian type, which are found at Philæ and in most of the other buildings of Ptolemaic Egypt, for the first Ptolemy having been a general under Alexander the Great, his date, and that of his successors, is long subsequent to the building epoch in Greece.

So far as one can judge from the examples left to us, the order seems to have been employed by the Greeks entirely in a subsidiary sense, for we may put aside consideration of the huge Temple of Jupiter Olympus at Athens, the date of which is very uncertain, while most authorities consider

(Now in the British Museum.)

it to have been essentially, if not entirely, Roman. Thus, at the Tholos at Epidauros, where is the earliest known example, ascribed generally to the time of Pisistratus, or about 560 B.C., the Corinthian Order is confined to the inner peristyle, the exterior being Doric; while in the Temple of Apollo Epicurius at Barsæ, at Phigaleia, built by Ictinus about 430 B.C., there is only one Corinthian column, the internal order being Ionic, and the external Doric; and at the Temple of Diana, at Ephesus, there could have been but few, though the exact number is controverted, and, strangely, enough, the example in the British Museum is elliptical on plan, instead of being circular. As to the two better-known and later examples, those of the Choragic Monument of Lysicrates and of the Tower of the Winds, both at Athens, the buildings to which they are applied are themselves but small works, little gems upon which great elaboration of detail might be indulged.

Just as with the Doric and the Ionic, so the Corinthian capital, when it first appears in Greece, is already fully formed. Early as is the work at Epidauros, the capital from thence is as beautiful and as perfect in conception and in execution as are any of the later examples. The fern-leaf of Egypt has given place to the sharply-defined acanthus, with long-drawn, simple lines, deep under-cutting, and absolute precision of workmanship so characteristic of Grecian work, and so unapproached by that of any other people before or since; and, it may be said, so impossible of attainment in any other material than the finest marble. So, too, we find the tendril volute and the lily-bud, springing out from the bell of the capital which they are there to adorn, having no constructional function whatever to perform.

It will be evident, even from the photograph of a fragment which accompanies this, that the capital at Ephesus was essentially similar to that at Epidauros in the arrangement of the acanthus leaves, the volutes, and the caulicolæ (or smaller tendrils), and this in spite of the difference of place already mentioned; but in the Choragic Monument of Lysicrates there are several noticeable variations. In place of the lowest range of acanthus leaves there is a band of vertically-rising water leaves of the most severe and simple form, and the acanthus leaves of the upper tier are crowded together, each alternate one standing out in front of its two neighbours, and the junction being hidden by pateræ; while the lily of Epidauros is replaced by the anthemion.

As to the capital at the Tower of the Winds, it scarcely deserves to be called Corinthian at all, for it varies so greatly from other examples. The volutes are here absent altogether, the ornamentation consisting only of a tier of acanthus, surmounted by a tier of water leaves; but, as in all other examples, the design and execution are superb.

With its adoption by the Romans a complete change came over the Corinthian Order; and, in fact, few things show more markedly the contrast between the peoples of Greece and Rome than does the treatment of the Orders. The Doric, loved by the Greeks, was too subtle and severe for Roman taste, which was, however, suited admirably by the elaborate Corinthian. Hitherto treated as a very choice bit of detail to be introduced with care and restraint and kept subordinate to a severer whole, it was now adopted with enthusiasm, and made to do duty everywhere, whether intrinsically suited to its position or not. It was subordinate now only in the sense of being used as the topmost of the three Orders when they were superimposed; but most of the greater works, whether temples, baths, or triumphal arches, were of the Corinthian order alone, either in its pure form or in its variant, the Composite.

Used thus largely in great buildings and in small alike, plenty of complete examples exist, the proportions of which can be determined; and it will be seen by the following tables that, governed by the greater height of the capital, a greater proportional height of column to its diameter was necessitated than with either of the other Orders, while the taper was less:—

Examples.	Diameters in Height.	Entablature in Terms of Diam.	Inter-Columniation.	Height of Capital in Terms of Diam.	Upper Diam. in Terms of Lower Diam.
Corinthian.					
Pantheon portico	9·804	2·317	2·092	1·175	·855
Jupiter Tonans...........	10·241	2·069	1·558	1·167	·867
Jupiter Stator	9·820	2·536	1·575	1·08	·891
Arch of Constantine ..	9·661	2·388	—	1·095	·882
Composite.					
Arch of Titus	10·662	2·533	—	1·287	·887
Arch of Septimus Severus	8·260	2·316	—	1·144	·882

The three examples illustrated herewith may be considered to be fairly typical, though great liberties were often taken with the design, especially in later times, figures of animals (the horse, for instance, in the Temple of Mars Ultor) and natural foliage being occasionally introduced. Good workmanship was still the rule, but the simple lines of Grecian work were replaced by more voluptuous curves, and a greater multiplicity of members. The acanthus suffers in particular, its sharply-defined points and arrises being replaced by a form of leaf which is of a rounded character, and which is not always guiltless of a surface-wave, such as a line drawing in elevation can scarcely show.

Owing to their great height from the ground, it was evidently right to leave the Corinthian capitals of the Colosseum with quite plain water-leaves, or merely outline suggestions of the acanthus, and similarly it was right to give greater details to the capitals of the Pantheon portico, in which instance, it may be remarked, the columns were left unfluted, and the richly-carved capitals gained greatly in value and appropriateness in consequence.

Another point to which attention may be drawn is the fact of the ornamentation being designed by the Romans for weight-carrying, the angle volutes being strong in form, and supported by the acanthus foliage underneath; and it seems to have been the desire to obtain greater strength which prompted the combination of the Ionic and Corinthian capitals in the Composite. Strangely enough, though, in the earliest known example of the Composite capital, that of the Arch of Titus, it was employed as an applied order only, with no constructional value, the opening being spanned by an arch!

Clumsy in its very conception, and possessed of no intrinsic beauty of line, this form of capital depended largely for its effect upon the wealth of surface-carving with which it was enriched, and which was often itself of a character which compares very unfavourably indeed with the clear-cut and entirely conventional forms of Greece. Never used very largely, even by the Romans, and never developed to any high degree of excellence, the Composite capital may now be regarded as rather an archæological curiosity than as a form to be largely used, the opportunities for its correct application being extremely rare.

"BUILDING NEWS" DESIGNING CLUB.

A RIVERSIDE BUNGALOW.

THIS seasonable subject furnishes an essentially picturesque problem, and, besides, the requirements of such a building have a special interest all their own, seeing that the designer is permitted a freer hand in working out the details of his plan than is usually allowable in planning an ordinary dwelling-house, where more hard and fast conditions are imposed by the necessities of the case. The slope, too, of the site on the river's edge materially improves the chances of success. The conditions which we published for the guidance of competitors were as follows:—A Riverside Bungalow, with a boathouse attached. The site is situated on the northern banks of the stream, where good foundations can be obtained; but, to clear the rise of high tides, the stone or brick walling of the basement must be carried up 5ft. above the ground level, which has a fall of two in ten towards the river, and the 5ft. must be taken in the centre of the building, so that on the water side the elevation will be more, and on the land side less. The boathouse or shelter will run out towards the river, and a billiard-room is to be contrived over it. The accommodation of the bungalow to comprise a living-room hall, about 25ft. by 20ft.; a small ladies' drawing-room, about 14ft. by 14ft.; a writing-room or breakfast-room of similar dimensions; kitchen and offices; and seven bedrooms, four of which may be on an upper floor. Style suited for timber and plaster. Roofs covered with tiles or shingles. A feature to be made of a verandah and the stairway leading to the building. Scale, 8ft. to the inch for elevations and section. The plans may be drawn to a scale of 16ft. to the inch if desired. The drawings must adequately illustrate the design, and a perspective sketch to be included.

We felt no difficulty in awarding the first place to "Sphinx," and "The Dodo" comes in a good second, while "Nyoola" ranks third. We illustrate the two first designs among our plates herewith. "Sphinx" concentrates his arrangements better than "The Dodo," and does not waste space over corridors and passages. The entrance, with its lobby, is shut off from the hall living-room, and the kitchen hard by, is fairly well placed for convenient service. The doorways to the billiard-room, drawing-room, and writing-room rather interfere with the comfortable character of the living-room hall. It is not clear where the flue from the hall fireplace is intended to go. The boat-house is effectively handled, and the drawings are well done, without over-elaboration. The homely character both of the external treatment, as well as of the plan, combine to make this Bungalow a success, though we do not say it is by any means above criticism. The general effect speaks for itself, and possibly it may with justice be remarked that the building looks too much like the clubhouse of some well-to-do boating club, as seen from the river. "The Dodo's" design assumes more the home-like character outside, and within there are several advantages contrived with no little ingenuity, though economy of passageways and gallery space has been somewhat overlooked. Both bungalows would work out well in execution, and reflect credit on their authors. "Nyoola" carries out two tower-like bays at the angles of the entrance front to his house, which have rather an ungainly effect externally, and inside scarcely add to the convenience of the building. Had a balcony been introduced on the river front at the level of the gallery over the hall, some excuse would have been in evidence for the return of the aforesaid gallery, which, as it stands at present, is perfectly meaningless. It is to be feared that the kitchen located in the basement level with the boat-house would be somewhat damp, and in the spring tide season would stand the risk of being flooded. The loggia colonnade in the hall shown by the section does not appear on the plan, the area of which such a contrivance would seriously encroach upon. "Heather" comes next, giving several points of no little convenience. His breakfast-room has a very uncomfortable fireplace, immediately in the draught between two doorways. The arrangement of this room near the vestibule has the merit of giving a room for callers to be shown into without necessarily going into the main living-room or hall. The w.c. close to the main entrance is bad, and, moreover, there would hardly be head room in the closet under the staircase placed as this one is. The gallery over the hall fireplace ingle is too directly connected with the servants' staircase landing to be convenient, or to insure a sufficient protection against eavesdropping. It hardly seems necessary to have a back staircase in such a small house as this bungalow, curtailing the larder and taking up room above stairs where every square inch is valuable. The bedrooms on the other side of the bungalow are far better placed than in some of the other designs, as in "The Dodo's" plan, where they are much too near the kitchen to be free from its smells. Externally, the elevation is fairly good, but the perspective is inky and poorly executed. "Xedra" has a good hall living-room in his bungalow, with an open-timbered roof and high dado panelling. Outside the house looks thin, and is devoid of a sufficiently hospitable appearance. The plan looks more convenient that it really would prove to be, because of the dark lobbies and passages, which go far to spoil the arrangements. "Dodo" (Kettering) has overdone his timberwork, in which respect some excuse may perhaps be found for a Northamptonshire man. The hall living-room quite isolates the drawing-room and morning-room from the main vestibule. A little more thought on the treatment of the entrance-hall would have materially improved the convenience of this bungalow. Outside towards the river the result is tame and characterless. "Canary" is regardless of economy, and he draws in a very sketchy and ineffective way. His plan is crude and comfortless. "Full Back" is troublesome, for ever changing his motto, calling himself "Nemo" this time. If he only would display as much care and energy in improving his work as he does in devising fresh mottoes, the consequence would be of more material value to himself and pleasure to us. To remark in detail on his plan would take more room than we have space for. One or two points must suffice. He brings forward his staircase right in front of the main entrance door, and the dining-hall door immediately in a line with it. Thus, every time anyone goes in or out they would have to pass round the staircase or be tripped up. Upstairs a needlessly vast landing wastes more than one-fifth of the entire area. As to the external design, we can only say that it is exceedingly indifferent. "Pallene" is too ambitious, and needs study. Incongruity marks the plan, and lack of proportion his elevations. If he only learns one lesson by this adverse criticism of so poor an attempt at design, his efforts will not have been wasted. That lesson is not to plan pitch-dark passages again. "Minstrel" is quite reckless in the waste of room in corridors, extending his bungalow, regardless of outlay, to an almost limitless extent. His idea for the privacy of w.c. accommodation is an entirely wanting quantity, as the most public points possible are chosen on both floors for these conveniences. "Norvic" sends a quiet solid-looking house, very unlike a bungalow; but in execution, with care in detailing the building, would work out very well. It is not, however, correctly speaking, a bungalow, and the most is not made of the riverview. The drawings, too, are excessively poor. "Bona-fide" sends a sort of suburban tea-garden pavilion, with a belvedere tower as ungainly as it can well be. The building covers a very large area, and has little to recommend it, chiefly because its author has exercised so little thought as to expense, and paid so little respect to the demands insisted on by good taste. "R." in a circle is trivial, with a sort of Moorish minaret over the living-hall, which is treated on plan incorrectly as merely a big dining-room.

AUSTRALASIAN TIMBERS.

IN an article on the timber trade of 1893-94, the "Year-Book of Australia" remarks that the commercial value of Australasian timbers has become recognised only within the last few years. Some of the Tasmanian woods, from the thinness with which they can be cut and the exquisite beauty of their grain, are admirably adapted for veneers. Suites of bedroom and other furniture have been made from Australian timbers at various times in London, where a regular demand would have sprung up had the requisite means of an export trade existed in Australia. As it was, British manufacturers remained unenlightened respecting the probable extent of the supply, and the prices required for large shipments. Consequently, the only colonial timber for which a demand had become created, outside Australasia, was the jarrah of Western Australia, which has always, despite its great weight, been more or less in demand for railway sleepers and piles for bridge and harbour works. There also existed a widely-spread impression that there were only a few kinds of Australasian timbers adapted for industrial purposes, and that of these the supply was limited. On the contrary, the timber forests of Australasia cover many thousand square miles of country, and the importance of systematic forest conservation has become recognised by the various colonial Governments, which have established forestry departments, and also taken steps to prevent the further indiscriminate destruction of growing timber.

Many of the useful timbers of Australasia are species of the Eucalyptus tribe, which seems to thrive in every part of Australasia, imparting to the country a somewhat monotonous aspect. In New South Wales the hardwoods are the most plentiful. Several of these are remarkable for the great size of the beams which may be obtained from them, also for the extreme toughness and durability of the wood, especially the grey ironbark, which has a breaking resistance equal to 17,900lb. per square inch as compared with a mean of 11,800lb. for English oak, and 15,500lb. for teak. All the varieties of ironbark are tougher than English oak. Among the softwoods the red cedar occupies a leading place. It is a beautiful wood, the trees often being of considerable size, as much as 2,500c.ft. of timber being obtained from a single tree. Among other woods are the white maple, rose wood, tulip wood, yellow wood, white beech, myall, marble wood, and mock orange, a few only of the many timbers useful for industrial purposes of every kind. The Moreton Bay white pine grows plentifully in the northern portion of New South Wales and many parts of Queensland. It is said to be admirably adapted for building purposes. There are other varieties of pine, the red pine, which is beautifully marked in the grain, taking a fine polish. Colonial deal is largely employed for house-building purposes. The Queensland timbers are much of the same class as those of New South Wales. Among them are the cypress pine, much used for cabinet work; the she pine, largely employed in joinery; the silky oak from which considerable quantities of staves for casks are made; and the beech, which, being unaffected by climatic conditions, is a favourite material for flooring verandahs, decks of vessels, &c. The wealth of marketable timber in the New South Wales forests, after being neglected for many years, is beginning to be utilised. The Federal Timber Company, formed some few years since for the purpose of expanding the New South Wales timber trade, has undertaken the important work of developing the export trade by placing the more suitable timbers of the colony prominently on the British, European, and American markets. The company has large saw-mills on the Manning River, where operations are conducted on an extensive scale, a tramway, four miles in length, having been constructed for tapping one of the most heavily timbered districts in the colony, and which otherwise would have been unapproachable. The tramway enables logs of immense size to be conveyed to the mills. The Sydney establishment is at Rozelle Bay, Darling Harbour, where the machinery sheds, receiving and shipping yards, wharf accommodation, deep water frontage, &c., are on an extensive scale. The Company's manager, Mr. W. Langley, has been identified with the timber trade for many years, and the success of the undertaking has been largely due to his assiduity and enterprise; also to the able assistance afforded by Mr. J. McSweeney, managing director. The Victorian timbers are much of the same kind as those of New South Wales, the most useful being the red and blue gums. In some places the peppermint or mountain ash attains an enormous height, trees fully 420ft. high having been frequently measured. In South Australia, as in the other colonies, the Eucalyptus tribe is most numerous, but the other kinds of wood found in Victoria and New South Wales are plentiful. The forest resources of Western Australia are enormous, the area occupied by the white gum alone being estimated at about 10,000 square miles. Sandal-wood is abundant, but the principal timber is the jarrah, the forest of which cover an estimated surface of 14,000 square miles. This timber, when properly selected and seasoned, has stood the severest tests, and no limit has yet been discovered to its durability. It is capable of being split into great lengths, and treenails are made with it. Karri is another timber of the same kind as the jarrah, both woods being assigned twelve years by the English Lloyds for use in shipbuilding. The Tasmanian timbers are much the same as those of Victoria, the blue gum being the principal. Among the timbers of New Zealand the kauri occupies the leading place. The kauri is a wood of great durability, well suited for constructive works, house-building, and special purposes. It forms the principal item of timber export from New Zealand, although there are numerous other useful timbers.

In the Australasian timber export trade, New Zealand may be said to have led the way, the first shipments of New Zealand woods being made during the "sixties." In 1870 the value of the timber exported was about £10,000. The progress of the trade since that date is shown below:

NEW ZEALAND TIMBER EXPORTS, 1871—1893.

	Quantity.	Value.
1871	3,214,742ft.	£14,200
1875	5,225,627 ,,	26,914
1881	13,180,280 ,,	65,119
1888	43,474,434 ,,	177,877
1889	42,568,600 ,,	176,608
1890	42,098,863 ,,	181,689
1891	42,824,365 ,,	182,431
1892	22,860,551 ,,	87,581
1893	26,718,046 ,,	101 082

The New Zealand trade is largely in the hands of the Kauri Timber Company, Limited, the Australian head office of which is in Melbourne. It has also an extensive establishment in Sydney, the mills at Blackwattle Bay occupying several acres and having 500ft. of water frontage, with accommodation for three ships unloading at the same time. The kauri is the timber principally in demand, and of this large shipments are received direct from New Zealand, where the company hold several hundred thousand acres of valuable forest land, the trees including the majestic kauri, towering to a height of about 160ft.; the handsome cedar (Pahautea and Kawaka), much used for railway sleepers; the Totara, a most valuable timber; the Rimu, highly prized for cabinet-making: the Pohutu Kawa, unsurpassed for shipbuilding purposes; and other most useful timbers indigenous to New Zealand. The company has about twenty-five saw-mills in various parts of New Zealand, and possesses a stock of 50,000,000ft. of kauri always on hand, the timber—being durable, free from knots, and capable of taking a high polish—being much in demand in place of Baltic pine for floorings, linings, &c., the quantity imported during 1893 into New South Wales alone being 15,000,000ft., of which the company supplied 12,000,000ft.

The Sydney Kauri Pine Agency Company, Limited, recently established in Sydney, has made considerable progress under the management of Mr. J. G. Smith (formerly of the Kauri Timber Company, Limited), in further developing the Australasian timber trade, its operations being principally in kauri timber, of which the company has large and regular consignments direct from the saw-mills in New Zealand. The company partakes much of a co-operative character, the shareholders being mostly the owners of saw-mills in New Zealand, possessing also extensive tracts of forest land, rich in valuable timbers such as kauri, black bird, manuka, cedar, rimu, kowhai, pohutu kawa, &c. The company was formed with a view to enabling producers and consumers to be brought into direct communication with each other, thereby enabling more advantageous business arrangements to be effected. For several years past the exports of timber, principally jarrah from Western Australia, have been comparatively large, amounting in value to nearly £90,000 in 1891. In 1892 the value fell to £78,419, a result of increased demand for railway and other purposes within the colony. The steadily increasing demand in Europe and elsewhere for timbers suitable for railway sleepers and street-paving purposes has naturally had the effect of directing attention to the hardwoods of which Australia possesses such a varied abundance. One result of this was that shipments of hardwood were successfully made from Tasmania, and were followed in due course by others from Victoria, South Australia, New South Wales, and Queensland. The trade thus opened up is capable of indefinite expansion, affording employment to considerable numbers of men. It has been pointed out that timber to the value of £20,000,000 is imported annually into the United Kingdom, and there is no reason why Australia should not enjoy a large share of the business. In New South Wales, as in the other colonies, the initiation of the export timber trade is largely due to private enterprise; Messrs. Scott, Sibbald, and Co., of Sydney, having made several shipments of ironbark, tallow wood, black butt, red mahogany, cedar, rose wood, red bean, beach, and other timbers, to London. They have also sold two lots of tallow wood for export to London, to be used in the construction of railway rolling stock. In addition, the firm has made arrangements for the introduction of Australian timbers into Cape Colony and Natal, to which shipments have recently been made of hardwood railway sleepers. One of the members of the firm, Mr. Gavin Scott, has made an extended visit to the United Kingdom, France, Belgium, and Germany, with a view to ascertaining the full adaptability of Australian woods for wood-blocking, railway rolling stock, parquet flooring, and other purposes in those countries. He has interviewed the managers of the chief railway companies and corporations, and as the result of his inquiries he thinks that there is a good prospect for the Australian timber trade. He has secured several orders for supplies of timber.

The importation of timber into the different colonies is larger than generally supposed, but a considerable portion of the trade is of an inter-colonial character. Subjoined are the latest returns—

AUSTRALIAN TIMBER IMPORTS, 1893.

New South Wales	£13.302
Queensland	6,698
South Australia	165,840
Tasmania	1,927
Total	£187,767

The Queensland timber imports were principally from New South Wales, the United Kingdom, and the United States, the oversea shipments consisting largely of shingles and staves for casks. The Tasmanian imports are principally from Victoria and New South Wales. The Western Australian figures are not available.

AUSTRALIAN TIMBER EXPORTS, 1893

New South Wales	£55,541
Queensland	5,187
South Australia	48,249
Tasmania	18,090
Total	£127,067

Of the New South Wales exports, £25,664 went to Victoria, and £821 to the United Kingdom. The Queensland shipments to the United Kingdom represented £901. The Tasmanian exports were principally to South Australia, Victoria, New South Wales, and New Zealand, from which considerable quantities were re-exported to other countries.

In New South Wales considerable attention has been given to the subject of timber export. Not only has Sir Saul Samuel, the Colonial Agent-General, forwarded to the various London municipal bodies circulars pointing out the advantages of New South Wales hard woods for street-paving purposes; but the New South Government has granted a site on the shores of Sydney Harbour on which to erect works for seasoning timber for the European markets. A large wharf is also being constructed for timber-shipping purposes. Colonial timbers are also becoming more largely used in connection with public works in the colony, the New South Wales Government having accepted tenders from the Federal Timber Company and the Kauri Timber Company for large supplies of Australasian timbers, in addition to the customary importations from Canada and America.

A PROMISING INDUSTRY.

MOST of our readers know the firm of Messrs. W. and R. Leggott, of Bradford, and High Holborn, London, manufacturers of fan-light, skylight, and roof-light openers, mortise locks, door furniture, fire-brasses, brass handrails and fittings generally used in the building trades. Architects, especially, have long been aware that everything is made and fitted on the premises, starting from the raw material to the finished article. The firm has earned a well-deserved world-wide reputation for goods. All the details are watched by practical men. In the foundry, the machinery rooms, fitting-shops, the polishing-rooms, the lacquering and japanning-rooms, the annealing room, and the warehouse, honest work and skilled intelligence control everything. The men employed in the factory have nearly all been brought up and trained from boys in the works. At four o'clock every afternoon the men are all supplied with tea at the firm's expense. The shops are well lighted and ventilated, and the comfort of the workers is studied throughout. For the past ten years the business has been steadily increasing, the receipts to June having been much larger than any previous year since the business was first established. Messrs. Leggott have just turned their business into a limited company, but, as in the majority of cases where the business is a really good thing, it is not offered to the general public; all the shares are in the hands of the proprietors, employés, and friends. The share capital is £30,000, in £5 shares. The business is still capable of further development, as ample room is at the disposal of the firm to cope with the increase of business that is sure to result.

OBITUARY.

THE death is announced, at the age of 77 years, of Mr. JAMES RENWICK, one of the leading architects of New York. Born in that city in 1818, James Renwick graduated from Columbia College (in which his father was a professor) at the age of 17, and became a student of engineering and architecture. A year later, while engaged in field work on the Croton Aqueduct, Renwick won in competition and carried out a commission for a Gothic church at the corner of Broadway and South-street, New York. After an interval, during which Renwick superintended the construction of the distributing reservoir on Fifth-avenue, he entered the competition for the Roman Catholic cathedral on Fifth-avenue, and won this also with a design which is still regarded as an honour to American architecture. These great works brought him many commissions. In New York alone he built the Stock Exchange, Booth's Theatre, and the Young Men's Christian Association building, the Foundling Hospital, and the Ward's Island Lunatic Asylum, besides St. Bartholomew's Church and the Church of the Covenant, and a multitude of smaller buildings, and he was also much employed in other parts of the country. When his business became too large for him to manage by himself, he took a partner, Mr. Sands, who died a few years later, and the late Colonel Auchmuty was for a time a member of the firm, under the style of Renwick, Auchmuty, and Sands. For the past ten years the business has been carried on by the firm of Renwick, Aspinwall, and Renwick.

THE LONDON BUILDING TRADES.*

THE appendix to this work relating to population classified by trades has just been reissued by the publishers as a separate volume, forming the fifth of the series. It is edited by Mr. Charles Booth, who has made a very complete use of the occupation returns of the Census for London of 1891. In an introductory chapter Mr. Booth shows that in the Metropolis in April, four years ago, there were 630,570 occupied tenements of less than five rooms, of whom the largest proportion, just over 60,000, were single rooms let to a single person, another 55,766 being two-roomed tenements in one occupation. The only occupancy at all approaching these in numbers are those where two persons occupy a couple of rooms, which number a little over 46,000. There were at that date in London nearly a million families, averaging in size 4·33 persons, and of these 80·1 per cent. are without servants, and of the remaining fifth 11·3 per cent. keep one or more servants, the remaining 8·6 per cent. being servants and inmates of institutions. Another mode of classification shows that 30·7 per cent. live in poverty, about 8·4 of these being regarded as very poor, and the remainder were divided into 51·5 per cent., comprising the comfortable working class and servants, 12 per cent. lower grade, and 5·8 per cent. middle and upper classes. Although differing among themselves, there is a startling similarity in the percentages between the crowded and not crowded classes and those divided into "in poverty" and "in comfort." In completing the social classification of London, Mr. Booth has not only been assisted by the Registrar-General, but has come into direct communication with the sub-registrar and enumerators, while in dealing with the trades, he has approached many employers, trades-union officials, and individual workmen, so as to gain a fair description of the working of each trade and the wages earned.

The volume before us is divided into three sections: Part I., by Mr. Ernest Aves, deals with "The Building Trades"; Part II., for which Messsrs. G. E. Arkell, G. H. Duckworth, and Esmé Howard are jointly responsible, treats upon "The Wood Workers"; and Part III. relates to "Metal Workers," and for this Mr. Jesse Argyle is responsible, a supplementary chapter on "Workers in Metals other than Iron and Steel" being added by Mr. G. H. Duckworth. The trades and occupations of London are grouped in the census into eighty-nine sections, of which the first nine comprise the building trades, leading off with architects (and engineers), and followed by builders (a very ambiguous title in returns), masons, bricklayers, carpenters, plasterers, painters, plumbers, and gas-fitters. The wood-workers constitute the next four sections—viz., cabinetmakers, carriage builders, coopers, and shipwrights, and the metal-workers a third group of four sections. Of the 91,162 heads of families in the Building Trades group, 3,680 described themselves as architects or engineers, 6,871 as "builders"—an elastic term ranging from master contractors to handy men and labourers, 4,750 as masons, 14,330 as bricklayers, no fewer than 24,805 as carpenters and joiners—the most numerous class, 5,111 as plasterers and paper-hangers, 22,982 as painters and glaziers—another numerous class, 5,141 as plumbers, and only 3,492 as locksmiths and gasfitters. Of the entire number 39·2 per cent. belonged to the crowded class, 31·8 per cent. to the central, and the remainder to the upper class. Figures in tabular statistics are not, however, absolutely reliable. On Mr. Booth's system of classification, for example, the architects would be all grouped near the top of the last class, whereas, from the professional standpoint, the ranks of this section are notoriously "overcrowded." A curious fact is brought out by the returns, that whereas there was from 1861 to 1881 a continuous growth in the Building Trades group—from 87,300 in 1861 to 108,500 in 1871, and 133,500 in 1881—the last Census reveals a sudden drop to 129,500, doubtless due to the fact that as regards building the Metropolis has outgrown the limits recognised by the Registrar-General. The trades have continually moved outwards, and this centrifugal action has now carried many of those engaged in it beyond the Census boundaries. An obvious difficulty in the tabulations is that all branches of the building trades are closely interconnected, and many carpenters, bricklayers, and painters are working under masters in other trades. Excluding architects from the returns, the proportion of employés to employers is, on the whole, one in thirteen. Mr. Aves remarks that the building trades of London supply the most conspicuous example of a great industry carried on in almost complete dependence on a local demand. The fixity of the article produced was one of the essential and peculiar features of the trade; but if incapable of extension by export, it is also free in a hardly less remarkable way from the competition of outside products. Joinery may have been made in a country town or in Norway, stone may be fashioned in the quarries, and granite and marble quarried and polished in Scotland or Italy. But these were exceptions, and even a largely increased use of iron girders and columns would trench comparatively little on the labour expended on the spot. It follows that in London there is always so much work to be done that the building trades must form its most important industrial group. In exchange for the work done away from London in the preparation of materials, the professional skill of the Metropolis is largely appealed to from outside. The London architect or master builder may design, advise, and specify or contract for work that is to be executed in the provinces or in other countries, and from London firms clerks and foremen were sent to all parts of the world. This exchange of services involves in every case some loss to the unskilled and low-priced English workman, and the trained artisans above them reap the advantage. In few instances is the complexity of modern industrial relations more completely illustrated than in the operation of the building trades. The great and rapidly-increasing variety of specialities in the trades—many of them based on patent rights—tends to complicate every transaction, and to cause the original contract between client and builder to cover an increasing number of subsidiary bargains. In London the great concentration of demand differentiates many branches of trade into well-organised departments, in which workers either possess highly specialised skill, or do work with the least possible exercise of personal skill or individuality. In the village and the small provincial town every builder's operative tends to be an all-round man; but, while general knowledge is often great, first-class workmen are rarely found. It is just the reverse in London, which is unrivalled as a finishing school, but a bad training ground. Specialisation of skill is characteristic of London, and a large number of persons, moreover, are entirely employed on processes and products that exist under conditions of monopoly or quasi-monopoly.

Taking the sections in order, a feature of that devoted to architects is the relatively large proportion to the entire population who are over 65. The number in the profession reaches its maximum at 25 to 35 years of age. Passing to the next group, the builders, Mr. Aves points out that the popular association of the speculative builder with the jerry-builder is often misleading; many of the best and most fashionable parts of London have been opened out by the speculative builder. Uniformity of style and a resulting architectural dulness is the charge to be laid to his door, rather than inferior workmanship or the use of bad materials; but it must be admitted that the worst work of all is done by members of this very mixed class, and it probably sinks to its lowest level in many outlying cottage estates. Still, those who do the worst work are simply men of straw, the puppets of the capitalist, who may be the ground landlord, the building company, or the money-lending solicitor. The important part played by subordinates in the building trades, though inevitable, has its bad side: it secures more efficient control, but master and man remain personally unknown to each other. The shifting character of the employer and the payment by the hour tend to accentuate this state of things. The ranks of clerks of works are recruited from many sources,—draughtsmen in architects' or builders' offices, young architects, carpenters and joiners, and operative masons, and bricklayers. The salary paid ranges from £3 up to £10 per week for very exceptional men. The responsibilities are great, and the temptation to swerve is greatest when the need for vigilance is greatest. The general foreman takes the place of the employer in finding, employing, and keeping the right men in the setting-out, and in the apportionment of the labour to the work. The great majority of builders' foremen have been trained in the country as carpenters and joiners. The popular idea of the builders' labourer, as that of the man who serves the bricklayer, is yearly becoming less and less adequate, as the extended use of machinery and of iron and steel is displacing mere labourers. Most classes of labourers now specialise, because of some particular preference or aptitude; but the specialisation, as far as it exists, is purely voluntary so far as trade-union regulations are concerned. Men often follow up some particular branch; but if work fails in that they can, and will, at once try for work in some other branch. Differentiation of the labourers' and the artisans' work is, however, sharply defined, and rigid rules in several trades emphasise this. Passing over the masons' and slaters' sections, Mr. Aves points out that the bricklayer is the recognised "stock hand" of the builder. His sphere of work is wider than any other section of the group, and to him the most miscellaneous work is given. Indeed, his position is now numerically, and, with regard to the offices performed, next to that of the carpenter, the most important in the building trade. In the next section, that of the carpenters and joiners, there is a rather larger proportion of boys than in the other building sections. On the whole, the members rise steadily to 30 or 35 years of age, indicating the establishment in London of men trained in the provinces. After 50 years of age the members fall off rapidly. Many men trained as carpenters becoming caretakers, handy-men, or jobbing builders as they grow old. This class is the best conditioned in the whole group, and are often called "the top hats of the building trade." They form the élite of the trade from the character of the work, from the fact that most of it is done under cover, and from the forethought necessary in acquiring the valuable tools. While, as a rule, men either work on the job or in the shop, there is a considerable amount of interchange; but it is rare to find a first rate joiner excels as a fixer or *vice versâ*. The tendency, therefore, is for the man to specialise, and to work habitually either in the shop or out of it. On the whole, employment is more continuous in the shops, and it is to them that the best men tend.

We cannot afford space at present to give further details from Mr. Booth's valuable compilation, which is, so far as we have tested, accurate in its general statements, and brimful of information of interest and value to the trades, and capable, as will be seen from the points we have summarised, of affording reliable information to the general reader. A commendable feature of the work is the copious and well-arranged classified index at the end of the volume.

---

* Life and Labours of the People in London. Vol. V. London: Macmillan and Co.

Sir W. H. Flower, in writing to the daily Press, makes the timely suggestion that to the statue of Erasmus Darwin in the Natural History Museum, and Brock's statue of Sir Richard Owen in the present Academy exhibition, and soon to be placed in the same hall, a third statue should be added, that of Huxley, completing the trio of the great naturalists of the century.

A picture by Constable, "The Mill at Stratford, on the Stour," included in the collection of the late Mr. C. F. Huth, which was sold by Messrs Christie, Manson, and Woods on Saturday, Monday, and Tuesday, realised the high price of 8,500 guineas. The picture is 50in. by 72in., and was shown at the Academy of 1820. The water-colour drawings and pictures in this collection brought in a total of £27,547, and the miniatures another £2,806.

The first section of the Duke of Clarence Memorial Church at East Llandudno was opened on Sunday. The portion completed is the nave, and on its cost a debt of £2,000 is outstanding. A lady in the county has offered to erect the chancel, at a cost of from £1,600 to £1,800, providing three other ladies will join her in the completion of the church by adding the two other aisles and the tower. Should anyone prefer to give the chancel, the lady in question will build an aisle or the tower. This offer is to remain open a year. The church is being built from designs by Mr. J. Oldrid Scott, F.S.A., and is in the style of the middle of the 13th century. The walls are of local limestone, with dressings of Bromesgrove stone, and for the interior local limestone and Bath ashlar are used, the columns being of Frosterley marble. The completed portion seats 450 persons, but eventually 950 sittings will be provided.

Engineering Notes.

EDINBURGH AND CORSTORPHINE DOUBLING.—The inspector for the Board of Trade, Major Marindin, has just completed a minute inspection of the double relief lines which have been constructed by the North British Railway Company between the Waverley Station at Edinburgh and Corstorphine. Associated with the construction of this doubling of the old lines were the duplicating of the Mound and Haymarket tunnels, an entire rearrangement of the signals to the west of the Waverley Station at Corstorphine and other parts of the line, the widening of several bridges carrying the railway over the Water of Leith and public and private roads, and the extension of the bridge which carries the Caledonian Granton Railway over the North British lines. Accompanying the Board of Trade inspector in this examination were Mr. David Deuchars, superintendent, and Mr. Bell, assistant engineer of the North British Railway. The two new lines which have been made diverge from the main line at Corstorphine, and are carried into the Waverley Station. They will be also continued to Abbeyhill at as early a period as possible, and for this purpose important works are in progress on the east side of the Waverley Station. The Corstorphine Station was reconstructed in connection with the opening of the Forth Bridge, and needed no further alterations. From Corstorphine to Haymarket the new lines are laid on the north side of the railway, and the bridges enlarged towards that side are those over the Water of Leith, over a farm road at Saughton Hall, over the public road from Gorgie to Corstorphine, over a farm road at Damhead, and over a new road at Roseburn. This bridge is of steel girders, resting on brick abutments. The sides of it facing the roadway are lined with white enamelled brick, and Hayward's patent roof lights have been introduced. The Water of Leith Bridge now consists of a span of 50ft., with two side spans of 15ft. each, constructed entirely of masonry, with brick and cement arches. The Caledonian overhead bridge is of steel girders, and is now in two spans instead of one as formerly. New engine sheds have been erected at Murrayfield capable of "stabling" forty-eight engines, and on the north side is a range of workshops. The Haymarket Station has been entirely renewed and enlarged. Nothing, indeed, remains of the previous structure but the old booking-hall, which was part of the original terminus of the Edinburgh and Glasgow line. The new station consists of an island platform and two side platforms, over 600ft. in length, and on the north-west side a small dock. On the island platform, which is 25ft. in width, are blocks of waiting-rooms; and waiting and other rooms have been formed on the south platform. The new Haymarket tunnel, constructed on the south side of the old tunnel, from which it is separated by a block of 25ft., was at the same time inspected and passed by the Board of Trade inspector. It is 1,000 yards in length, 27ft. in width, and 18ft. 6in. in height from the rail level to the top of the arch. It is constructed of six concentric rings of brick grouted with cement, and at points where it passes under buildings it is of the thickness of eight rings. The tunnel is ventilated by two large open shafts at Torphichen-street and St. Cuthbert's-lane. Over the widened railway in the West Princes-street Gardens three new foot-bridges have been thrown. Two of these are of 96ft. span, and the other of 104ft. span. Two are 6ft. in width, and one, the westmost, is 10ft. New single-line tunnels have been pierced on each side of the old Mound tunnel. These are 120 yards in length, and 18ft. 6in. in diameter. They constitute a complete iron tube, the face of which, with its boltings and flanges, is incased in concrete. Many difficulties were connected with the construction of the northmost tunnel, through a mound of made-up earth, and underneath a heavy building like the Scottish National Gallery. The west end of the tunnel has been treated in ashlar work, and with its simple Classical architectural lines appears to form, from the garden, a base for the National Gallery. The new lines, tunnels, &c., will be brought into use in the course of this month. The contractors for the Haymarket tunnel were G. Lawson and Son; for the widening of the lines and engine sheds, James Young and Son, Edinburgh; and for the Haymarket Station, G. and R. Cousins, Alloa. The whole of the works were carried out from designs by the company's chief engineer, Mr. Carswell, under the supervision of the assistant engineer, Mr. James Bell.

LOSTWITHIEL.—The opening of the new viaduct at Milltown and the double line from that place to Lostwithiel took place last week. Two years ago the double line from Lostwithiel to Bodmin-road was opened. Not long afterwards, another section was opened, that from Bodmin-road to Liskeard, and later on the railway company opened a double line between St. Austell and Par. The only thing then required to have an uninterrupted double line from St. Austell to Liskeard, a distance of 20 miles, were two sets of rails from Lostwithiel to Par. That, however, could not be until Brunel's old wooden viaduct at Milltown, about a mile west of Lostwithiel, had been replaced by a stone structure. The excavations for this viaduct were commenced in October, 1893; and the double railway from Par to Milltown was opened on the 19th December last. The new viaduct, which completes the widening, has been built by Messrs. Relf and Son, of Plymouth, Mr. W. H. Blackall, of Liskeard, being the engineer. Mr. G. Westlake superintended the work, whilst Mr. C. H. Pickford watched the work on behalf of the railway company. The viaduct is 434ft. long, 26ft. 6in. wide, and is 70ft. high. It has five piers of granite, with two abutments, and there are six arches of label brick. The spandrels, string-course, and coping, are of granite, whilst the parapet walls are of brick.

Building Intelligence.

BEBINGTON, CHESHIRE.—The new Wesleyan school-chapel at Bebington was opened on Thursday last. The work has been carried out by Messrs. W. H. Bleakly and Co., of Birkenhead, from plans prepared by Mr. T. Taliesin Rees, A.R.I.B.A., also of Birkenhead. The contract was £930, furniture and fittings £100. The building is faced with red pressed bricks, relieved with white Storeton stone dressings; woodwork pitch-pine. The windows are filled with cathedral lead lights. The design is Late Gothic. The accommodation includes school-chapel for 300 persons, two vestries, kitchen, w.c., lavatory, heating-chamber, &c. The above is the first portion of a large scheme, the plans of which have been prepared by Mr. Rees, and includes a large chapel, vestries, &c., to cost about £3,000.

DALRY, N.B.—The new baths erected at Dalry by the corporation of the city of Edinburgh will be opened in the course of a week or two. The building is constructed of bricks, with a stone front to Caledonian-crescent. The entrance-hall is laid with tiles. The swimming-pond is 75ft. by 35ft. The plunge-baths are 40 in number, 28 second and third-class on the gallery upstairs, and 12 first-class in a separate part of the building. There are also spray and needle-baths, and foot-baths, and a laundry. Most of the pipes used are of iron, and the whole of the metal fittings are nickel-plated. The plumbing, sanitary, and gasfitting work has been carried out by Messrs. Wilson, Morrison, and Co., Edinburgh. The estimated cost of the building, exclusive of site and furnishings, is about £9,000.

EMPINGHAM.—On Thursday in last week the parish church at Empingham, near Stamford, Rutland, one of the largest and most important in the diocese of Peterborough, was reopened after much-needed restoration. The work of restoration has been carried out under the superintendence of Mr. J. C. Traylen, of Stamford, the diocesan surveyor, and the contractors were Messrs. Edmund Roberts and Son, of Weedon, Northamptonshire. The cost, about £2,000, has been defrayed almost entirely by Miss Cooper. The church was built in the 12th century, and was partially rebuilt in the 13th and 14th centuries. The south transept, windows, buttresses, and mouldings, as well as a great deal of the painting on the walls, belong to the Early English period. To this Decorated period belong the northern arcade of the nave, the chancel arch, and the south doorway and porch. The present restoration was necessitated by the rotten condition of the roofs throughout. The crushed and insecure state of one of the pillars rendered imperative its renewal on a new foundation. Other pillars and the remainder of the fabric have been made secure. In the windows every scrap of the old glass has been used up, including bits of stained material and coats of arms. The plaster also has not been scraped, but retains its ancient face, with scraps of wall painting thereon. New oak roofs, with thick lead covering, have been put up, the pattern of the old ones having been followed as closely as possible. The floor has been laid with stone instead of with tiles. New wood-block flooring covers the seating area, and for the present the worshippers will be accommodated with 300 chairs, supplied by Mr. W. Royce, of Stamford. Hot-water piping circulates round the nave and chancel, the heating arrangements being carried out by Messrs. J. L. Bacon and Co., of London. The tower and spire have been pointed, the pinnacles have been restored, a lightning conductor has been supplied, and the parapets have been attended to. The chancel has not been touched. Outside, the ground has been lowered round the north side.

RYDE, I.W.—The new pavilion on the pier at Ryde was opened with much ceremony on Thursday in last week. The pavilion occupies a portion of the open space that exists between the promenade pier and the railway pier. It is carried on 39 iron columns, framed together with steel rolled joints and circular tie-rods, each tie being adjusted by means of a right and left-handed screw coupling box, the foundations for these columns being bell-shaped castings sunk below the surface of the ground. The building consists of an octagonal concert hall and annexe. The former is 65ft. in each direction, capable of seating 700 people on the ground floor. In the concert hall, 14ft. above the ground floor, there is a promenade gallery 10ft. wide, carried by ornamental columns. The stage accommodates 25 performers, and has two dressing-rooms. The annexe contains on the ground floor a public refreshment-room, a private refreshment-room, ladies' and gentlemen's retiring rooms, entrance hall, and board-room, and on the first floor a room for the Royal Victoria Yacht Club with a private staircase, a second room with a large balcony over the porch, and a reading-room with a balcony. Round the base of the dome and on a portion of the annexe roof there is a promenade. The interior decorations are carried out in cream and yellow with terracotta canvas panels. Messrs. Grace, of Southampton, were the contractors.

WESTMINSTER.—Further details have been published as to Mr. J. F. Bentley's finally-approved Early Byzantine design for the R.C. Cathedral, from which it appears that, while the interior will be of common yellow brick, to be cased with marble and mosaics, for the exterior red brick, terracotta, and stone will be used. Generally, the external aspect will be one of plainness, depending rather on broadness of treatment and carefully-studied outlines, than on an exuberance of detail; but it is intended to make the entrances a great feature. The one at the western end will be surrounded by a composition measuring nearly 50ft. in height by a width of 30ft., and the great tympanum formed by the inclosing arch is to contain a seated figure of Our Lord flanked by the Blessed Virgin and St. Peter, considerably over life size. Near to this doorway will rise a campanile to an altitude of 300ft., capped with a belfry-story with domical roof. Little will be seen of the roofs, excepting those that cover the apsidal end over the Monks' Choir, and the two easternmost chapels of the Blessed Sacrament and Our Lady. The total sum promised towards the £150,000 required is £75,492, of which £42,870 is virtually in hand.

* * *

Mr. L. A. W. Rind, Deputy Conservator of Forests in the Central Provinces of India, died on Sunday at St. Stephen's-road, W., aged 46 years.

Among the measures which received the Royal Assent on Monday were provisional orders authorising the London United Tramways to construct additional lines at Hammersmith and Acton, another empowering the Corporation of Windsor to undertake the electric lighting of Windsor and Eton, and a third empowering the London School Board to acquire 73 additional sites for educational purposes.

The town council of Rochdale are seeking powers to borrow £40,000 for works of sewerage and sewage disposal. In connection with one section of this undertaking they have appointed Mr. G. F. Deacon, C.E., of Liverpool, to act as engineer in the laying of the main sewer under the canal near Well-i'-th'-Lane, a troublesome operation, for which Mr. Deacon will be paid a special fee of £200, in addition to having the services of a clerk of works at a salary of £4 a week. The corporation will have to pay a penalty of £10 an hour should a leakage occur.

"JOHN MILTON AT THE AGE OF TEN," BY JANSSENS.—R.I.B.A. MEDAL DRAWINGS OF LLANDAFF CATHEDRAL.—NEW WAREHOUSE, BELFAST.—DESIGNS FOR A RIVERSIDE BUNGALOW.

Our Illustrations.

"JOHN MILTON AT THE AGE OF TEN."

This picture, by C. Janssens, is now in the collection of Mr. J. Passmore Edwards. It is one of the few, possibly the only, authentic portrait of the great Puritan poet at that early age. It was formerly in the possession of Mr. Thomas Hollis, from whence it descended to the gentleman on whose account it was sold by Messrs. Christie, Manson, and Woods on May 3, 1884, when Mr. Passmore Edwards purchased it. It was originally bought by Mr. Hollis of the executors of Mr. Charles Stanhope, who bought it of the executors of Milton's widow for twenty guineas. Such was the value in which Mr. Hollis held the painting, that when his lodgings in Covent Garden were on fire he "walked calmly out of the house with this picture by Janssens in his hand," leaving everything else to the flames (Tod's "Life of Milton," edit. 1809, p. 142). The picture was engraved by Cipriani in 1760, and a copy of the plate appears in Hollis's "Memoirs" (1780). It was also engraved by Gardiner, and published by Boydell in 1794.

LLANDAFF CATHEDRAL: ROYAL INSTITUTE OF BRITISH ARCHITECTS SILVER MEDAL OF MERIT PRIZE DRAWINGS.

These excellent drawings, comprising a monograph of this the greatest of the Welsh cathedrals, obtained the first Medal of Merit in the late R.I.B.A. competion for the year's prize. Mr. John H. James has sent us the following account of the building. Llandaff is a place of high antiquity, and, if not the first Christian fane erected in this island, was certainly the seat of the first Christian bishopric, having been founded early in the 5th century. The present structure stands on the site of an earlier and smaller cathedral, which was dedicated to SS. Peter and Paul, and founded by St. Dubritius, the first bishop of the See. The smaller cathedral consisted of a nave with aisles and an apse, and remained standing in 1120, but in a very dilapidated state, owing to the wars of the preceeding century. Bishop Urban, (1108-1136) rebuilt the cathedral, but still of small dimensions. The nave, it has been presumed from ancient drawings, was equal in extent to the present presbytery and one bay of the choir, and the choir with the Lady-chapel, and probably had no aisles, but a lateral tower with a baptistery below it, where the vaulted vestibule to the chapter house now stands. The see was utterly impovished at and soon after the Reformation, and the cathedral gradually got into a state of ruin. The decay went on steadily for centuries, and in 1718 Llandaff was in serious danger of being abolished altogether, a proposition having been entertained of moving the see to Cardiff. In 1752, however, sums were collected sufficient to prevent the whole building from going to ruin and an abominable Italian temple was erected inside the building, shutting off the choir from the nave, at a cost of £7,000 used in the most wretched waste. In 1835-6 the Rev. Henry Douglas, precentor of the cathedral, gave the first impulse to the restoration, which has been carried out by Deans Knight, Conybeare, and Williams. Dean Conybeare's well-known interest in the structure has evinced itself in his effort of restoring the fabric which had long served only as a small parish church, to a portion at least of its primitive magnificence, and rendering it available for study as a good specimen of English Mediæval architecture. And although the cathedral church of Llandaff can assert no comparison either in the exquisite richness of architectural beauty or history with such of its English sisters as Salisbury, Lichfield, and Ely, and even less with those of Canterbury, York, and Norwich, it can certainly claim supremacy both in elegance of detail and magnitude, over all other churches of its kind in Wales, and represents one of the finest and most remarkable results of church restorations in the country.

John H. James.

WAREHOUSE, BELFAST.

This building is now in course of erection for Messrs. R. Watson and Co., of Belfast, Ltd., and is situated on a triangular-shaped piece of ground at the junction of Library and Little Donegall-streets. The building is fireproof throughout, and is faced with local red bricks and terracotta. Mr. William J. Fennell, of Belfast, is the architect for the work, which is being carried out by Mr. James Kidd, builder.

"BUILDING NEWS" DESIGNING CLUB: A RIVERSIDE BUNGALOW.

(See description on p. 42.)

◆

The trustees of the National Gallery have just acquired, by purchase from Messrs. Dowdeswell, New Bond-street, a picture painted in 1808—"Smugglers on the Irish Coast"—by Julius Cæsar Ibbetson.

In the statement of affairs issued by the Official Receiver relative to the estate of Mr. Allen Holmes, of the Railway Saw Works, Turner-street, Ashton-under-Lyne, builder and contractor, the liabilities unsecured amount to £3,047, and the assets to £3,392 7s. 8d., leaving a surplus of £345 3s. 1d. The causes of failure are said to be "paying too large a composition in 1892, bad trade, the long frost last winter, loss of credit, bad health."

The Prince of Wales, who was accompanied by the Princess of Wales and the Princess Victoria, visited the Royal Benevolent College at Epsom on Monday, and laid the foundation-stone of the new Lower School. The buildings, which will cost £13,000, are being built from designs by Sir. A. W. Blomfield and Son, and were illustrated in our issue of the 21st ult. Messrs. Dorey and Co., of Brentford, are the contractors, and the clerk of works is Mr. Harding, of Epsom.

A sub-committee of the Lord Provost's Committee of Edinburgh Town Council had before them on Monday a motion for the extension of the municipal boundaries of the city. After examining a plan prepared by the city road surveyor, showing the proposed extension, it was agreed to recommend general approval of the scheme, and to ask a remit to further consider details and report, with a view to proceeding this year for the necessary Parliamentary authority, should that be resolved upon. The proposed extension of the municipality follows the boundary lines of the new city parish, and also includes the burghs of Leith and Portobello.

A stained-glass window has been placed in the south side of the chancel of St. Michael's Church, Bournemouth, as a memorial of the late Captain G. Maxwell Goad. The subject represented is the finding of the child Jesus in the Temple. The prominent figures in the foreground are Gamaliel and Hillel, and immediately behind Christ is Abbas. In the architectural canopy-work above the subject are angels, holding scrolls, on which appears the quotation from St. John xii. 46, and in the topmost piece of the tracery is the emblem of the Holy Spirit.

Sir George Hayter's historical picture of "The Trial of Queen Caroline" is to pass into the custody of the National Portrait Gallery. The picture is a large one, measuring 13ft. 9in. by 8ft., and was painted for the first Lord Dover. It is an heirloom, and so could not be included in the sale of the Clifden properties. The picture has been for some time on view at Mr. Vokins's gallery in St. James's-street. The heads in the picture are nearly all portraits, and its value is greatly enhanced by the key by which it is accompanied.

COMPETITIONS.

Aston Union, Birmingham, New Cottage Homes.—The guardians for this union recently instituted an open competition for cottage homes. Numerous sets of designs were submitted by architects. Mr. William Martin was appointed assessor, and he selected the designs prepared by Messrs. Franklin Cross and J. R. Nichols, of Union Chambers, Temple-row, Birmingham, and awarded them the first premium of £70. The guardians have since resolved to appoint the first premiated architects to carry out the work. The architects' estimate for the homes was £25,200. The scheme embraces homes for boys and girls, probationary home, school, place of worship, infirmary, workshops, swimming-bath, bakery, stores, superintendent s house, fire-engine station, &c.; these will be erected on a site near to the Gravelly Hill workhouse, but will have no connection with that establishment.

Ipswich New Workhouse.—In this competition the Ipswich board of guardians have received a report from the assessor, Mr. Charles Barry, F.S.A., of Westminster, awarding the first premium of £100 to Mr. Percy D. Adams, of Woburn-square, son of Mr. Webster Adams, of Ipswich, and the second premium of £50 to Messrs. Tree and Price, of London. The limit of outlay was £20,000.

CHIPS.

At Weston-super-Mare, Bishop Auckland, and Brechin ½d. per hour extra has been granted to carpenters and joiners, and a code of rules signed by the employers.

The Bristol Corporation have sold the site of the old gaol for £22,500 to the Great Western Railway Company, who require the property for the extension of their siding accommodation in that city.

On Wednesday week Miss Gretton laid the foundation-stone of a new church at Stretton, near Burton, the entire cost of which, estimated at over £15,000, is to be defrayed by her father. The architects are Messrs. Somers Clark and Micklethwaite, of Westminster, and the builder is Mr. Halliday, of Stamford. The church is to accommodate over 400 worshippers.

Business premises in Fore-street, Devonport, have just been rebuilt. Mr. H. G. Luff is the architect, and Mr. Potter, also of Devonport, is the builder.

The transactions last week at Tokenhouse-yard were very satisfactory, the official returns showing an aggregate of £223,640, which is the highest total reached during the present year.

Foundation-stones of the new chancel and north aisle extension, now being added to the Church of St. Mary Magdalene, Rodborough, near Stroud, were laid on Monday.

The new promenade along the sea front at West Looe was formally inaugurated on Friday. It has been constructed from plans by Mr. Joseph Thomas, C.E., by whom the Hannaford Estate, to which it forms a frontage, is being developed. It is proposed to build about 200 villas in two rows overlooking the sea.

The noble parish church of Ledbury will be reopened by the Bishop of Hereford, after restoration, on Wednesday, July 31.

The Grange-over-Sands Congregational Church, now approaching completion, to the designs and under the superintendence of Mr. E. Howard Dawson, A.R.I.B.A., F.S.I., architect, of Lancaster, is ventilated by means of Shorland's patent exhaust roof-ventilators and specially-designed inlet tubes.

Alderman Arthur Hill has offered to present to the town of Reading the facsimile of the Bayeux tapestry which has recently been exhibited in the Reading Town-hall. The Reading Town Council have accepted Mr. Hill's offer, and the production will be hung in the new Art Gallery and Museum now being built at Reading.

The spire at St. Mary's Church, Devonport, which is in an insecure condition, is about to be restored from plans by Mr. Henry C. Luff, of that town, who has given his services.

The London County Council, on Tuesday, deferred consideration of a report by the Asylums Committee which recommended the expenditure of £9,500 upon alterations and improvements at Claybury Asylum.

The Duchess of Teck visited Bloomsbury on Tuesday for the purpose of opening the new buildings of the London Homœopathic Hospital in Great Ormond-street, which have been erected at a cost of £45,000 (of which £10,000 is still unsubscribed), and provides accommodation for 100 patients. Mr. Alfred Robert Pite is the honorary architect.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING FOR TWENTY-FOUR WORDS, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—R. J. Lavenham.—Associate.—N. G. and Co.—J. W. F.—C. G. (Belfast).—M. F. C. Co.

J. T. (Full up for months to come. Why do not you and the rest of the younger men who send these endless series of poor perspectives of houses and churches turn your endeavours to the preparation of decent sheets of *working drawings*—sections, plans, elevations, and the like? You have no idea how much more likely these are to impress builders and clients with a sense of your ability than mere perspectives. Working drawings—even of the most ordinary buildings—are always welcome.)

Correspondence.

SOWERBY BRIDGE BOARD SCHOOL COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—I note in your last issue the result of competition for new Board School, Sowerby Bridge, Yorks. This competition is notable from the fact that the board offered only 3½ per cent. remuneration for all the usual architect's work, including complete builder's quantities, and there being no clerk of works the architect was expected to take the extra superintendence, and finally the competing architects were expected to take their own measurements of site.

One would have thought that the architects of the district would have shown their contempt for such a glaring attempt at architectural sweating by abstaining from competing; but the sequel has, however, shown such an exalted view of professional prestige, if not morality, to have been fallacious, four firms having responded to the invitation.

I note also in your report, and I have taken the trouble to verify its accuracy, that one of the quartette is an *Associate of the Royal Institute of British Architects* "and another a *Fellow of the Institute of Surveyors.*" I will make no comment upon the action of these gentlemen in competing; but would, however, like to ask for an expression of opinion, if I am correct in my surmise, that both of the institutes named look to their members to uphold the dignity and well-being of their several professions, and if it is the correct thing for members of such institutes to associate with, and lend the countenance of their names in connection with, public competitions for work offered at unrecognised standards of remuneration.—I am, &c., REFORMER.

CHIPS.

A tablet has been erected in Holy Trinity Church, Tunbridge Wells, to the memory of the late Canon Hoare, for many years vicar of the parish.

Sir Frederic Leighton and Mr. Walter Crane have received second-class medals at the International Exhibition at Munich.

On Monday a memorial chapel and vestry were opened at St. Mary's Church, Dover, dedicated to the late Canon Puckle, who died last year after being vicar of the parish for over 50 years.

In the list of receiving orders published in Tuesday's *London Gazette*, the name appears of Henry Vulliamy, of Loftus-road, Shepherd's Bush, W., and Lawrence-lane, Cheapside, E.C., architect.

A Conservative club is about to be built in Fore-street, Devonport, from designs and plans by Mr. H. G. Luff, of that town.

The new bank buildings which Messrs. Wm. Brown and Co. are erecting in Park-row, Leeds, have been intrusted to Messrs. Alfred Waterhouse, R.A., and Son. The ground has now practically been cleared, and the work of building will be proceeded with rapidly.

A feature of the Industrial Exhibition to be held in Berlin is a separate pavilion, covering about 1,200 square yards of ground, to be devoted to modern city improvements. Here will be shown the details of the management of educational, hospital, and benevolent institutions. An exhibit will also be made of sewerage, gas, and water systems, as well as of bridges, markets, and public baths. These will be illustrated by models and drawings, as well as by original objects.

Dr. Whiteside, the Roman Catholic Bishop of Liverpool, laid the foundation-stone on Sunday of schools which are to be erected in connection with St. Charles' Catholic Church, Aigburth-road, Liverpool. The new school premises will accommodate 150 children, the dimensions of the building, which is to comprise schoolroom, classroom, and cloak-room on one floor, being 46ft. by 44ft. Messrs. Sinnott, Sinnott, and Powell are the architects, and the contract is let to Mr. Fogarty, Old Swan, the estimated cost being £980.

At the half-yearly meeting of the London Tramways Company held on Tuesday, it was reported that £50,000 worth of debentures had been issued, the money being required to extend the system of tramways for three-quarters of a mile from the present cable terminus at Telford-avenue, Streatham Hill, to Streatham Common, to build a granary at East Greenwich, and to add to the company's stabling at Camberwell-green.

Mr. Justice Wills on Saturday gave judgment in the action brought by Messrs. Clutton, estate agents and surveyors, of Whitehall, against Messrs. Attenborough, to recover £3,500, the proceeds of a large number of cheques which the defendants had cashed for a man formerly in the employ of the plaintiffs, who misappropriated moneys during eight years. He came to the conclusion that the defendants had received the cheques honestly, and he, therefore, entered judgment in their favour, with costs.

The death is announced, at the age of four-score years, of Mr. John Absolon, the well-known miniaturist and water-colour draughtsman. He was for many years treasurer of the Royal Institute of Water Colour Painters, and to the exhibitions of that body, and of the New Society of Painters in Water Colours, he had contributed during the past 56 years no fewer than 660 works.

The memorial-stones of a Sunday-school for the Primitive Methodists at New Shildon, to cost £1,100, and provide for 350 scholars, were laid on Saturday.

At the last meeting of the Burnley Town Council, the appointment of Mr. George H. Pickles, assistant surveyor, to the position of surveyor, at a salary of £250 per annum, was confirmed. A long discussion took place on the appointment of Mr. Button as consulting engineer to the corporation for a period of two years, at a salary of 100 guineas per annum. An amendment that the appointment of Mr. Button be referred back for consideration, by three committees, was lost, and the recommendation of the committee agreed to. A saving of £350 a year will be effected by the new arrangement.

In consequence of the union of the West and South United Presbyterian congregations in Duns, the church of the former was no longer required by the congregation. It has just been put up to public auction, and knocked down at £170. It cost £2,000 to erect 74 years ago.

Intercommunication.

QUESTIONS.

[11378.]—**Steps in Churches.**—Will some reader interested in ecclesiological matters answer the following query, which can but interest a large number of people, although the point has been more often overlooked than is generally supposed? It is evident, from the lowness of the sills of the east windows of a large number of Mediæval chancels, and also the position of their sedilia, that more than one step at the entrance to the chancel must frequently have been left out, and where they have been erected I fancy these steps are of subsequent date, if not actually modern. At Sompting, in Sussex, and Barfreston, Kent—another very Early church—not to name other examples, there are steps actually down into the choir, and at Sall, in Norfolk, the east window is a specimen of the use of the low-level sill with no steps into the chancel, and I fancy there are none at Blythborough, in East Suffolk. An elevated platform at the west end is a very common feature in our old parish churches, with steps down into the nave. I want to know what was the usual level of the sanctuary as compared with the floor of the nave, generally speaking, in parish churches before the Reformation and also afterwards? Secondly, was the elevated platform at their west ends, as above described, mainly due to the exigences of the churchyard level outside, or was there any other reason? It is not at all an uncommon arrangement to step down into the church, too, out of the S.W. porch, and in such cases the steps are clearly often the original ones, and have not been inserted because of the accumulation which time has raised in the level of the churchyards. Economy of height to avoid expenditure cannot be urged as the reason where outlay of labour and money surely must frequently have been little considered, seeing how rich and elaborate the architecture of our old churches for the most part was. I should be glad of a reply.—LANDED PRROPIETOR.

[11379.]—**Valuations.**—What is a fair charge for making valuations for the purposes of Probate? The valuation in my case was of freehold land and farm buildings in different parts of the country, and amounted to about £40,000.—ARCHITECT.

REPLIES.

[11375.] — **Northamptonshire Churches.** — "Bicyclist" cannot do better than carefully study "Churches of the Nene Valley," by Mr. John Johnson and Mr. A. H. Kersey, which gives sketches and details of the most interesting buildings.—H. L.

[11376.]—**Right of Support.**—If the person making the excavation took all necessary precautions, such as shoring and strutting, he cannot be made liable. It is difficult to decide such a point without seeing the building and knowing the actual facts.—H. L.

[11377.]—**Water Colours.**—For tinting new stonework in elevations, use lignt sepia, raw umber, or very light Payne's grey. Avoid using a tint similar to that used for other materials.—H. L.

The new English church of St. James the Apostle, at Grindelwald, will be opened on St. James's Day, June 25, when the sermon will be preached by the Dean of Norwich. The cost of the church will be about £2,200, and it will seat 300 persons.

With the object of obtaining spring water for brewing purposes, boring operations by means of the diamond drill process have recently been carried out on the premises of the Lion Brewery Company, Pepper-street, Chester, by Messrs. Thom, well engineers, of Patricroft. An abundant supply of good water was found at a depth of 500ft., the whole of the borings—9in. diameter for the first 200ft. and afterwards of 6in. diameter—passing through solid sandstone.

Mr. Laws, the borough engineer of Newcastle-on-Tyne, has issued a report on the proposed sectional scheme of cable trams in that city. They will run out for 12½ miles, and the cost, including engine-houses, engines, track, &c., but exclusive of land, he estimates at £125,000. The widening of Byker Bridge is suggested, and that will cost an additional £5,000. He gives the preference to cables above all other systems.

At Friday's meeting of the Rochdale town council the chairman of the Paving and Sewering Committee reported that the Local Government Board had given sanction to the corporation for the borrowing of £40,000 on condition that extra land could be had at their sewage farm, and that they had permission from the Railway and Canal Companies to make the sewers under the railway and canal. They had obtained the consent of both companies, and had engaged Mr. G. F. Deacon, C.E., of Westminster, to superintend the work required in carrying the Sudden Valley sewer under the Rochdale Canal. Mr. H. G. F. Barham, of Pontypridd, had been engaged to act as resident engineer. The report was adopted.

On Saturday afternoon the foundation-stone of the Victoria Jubilee Technical School at Preston, now in course of erection on a site comprising 5,879 square yards, in Corporation-street, Preston, given by the corporation, was laid by Mr. W. Ascroft, J.P., president of the Harris Institute. The Harris Institute have given grants of £10,000 to the building fund, and £20,000 for the endowment of the schools. Messrs. Cheers, Aspinall, and Smith, of Blackburn, are the joint architects.

Legal.

THE BUILDING LINE.

DISPUTES about building lines are common enough, and there have been numerous cases affecting the matter; yet it is not clear who is to decide what is the line—the architect to the local authority, or the magistrate before whom the case is brought. It is certainly time that this primary point, at all events, was finally settled, and so it may be hoped that the recent case of "Allen v. London County Council" (*Times*, July 2) will be taken to appeal, in order that a clear and conclusive decision upon so important a principle of practice may be obtained. This case arose over some shops which had been built upon land at the corner of Birchington-road, Kilburn, having a frontage of 22ft. in the Kilburn High-road, and of 58ft. to the Birchington-road. The front of the houses and shops in Birchington-road extended 16ft. beyond the building line for that road as determined by the certificate of the superintending architect of the London County Council. The contention of the Council was that his certificate was final and conclusive, and binding on the Court, and upon the summons before him the magistrate had adopted this view, and made an order for the demolition of the houses as far as they were beyond that line. From this ruling the owner now appealed, the point taken, however, being the technical one that the certificate did not sufficiently define the position of the shops affected.

But on the hearing before Justices Wills and Wright, those learned Judges, while following the case of "Barlow v. St. Mary Abbott's, Kensington" (11 App. Ca. 257), did not hesitate to say that this was most unsatisfactory. They pointed out that, although Lord Watson had there held unhesitatingly that the architect was the person to decide the building line, Lord Bramwell with equal emphasis had held that it was for the magistrate; but as Lord Fitzgerald followed Lord Watson, his opinion prevailed, but it still left the weighty judgment of Lord Bramwell the other way. Following these judgments, the Divisional Court now held that the certificate of the architect was binding, and so they confirmed the magistrate's order; but they explained that they did this solely in deference to the opinions of the various Judges, and apparently rather against their own views of the question. The result is that in this case a frontage in the high road of 28ft. is cut down to one of only 12ft., as the houses must be put back 16ft. to meet the building line of the side road. Seeing how much property may be at stake, it seems doubtful whether, apart from the point as to what really is the law, it is fair and just that the decision should lie in the hands of an official of any kind.

Fred. Wetherfield, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

The school board for Harpenden have adopted plans by Mr. Anscombe for new board schools.

The Duke of Devonshire will preside at the banquet of the Sussex Archæological Society, at the Queen's Hotel, Eastbourne, on Thursday week, 25th inst.

At a meeting of Aberdeen Harbour Board, on Tuesday, Mr. William Smith, the harbour engineer, intimated his resignation, and trusted that, in consideration of his services during the past twenty years, an adequate honorarium in lieu of retiring allowance would be granted. Mr. Smith's resignation was accepted, and an honorarium of £1,000 was granted to him on demitting office.

The artists at Newlyn are so well satisfied with Mr. Gregory Jones's frescoes over the chancel arch of the "church of the painters" that he has been commissioned to decorate in a similar manner the whole of the walls. The expense of this will be defrayed by the Rev. R. Peel Yates, the son of the General depicted as presiding in last year's celebrated Academy picture, "Gentlemen, the Queen!"

At the last meeting of the Edinburgh Town Council, Mr. W. N. Colam, M.I.C.E., M.I.M.E., was, in conjunction with Mr. Cooper, the burgh engineer, elected engineer for the construction of 18 miles of cable tramways which are to be laid down at once in the city.

LEGAL INTELLIGENCE.

Powers of Vestries over Sewers.—The Queen v. the Vestry of St. George, Hanover-square.—Mr. Justice Wright and Mr. Justice Kennedy gave judgment on July 4th, in the Court of Appeal, on a rule calling upon the Vestry of St. George, Hanover-square, to show cause why a writ of *mandamus* should not issue directed to them commanding them to comply with an order made by the London County Council, dated December 4, 1894, directing the vestry to construct a sewer therein described, or to execute sufficient works to secure the communication with the main sewers of the Metropolis of the sewer or drain receiving sewage from the premises in the said order mentioned. The question was whether the London County Council has the power of taking the initiative by ordering a vestry to construct specific sewers which the Council in its discretion thinks ought to be constructed.—Mr. Justice Wright, in giving judgment, said,—The question is whether the County Council, as representing the old Metropolitan Board of Works, has the power of compelling the vestry to construct this sewer. By section 135 of the Metropolis Management Act, 1855, the Metropolitan Board of Works was intrusted with the powers over sewers; not an absolute duty, but with powers. The question is whether section 138 authorises the County Council, which now represents the old Metropolitan Board of Works, to make the order in question. Stated shortly, it appears to me that the section does not empower the County Council to take the initiative by ordering specific new works of sewerage. I think if a new sewer is made it must be made in such a way as the County Council approves, but I see nothing which authorises the County Council to take away from the vestry the initiative as to making new sewers, and to replace the discretion of the vestry by its own discretion. I think this view is supported by the case of "The Queen v. the Vestry of St. Luke's, Chelsea," which seems to me to throw some light upon the matter. Mr. Justice Kennedy concurred. Rule discharged.

"New Structure" under the London Building Act, 1894.—Crow v. Redhouse.—Mr. Justice Wills and Mr. Justice Wright gave judgment on July 4th on a special case stated by Mr. Dickinson, one of the Metropolitan magistrates, on an appeal by Samuel Redhouse, under section 150 of the London Building Act, 1894, against a decision by Arthur Crow, district surveyor for the Whitechapel Spitalfields district. The 150th section provides that where it appears from the building notice served on the district surveyor under this Act, that it is proposed to erect any building which may be in contravention of this Act . . . . the district surveyor shall serve upon the builder or building owner a notice of objection, and it gives an appeal to a magistrate from this notice. The case arose out of the following circumstances:—Samuel Redhouse proposed to rebuild a six-story warehouse, No. 3, Church-street, which, in consequence of a fire and of subsequent proceedings, was taken down as dangerous in November, 1894, for more than one-half of its cubical content, so that the proposed rebuilding would be a "new building" within section 5 (6) of the London Building Act, 1894, which defines "new building" as "any building which has been taken down for more than one-half of its cubical content and re-erected, or commenced to be re-erected, wholly or partially, on the same site after the commencement of this Act." A notice of objection was served by the district surveyor on Redhouse. The matters in the notice were, however, remedied with the exception of the objections made to the use, without thickening, of a wall forming the west boundary of the site, as the party-wall between the reinstated building, No. 3, Church-street, and the adjoining warehouse, No. 1, Church-street, the said wall not being in conformity with the provisions of the Act as to new party-walls. Before the fire the party-wall had been the party-wall between No. 1 and No. 3. So far as the party-wall concerned No. 1, which had not been seriously injured by the fire, it had been reinstated in the course of the reinstatement of No. 1. These reinstatements had not amounted to the erection of a "new building" at No. 1. Redhouse appealed to the magistrate on the ground that he was not compelled by law to make the party-wall conform to the provisions of the Act of 1894. The extent to which the party-wall had been burnt and taken down in consequence of the fire amounted only to one-third of its superficial area. The remainder was safe. The party-wall had been erected in conformity with the previous building Acts, but was not of the thickness required by the Act of 1894. In support of Redhouse's appeal to the magistrate, it was contended that, as the party-wall had not been taken down, burnt, or destroyed to the extent of one-half thereof, by virtue of section 208 of the London Building Act, 1894, the proposed use by him of the party-wall was not in contravention of the Act. Section 208 enacts that: "Unless in any case the Council otherwise allow, where a party-wall or external wall not in conformity with this Act has been taken down, burnt, or destroyed to the extent of one-half thereof (measured in superficial feet) every remaining portion of the old wall not in conformity with this Act shall either be made to conform therewith or be taken down before the rebuilding thereof. The surveyor, Arthur Crow, contended before the magistrate that, the proposed re-erection being a "new building" within section 5 (6) of the Act, the party-wall should be so erected as to comply with the provisions of the said Act, and that there was no exemption enacted or implied in section 208. The magistrate thought the contention of Redhouse was correct, and that he could not be compelled to take down, rebuild, or thicken the said party-wall. The surveyor appealed. There being a difference of opinion between the members of the Court, Mr. Justice Wright, as the junior Judge, delivered judgment first. He said: As we are unable to agree upon the proper construction of the Act, I have to deliver judgment first. The question related to a party-wall, and the question is whether it is to be considered as a new structure within the London Building Act, 1894. If this party-wall is considered by itself it has not been pulled down or destroyed to the extent of one-half, and, therefore, if taken by itself, it is not within the section requiring it to be constructed as a new wall. By the Metropolitan Building Act, 1855, section 10, "Whenever any old building has been taken down to an extent exceeding one-half of such building, such half to be measured in cubic feet, the rebuilding thereof shall be deemed to be the erection of a new building; and every portion of such old building that is not in conformity with the regulations of this Act shall be forthwith taken down." If that section is re-enacted in the Act of 1894, either in substance or expressly, the whole of this building comes within it, and must be rebuilt. Now, the Act of 1894 does not in terms contain any such provision. On behalf of the County Council, it was said that the 5th section of the Act of 1894 had that effect. If subsection 6 of section 5 is to be taken according to the usual rules of construction of interpretation clauses, there is nothing in the Act which would apply to the present case. The expression "new building" is not used in those parts of the Act which are material. But is there anything more in the interpretation clause? I think (with great hesitation) that this interpretation clause is an enacting clause, and not a mere interpretation clause. The Legislature could never have intended to destroy section 10 of the Metropolitan Building Act, 1855. But the question is not what the Legislature intended, but what it has done. It is extremely material to observe that this so-called interpretation clause actually does contain one or more enactments—for example, subsection 4 and subsection 7; and to my mind subsection 6 is so expressed that we can come to the conclusion that it is an enacting clause. If the interpretation clause is not to be construed as I have construed it, it seems to me that section 209 would have very little effect at all. I think that Parliament, in enacting the definition clause, did consider subsection 6 of the definition clause as an enactment. Then section 210 appears to me as a mere repetition of sections 7 and 9 of the Act of 1855, and strengthens the ground for concluding that the whole of that group of sections should be considered as included in the present Act. I think the magistrate was wrong. Mr. Justice Wills: It is with great regret that I find myself unable to agree with my learned brother. The expression "new building" is not to be found in the portions of the London Building Act which apply to the wall in question. But I think section 208 governs this case. Supposing that this party-wall had been destroyed to the extent of one-half, the proper course under that section would have been to order the whole to be taken down or to make it conform to the provisions of the Act. It seems to me that, if the wall was not destroyed to the extent of one-half, it is enacted that such liability should not attach. It is said that this case comes under subsection 6 of the interpretation clause. I think there is no foundation for saying that there is a substantial enactment in the interpretation clause. There is a string of expressions which are to have the meanings attached to them. If, therefore, I can find any section which contains the expression "new building," that will meet the present case. Now sections 13, 14, 16, 17, 63, 160, 209, and 210 all contain the expression "new building." It seems to me that the interpretation clause is satisfied by giving the extended meaning to the words "new building" which is contained in the definition clause. I therefore think the learned magistrate was right, and that our judgment ought to be for the respondent. Mr. Justice Wright: My judgment is withdrawn. Judgment for the respondent, with costs.

Successful Appeal against a District Surveyor.—At the Guildhall, on Saturday, Alderman C. T. Ritchie gave judgment in a case in which Mr. Hugh M'Lachlan, district surveyor for the western division of the City, had been summoned to show cause why the decision in his notice of objections in connection with a building, No. 76, Aldersgate-street, should not be set aside. The appellant is Mr. C. E. Lainston, the owner of the building in question. Counsel said that Mr. Lainston was dissatisfied with Mr. M'Lachlan's decision, and he sought to have it reversed. This was the first case that had been heard in the City under the London Building Act of 1894. Before the passing of this Act a magistrate had no power to deal with such a case as this ; but now authority was given whereby he could set aside the objections of a district surveyor. The premises in question were situate in Aldersgate-street, opposite the Manchester Hotel ; the frontage was in Aldersgate-street, and the return in Barbican. Mr. Lainston was reconstructing the building, and in so doing was taking in a very small court at the rear. He contended that by Section 39 of the Act the building was exempt from the requirements of the fifth part of the Act, and, therefore, from the restrictions as to open spaces at the rear of the premises. For buildings generally, the open space or the air-cone was necessary. But where premises were used for offices and counting-houses they were exempt. That was to say, that when premises were in no way used for domestic purposes the air-cone was not required. The appellant had gone to the London County Council with his plans twice, objections being made to them each time, and he now asked for the opinion of the Alderman. As a matter of fact, the alterations now being made would give the whole of the premises more light and air ; but if the recommendations of the district surveyor were carried out, the cost would be out of all proportion. Mr. Percy H. Adams, A.R.I.B.A., 65, Leadenhall-street, put in the plans for the reconstruction of the house in question, stating that there would be no sleeping place in the altered building. Mr. M'Lachlan said there was one matter to remember. The place originally was partly used for domestic purposes. Would it revert back to a dwelling-house? Counsel said, if this were done, defendant could be brought before that court and heavily fined. The Alderman, having reviewed the various parts of the Act, remarked that, believing that under Section 39 such a building was in no way a domestic one, he upheld the appeal, allowing £3 3s. costs to the appellant.

A SEPARATOR PATENT CASE.—DUCKETT v. WHITEHEAD.—This case, which was tried before Mr. Justice Kennedy in February last, and in which Mr. James Duckett, Mr. Alfred Duckett, and J. Duckett and Son, Limited, of Burnley, sanitary ware manufacturers, were plaintiffs, and Julius Whitehead, of Bradford, sanitary pipe manufacturer, was the defendant, came on for hearing of the defendant's appeal against the judgment in favour of the plaintiffs on Tueday, the 2nd inst., before the Master of the Rolls and Kay and Smith, L.JJ. Lord Esher gave judgment for the plaintiff, confirming the decision of Mr. Justice Kennedy. He thought that, comparing the plaintiffs' patent with Sutcliffe's, the plaintiffs' was not the combination of all the same things which were in Sutcliffe's. There was something in the adaptation of the parts in the plaintiffs', which was different from the adaptation in Sutcliffe's ; moreover, that the adaptation of each separate part in the plaintiffs' patent of 1888 was different from the adaptation of all the parts in the plaintiffs' patent of 1887. The plaintiffs had devised a tip which would collect the waste or slops and tip them in such a way that they would fall vertically on to the bottom of the basin, or vertically on to the trap, and so would make the flushing power of that which has to open the trap and go down the pipes much greater than it ever was before. In Sutcliffe's design the chamber and the basin were separated, whereas in Duckett's they were connected, thus causing a certain defect which plaintiffs remedied. Mr. Justice Kennedy's judgment was, therefore, upheld. Lords Justices Kay and A. L. Smith concurred.

NO LIABILITY FOR SANITARY STATE OF FURNISHED LODGINGS.—SARSON v. ROBERTS.—In the Court of Appeal on Tuesday judgment was given by the Master of the Rolls and Lords Justices Kay and A. L. Smith in an appeal from a judgment of Mr. Commissioner Chalmers at Chester Assizes. The action was brought to recover damages for breach of an implied promise that certain lodgings which had been let by the defendant to the plaintiff were fit for habitation. The lodgings were taken by the plaintiff furnished, for himself and family. A few days after they had gone into occupation a grandchild of the defendant, living in the same house, was found to be suffering from scarlet fever. The plaintiff was not informed of this, and continued to stay in the house, and soon after he and his family had returned home his wife and one of his children were taken ill. At the trial of the action the jury found that the lodgings were healthy at the time of the letting, but were not healthy during the time of occupancy ; that the defendant did not inform the plaintiff of the fact of there being an infectious disease in the house ; and that the plaintiff's wife and child contracted scarlet fever from the defendant's lodgings. The learned Comissioner gave judgement for the plaintiff. The defendant appealed. The Court allowed the appeal, holding that it was impossible to read into the contract between the parties an implied covenant that the house should remain in a sanitary condition during the occupancy. The principle laid down in the cases of "Smith v. Marrable" and "Wilson v. Finch-Hatton," that in an agreement to let a furnished house there is an implied condition that the house shall be fit for occupation at the time when the tenancy is to begin, ought not to be extended so as to include such a case as the present. The defendant was therefore entitled to judgment.

SOUTHPORT PIER ACTION.—In the Queen's Bench Division, on Friday, July 5th, Mr. Justice Kennedy had before him the case of the Southport Pier Company (Limited) v. the Mayor, &c., of Southport. This action, which was tried before his Lordship and a jury at Liverpool, was brought by the plaintiffs to recover £500 damages for injuries sustained by the pier in consequence of the rush of water through an outlet or culvert in a new carriage drive. The plaintiffs also sought an injunction to restrain the continuance or repetition of the acts complained of. At the trial the jury found for the plaintiffs, and damages agreed between the parties at £278 1s. 3d. The case now came on for further consideration. His lordship held that the plaintiffs were entitled to the injunction, and entered judgment for them accordingly, with £278 1s. 3d. damages and costs.

A BUILDING AGREEMENT APPEAL.—IN RE THE CADOGAN AND HANS-PLACE ESTATE (LIMITED)—WILLIS'S CLAIM.—In the Court of Appeal on July 5, Lords Justices Lindley, Lopes, and Rigby, gave judgment in an appeal from a decision of Mr. Justice Vaughan Williams, dated April 5, declaring that Mr. William Henry Willis was entitled to prove in the liquidation of the above-named company in respect of a claim arising out of a building agreement entered into between the company and the claimant on the 18th December, 1882. By the agreement in question, underleases were to be granted of the several plots of land delineated on a plan annexed to the agreement for the unexpired residue of a term of 99 years from Michaelmas, 1874, and the claimant was to erect upon the said plots of land dwelling-houses fronting to Lennox-gardens, and stables and coachhouses at the back of such houses fronting to Lennox-mews. The claimant also undertook to pave the roadway to the mews in front of the plots, the work to be done to the satisfaction of the surveyors of the company and of the ground landlords for the time being, and also of the vestry and other proper authorities. At this date Lennox-mews was marked out and roughly formed, although not metalled or channelled. The mews marked out was of the same width and dimensions as at the present time. There was access thereto at one end by Milner-street, and at the other end by Walton-street. The mews at its entrance into Milner-street was not, either at the date of the agreement or at the present time, of the width shown on the plan attached to the agreement, but was less by a small triangular piece of land on the west side of the entrance to the mews, such piece of land being bounded by a wall and used as a back yard to a public-house known as the Australian Arms. The plan attached to the agreement showed the mews to be of a uniform width throughout, and contained no indication either of this triangular piece of land or of the wall by which it was bounded. Prior to the execution of the agreement, a plan, identical with that attached to the agreement, was submitted by the company to and approved by the Metropolitan Board of Works. In pursuance of the building agreement, the company in 1887 procured the grant to the claimant or his nominees of leases of the several plots of land upon which the claimant had erected houses and stables as provided by the agreement. The lease which related to the portion of the mews at the entrance to Milner-street had attached to it a plan which showed the entrance to the mews as it existed in fact—i.e., exclusive of the triangular piece. This lease contained a covenant by the lessee whereby he undertook to maintain or pay for the maintenance of the roadway of the mews until the same should be taken over by the parish or local authority, and the claimant covenanted with his nominee to indemnify him against this liability. The mews was duly made up and paved by the claimant, and an application was made to the vestry to take over the roadway, but the vestry declined on the ground that the mews at the entrance from Milner-street was not of the width shown on the plan approved by the Metropolitan Board of Works. The triangular piece of land in question never belonged to the estate of the company, and the company refused to procure it for the claimant. The result was that the claimant was liable for 99 years from September, 1874, to maintain and repair the roadway to the mews. It was in respect of this liability that Mr. Willis carried in the present claim. The company objected that the building agreement contained nothing imposing any obligation upon them to provide the land for a roadway of the dimensions shown in the plan attached to the agreement. Mr. Justice Vaughan Williams, however, overruled this objection. He held that, though the agreement contained no express words to that effect, the plan, which was clearly incorporated in the agreement, included by implication a warranty that such a roadway could be made on the land of the company. His lordship held, further, that the claimant had not deprived himself of his right to relief by acquiescence or delay. He therefore gave judgment for the claimant, and directed an inquiry, in the event of the parties not agreeing, as to the amount of proof. The company appealed. Mr. Terrell, for the claimant, contended that it was a necessary inference from the agreement that the land in question should be provided by the company, and, therefore, a covenant to that effect ought to be implied. He relied upon the principles laid down in "Knight v. Gravesend and Milton Waterworks Company" and "Thorn v. Corporation of London." The Court allowed the appeal. Lord Justice Lindley said that he was unable to put upon it the construction adopted by the learned judge below. Although it was contemplated that the piece of land in question should be acquired either by the company or by Mr. Willis, he could find nothing in the agreement which bound the company to buy it for the claimant so as to enable him to make a road which would be taken over by the vestry. The appeal should be allowed. Lord Justice Lopes and Lord Justice Rigby gave judgements to the same effect.

CHIPS.

Mr. Hamo Thornycroft's recumbent figure of the late Archbishop Thomson will shortly be placed upon the tomb erected as a memorial to the distinguished prelate in York Minster.

Messrs. J. and J. King, of Norwich, have just completed the painting of a fresco above the chancel arch in the Church of St. Mary Magdalene, Pulham Market. The subject treated is "Our Lord's Ascension," and the figures are life-size. A memorial brass has been fixed beneath the picture, showing that it has been there placed to the memory of members (recently deceased) of the family of the Rev. S. Fellows, rector of the parish.

The Mayoress of Exeter opened on Friday the new classroom erected for infants at St. Sidwell's Church Schools, Exeter. The room is capable of accommodating between 60 and 70 children. The architect is Mr. Jerman, and the contractor Mr. G. E. Saunders, both of Exeter.

At a special meeting of the Ipswich Town Council it was decided to authorise a committee to open negotiations with the Christchurch Park Company for additions to the recently-acquired park of 51 acres. The proposal is to buy the land lying nearest the town, between the Soane-street entrance to the park and the Lower Arboretum, and on which the syndicate now owning the property proposed to build. The corporation offer £960 an acre, having bought the central portion of the ground at £313 15s. ; the syndicate ask £1,125 an acre.

The Rotherham Corporation have applied to the Local Government Board for sanction to borrow the sum of £21,500 for the purchase of land and the erection thereon of police buildings, the purchase of the Mechanics' Hall, and alterations of the municipal buildings. Mr. F. H. Tulloch, M.I.C.E., will hold a public inquiry on Tuesday next.

Special services were conducted in St. Mary's Church, Ross, Herefordshire, on Wednesday week, after relaying of the flooring, to celebrate the reopening of the chancel. Originally the flooring, with the exception of four tombstones near the altar-rails, consisted of plain stone slabs, but these have now been replaced by a vari-coloured marble. The four tombstones have been taken up, and replaced a few inches lower than formerly. In place of the three uneven and worn steps at the altar-rail, there is now only one, three other steps being placed further back. The Communion table has been lengthened by nearly 2ft., and it now rests on a raised ground of coloured marble.

A full-length portrait of Sir Anthony Marshall, Lord Mayor of Manchester in 1893-4, painted for subscribers by Mr. H. T. Munns, of Birmingham, was formally presented to the corporation of that city on the 5th inst. The picture will be hung in the town hall, where portraits of the alderman's predecessors are already displayed.

The council of the Institution of Civil Engineers have reappointed as treasurer Mr. Hugh Lindsay Antrobus, the senior partner in Messrs. Coutts and Co. ; as honorary secretary, Dr. William Pole, F.R.S. ; and as secretary, Mr. James Forrest, who has filled the office for the past 39 years.

At a meeting of committee in Dumbarton, on Friday forenoon, it was agreed to give a commission to Mr. Hamo Thornycroft, R.A., of London, to execute a life-size statue in bronze of Dr. Denny, as also a suitable pedestal for the same. The statue of the distinguished ship-builder will be erected in the burgh of Dumbarton.

Our Office Table.

The unrivalled collection of drawings, etchings, engravings, and prints by the early masters which was formed by the late Mr. John Malcolm, of Poltalloch, and deposited in the department of prints and drawings at the British Museum in 1893, has been offered by its present owner, Colonel J. Wingfield Malcolm, C.B., to the trustees of that institution for purchase at the price of £25,000. It is satisfactory to be able to state that the Treasury, on the recommendation of the trustees, have agreed to the purchase, and a vote for the sum required will be included in the supplementary estimates to be laid before Parliament. No private collection in the world approaches that now purchased in the rarity and value of the engravings and drawings, which number nine hundred, and it is believed by the Museum authorieties that they would fetch at least £40,000 if offered at auction. Among the early Italian works, especially Botticelli's "Study for a Figure of Abundance" and Leonardo's "Head of a Warrior" may be particularised, and many of the German, Flemish, and Dutch drawings are supreme in their classes.

The Prince of Wales presided on Tuesday at a meeting held in St. James's Palace to consider the financial position of the British School at Athens, and described the circumstances under which the school was founded in 1883 and the work that had been accomplished under its auspices under the first director, Mr. F. C. Penrose and his successor, Mr. E. A. Gardner. This work was out of all proportion to the scantiness of its means. While the French School in Athens had an assured income of over £3,000 per annum, and the German School over £2,000, their own school had last year a precarious income of less than £500. Before leaving office the late Chancellor of the Exchequer had taken steps to make a grant of £500, being a portion of the public funds devoted to the encouragement of scientific investigation for the support of the school, which, he understood, the present Ministry were willing to confirm. Several of the Oxford and Cambridge Colleges had voted grants, and the public schools were also moving in the matter. Letters were read from Mr. Gladstone, Lord Salisbury, the Duke of Devonshire, and others expressing sympathy with the object of the meeting. The Duke of Sparta addressed the meeting, expressing the interest which his father, the King of the Hellenes, and himself felt in the work of the school. Resolutions confirmatory of the object of the meeting were spoken to by the Archbishop of Canterbury, Professor Jebb, Sir F. Leighton, Mr. Egerton, British Minister at Athens, Lord Herschell, and the Vice-Chancellor of Oxford University.

A collection of objects found during the excavation of the Temple of Deir el Bahari, brought together mainly by M. Edouard Naville, under the auspices of the Egypt Exploration Fund, is now on view in the rooms of the Society of Antiquaries at Burlington House, W. The remains range in date from the 18th to the 26th dynasty, or about 700 B.C. Some of the exhibits are only to be temporarily in London, and will have to be restored to the Ghizeh museum. There are three mummies and mummy cases of the 26th dynasty, the principal one being that of the prophet of Mentu Zet Thothaufankh. The body was inclosed in each case in three coffins. Many articles of daily life were also found, including knives and hatchets joined to the hafts by narrow strips of skin or leather; boards used for winnowing corn; dolls with the body of a child; little shoes cut into two; rude images and little vases. There are also drawings from the walls of carvings of the "Annunciation" by the god Ammon to Queen Hatshepshu. There is also a representation of the carriage by boat of a huge column or obelisk. A few Coptic antiquities are also shown, including crosses and potsherds.

The question of the additional cost of carrying on works of repaving in the City continuously, and its desirability on the ground of lessening the inconvenience to shopkeepers, was again discussed by the City Commissioners of Sewers on Tuesday, upon the receipt of a report from the Streets Committee, stating that the extra outlay of executing the repaving of Fenchurch-street, Mansion House-street, Poultry, Liverpool-street, and Upper Thames-street, by working during daylight with two shifts of men of eight hours each, between 4 a.m. and 8 p.m., was estimated at £1,257. The accepted tender for working during the ordinary hours from 6 a.m. to 6 p.m., with intervals for meals, was £2,476. The saving of time, if the additional expense was incurred, by working in two shifts would be from five to six days. Mr. Deputy White moved that the work should be done in the ordinary hours, and for the amount of the original tender; and this, after a debate, was carried by a majority of two votes.

The Great Wheel at the Empire of India Exhibition, Earl's Court—a copy of the Ferris Wheel which formed the *clou* of the Chicago Exhibition attractions—is now in working order, having been inaugurated on Saturday afternoon. The wheel was begun early last year, and is built throughout of steel. It has an altitude of 300ft. The axle, which is hollow and 7ft. in diameter, is supported on eight columns, each 150ft. in height. Around the wheel are swung 40 cars, each of which is capable of holding 40 passengers. These cars are 24ft. long by 9ft. wide, and, with a height of 10ft., weigh 5¼ tons each. The design was prepared by Lieut. Graydon, formerly of the United States Navy. The engineer is Mr. John J. Webster, Mr. Basset was the contractor, and Mr. C. F. Hitchens the resident engineer.

A movement was recently inaugurated by the York Philosophical Society for raising a fund for purchasing the properties which now intercept the view of the remaining portions of the ancient city wall of York. The sum of £665 has been raised by subscription, and at their last meeting the city council voted a contribution of £200 to supplement this amount. In addition to bringing into view one of the round towers adjoining Mr. Melrose's property, the two houses at the corner of Marygate will be taken down, and the tower and a considerable portion of the abbey wall will be opened out to view. The street will also be widened at this point. The entire cleared site will be conveyed to the corporation, together with the whole of the walls of St. Mary's Abbey and all the towers. Efforts will be made in the future to prevent any further encroachments on these picturesque souvenirs of feudal York.

At Monday's meeting of the Baths Committee of the Bath Corporation a report was presented by the two members who had been commissioned by the committee to inspect the Roman duct, which has been explored for a distance of 300ft. The report states that here and there, at irregular intervals, it is crossed transversely by massive horizontal stones or lintels, once by a pointed arch, and twice by circular arches. At one point the walls are of very massive masonry. Many of the blocks on their faces being 16ft. by 3ft. The report concludes:—"The absolute uncertainty of what may be the cost of following the duct to its destination—the distance which separates us from the river—the consideration of the further cost of fitting it for permanent service, and guarding against silting up by the action of floods, lead your sub-committee to the conclusion that they cannot recommend any further expenditure upon this interesting discovery." Notwithstanding the plea of the surveyor of works that the work should be prosecuted a little further, the city council have accordingly stopped the work of excavation.

A new and enlarged edition of "Bungalows and Country Residences," by Mr. R. A. Briggs, has just been issued by Mr. B. T. Batsford, with four additional plates, bringing their total up to 39. The volume thus reaching a third edition must perforce supply a want, and certainly several of the designs are picturesquely contrived and conveniently planned with due regard to economic outlay. We have on former occasions favourably noticed this publication, and, as the author remarks in his preface note, we need add no words to what we have already written. A few of the designs have appeared in our own pages; many of them have been realised in execution, and some are to be considered as projected conceptions suitable for country sites. Mr. Briggs has, with no little skill, endeavoured to adapt himself to varying tastes and conditions, so that considerable diversification has been obtained, while at times the work may be described as original and artistically managed.

The last annual report of the Street Department of Boston, Mass., contains a description of some artificial - stonework, which is the first example of the use of this material, on any considerable scale, that the city has yet made. It was put down for a footpath serving to connect two parallel streets about 240ft. apart, but with a difference of level of about 45ft. at the point where it was used. The path is about 138ft. long, and 11ft. 6in. wide. It consists of seven flights of artificial stone steps connected by platforms of the same material, and there is an additional flight of 13 steps at one end. The artificial stone in the walls, steps, and retaining walls cost about 2,123dols. The iron railing and fencework cost about 557dols. The excavation, foundations, stone retaining walls, and wooden fences were furnished by the Street Department, and cost about 2,907dols. The report states that it makes a fine-looking job, and thus far the experience is satisfactory. The contract price for the wall was 36 cents per cubic foot; for the steps, 1·15dols. per lineal foot; for the platforms, 30 cents per square foot; and 10 cents per square foot for surfacing.

MEETINGS FOR THE ENSUING WEEK.

Saturday.—Society of Architects. Visit to Waltham Abbey, where addresses will be delivered by the Vicar, the Rev. F. B. Johnston, M.A., and J. A. Reeve. Train from Liverpool-street Station, 1.50 p.m.

St. Paul's Ecclesiological Society. Visit to Peterborough. Train from King's Cross, 10.15 a.m.

WATER SUPPLY AND SANITARY MATTERS.

Belfast.—A new reservoir is being constructed in the Silent Valley between the Mourne Mountains, and will be completed within another year. This new water scheme will cost Belfast upwards of three-quarters of a million pounds sterling. The catchment area is upwards of 9,000 acres in extent, but it can be added to in the future. It has an elevation varying from 450ft. to nearly 2,800ft. above sea-level, and it consists of high mountain slopes, largely composed of granite and boulders on the surface, free from cultivation, and uninhabited. The Kilkeel river will be intercepted in the Silent Valley, a storage reservoir having an earthen embankment some 520yds. long across the valley, and upwards of 90ft. high over the present river-bed. The top water area will be nearly 250 acres, and the total holding capacity will be 2,850 million gallons of water. The supply will be drawn from this reservoir for use in Belfast through a number of large-geared valves at different levels on the outlet standpipe, which will allow the water to pass through the main outlet tunnel into the main gravitating conduit, which will be formed of concrete, having a maximum carrying capacity of 30,000,000 gallons per day, the size being 5ft. 6in. by 5ft. 6in., and with a regular fall of 18in. per mile. The main conduit will be continued along the mountain slopes to near Newcastle, where it will be carried through Slieve Donard and St. Thomas's Mountains in a tunnel two and a quarter miles in length, with a fall of 12in. per mile, and a maximum capacity of 30,000,000 gallons per day. Some parts of this tunnel will be 600ft. below the surface of the ground. The service reservoir will have a storage capacity of about 80,000.000 gallons, and will be 350ft. above sea-level. While, in 1850, the water for Belfast was obtained from a small place on the Dublin road, in 1865, 1875, and in 1878 further powers were taken to increase the supply, and in 1884 the Stoneyford scheme was adopted, and £750,000 expended.

* * *

In the Queen's Bench Court on Wednesday, before Mr. Justice Kennedy and a common jury, a shoemaker named Gibbons sued Messrs. Mowlem and Co., contractors, for damages sustained by a stumble over a scaffold-pole put down by them round some wood-paving works in Malvern-road, Kilburn, in course of execution by defendants. The jury awarded £40, but execution was stayed.

The Prince of Monaco has sent his physician in ordinary and the head of the Public Works Department to Berlin, to study the hospital system, as he intends to build a hospital for several hundred beds at Monaco.

A committee of friends and former pupils of the late Reginald Stuart Poole has been formed, with the view of erecting some permanent memorial of him, to take the form either of a life-sized portrait medallion or a bust, which might be placed in some building associated with his work.

Among the measures which received the Royal Assent on Saturday were the Great Northern and City Railway (Extension of Time); London County Council (General Powers); Ditto (Vauxhall Bridge); Ditto (Tower Bridge Southern Approach); Birmingham, North Warwickshire, and Stratford-upon-Avon Railway; Manchester, Sheffield, and Lincolnshire Railway; London, Walthamstow, and Epping Forest Railway; and Croydon Corporation and Southend-on-Sea Corporation Acts.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2115.

FRIDAY, JULY 19, 1895.

THE WORKMAN AS A MAN.

THERE must be something very rotten in the state of a country when anybody in it, from the highest to the lowest, is ashamed of the title of "workman." Yet we have lived to see the day when all sorts of affected and un-English names are substituted for it. Sometimes it is Latinised, and then we hear of the "operatives" in the building trade. Sometimes it is avoided altogether. There is no reference to anything so low and degrading as the honest earning of one's own living by labour, and then we get a French term, and are told that John Brown is an *employé* of such-and-such a firm. If this pleases John Brown, he is a great deal weaker in the upper story than we give him credit for being. It is simply a piece of what used to be called in the navy "flap-doodle"—which, as someone explained to Peter Simple, is the stuff that fools are fed on. It implies that the person it is meant to propitiate would rather be thought a useless hanger-on than a valuable member of society. It assumes that he is ashamed of doing his share to keep the world going, and that he wants you to believe his fellow-creatures feed and clothe and provide for him, without his doing anything for them in return.

This, perhaps, has been, and now is to some extent, the lower middle-class idea of respectability. Common people may still be heard to say, "Mr. So-and-So is a gentleman: he has never done anything." It would be more true to say—if this unfortunate being has had his health and the use of his faculties—"Mr. So-and-So is no better than a vegetable: he is what Hazlitt calls a talking potato." Such a creature has never even begun to live; and though he went on to three-score-and-ten, he would only be buried, as Steele says, in the seventieth year of his death. But, on the other hand, it will not do to reckon a man's work by his wages. The highest work is hardly paid at all. It is only by some fortunate combination of genius and independence that it ever gets done. We have all heard of Milton, with his £10 for writing "Paradise Lost." But we do not know how many "mute, inglorious Miltons" may have passed away unknown, because all their time and all their strength were wasted in the daily drudgery without which they could not keep body and soul together. There are all sorts of work wanted in the world—well-paid, ill-paid, and unpaid. Some sorts have to be done by men who get their living by doing them; other sorts have to be done by men who are quite independent of them for daily bread. But this is a mere accident; it is on quite other things that the real honourableness of each class of work depends. It depends on the amount of mind and character which each class of work demands; and the honourableness of each individual workman depends on the thoroughness and skill and success with which his own work is produced.

In what foolish people used to call the "Dark Ages"—because, as some wit remarked, they were so much in the dark about them—this state of things was largely realised. Every workman was proud of his craft; every good workman prided himself on his dexterity in it. The members of the great city companies, whether in London, Chester, York, Coventry, or anywhere else, did not throw off the outward signs of their occupation the moment they left it for the day. They had no false shame about their place in the life of the nation. They would have laughed in the face of anyone who thought to flatter them by calling them "operatives" or "employés." The carpenter was a carpenter, and the mason a mason, and the smith a smith, in season and out of season. Not one of them looked on his work as a sort of degradation—a thing to be done *sub rosâ*, and not alluded to afterwards. Not one of them, when his day's toil was over, and he pulled off his working suit, hastily put on that of some other type of citizen, and said, as he breathed more freely, "Now I'm a man again." The reason was that he never felt so much a man as when he was exercising his skill, his craft, his "mystery." That was what he valued himself, and rightly valued himself on. He did not reckon his own worth, or encourage other people in reckoning it, by the number of shillings per week which it happened to bring him in, and he thus differed—and differed infinitely to his own and to the world's advantage—from his successor, the modern workman.

We have changed a great deal since the 15th century. Much of the change is gain, but not all of it. We seem, for the present, to have staved off great pestilences, as well as great fires. The Black Death has died out; the plague only keeps up a feeble existence in the East; the cholera has apparently met with its match. Great, therefore, is the glorying of the sanitators and the mechanical civilisation mongers. But influenza has lately been as fatal as cholera was in its more recent visits, and medical science is as powerless against it as medical nescience was against the plague of 1665. It defies what to-day passes for sanitation; it attacks by preference the best-lodged, best-fed, best cared-for members of the community. Some new disease may carry the same peculiarities still further. It is quite conceivable—so great is the power which the minutest organisms have of adapting themselves to fresh conditions—that pestilences may arise which can only run their course where what is now imposed on us under the name of sanitation is fairly perfect. Disease-producing germs are already known which can live in fresh water, but not in foul, so that even cleanliness itself, like everything else, turns out not to be an unmixed good. It is earnestly to be hoped that we may be able to retain a pure water supply, and all the other benefits, as far as they are real, which our friends the sanitators have conferred on us. But we had better not whistle till we are out of the wood, and we ought to conquer the influenza before we sneer at our forefathers for not conquering the plague.

On the other hand, the price we have paid for the things which make a modern city differ from a Mediæval one is far from light. We do not refer to the price in money, almost inconceivable though that is. It is the price in the things of the mind—in all that is human, and free and beautiful. The members of the great Mediæval guilds lived in narrow streets—but not in model prisons. They had a house, and not a couple of cells in an "artisans' dwelling. And it ought to be remembered that this very crowding together, which is the thing which strikes us most when we look at the remains of an old city, was not a thing of choice so much as of necessity. If the citizens meant to be safe, they had to build inside the city wall, and so, as the city grew more and more populous, the inhabitants were squeezed more and more closely together. It is not the physical crowding—it is the mental and social liberty of olden times—which makes them worth regretting. "Mental and social liberty!" the reader will reply, if he has been brought up on history as it is now written by politicians, lawyers, and soldiers. "Why, the workman a few centuries ago had no liberty at all. He had no vote—he had no Hyde Park meetings—he usually died in the rank in which he was born." True; but he lived a man's life in it. He could bring out the ideas that were in him; he could develop his own individuality; he was not merely one screw in some great structure, which, when it rusted away, would be replaced in a moment by another screw just like itself. He was not one of 500 "hands" in a shop or a factory, differing no more from each other than 500 bricks, and ordered, when wanted, in much the same way. He was Nicholas the carpenter, or Thomas the mason, or Giles the smith, who, within certain well-agreed on limits, could deal with his timber or his stone or his iron exactly as he saw fit. Each of them, within these limits, could try his own experiments on his work, put his own fancies into it, and get credit for them, when, as it often happened, they turned out to be good ones. So that, incredible as some people may think it, and degrading as it may seem to others, the workman actually rejoiced in his labour. He was not always thinking, as the modern machine-slave inevitably thinks, how he could get his daily slavery shortened to something progressively less and less; because it was not slavery at all, but liberty to him. His liberty had his boundaries—as we have said; whose liberty has not? The greatest architect does not have unlimited sites to build on, or unlimited sums to expend, and his power would very soon leave him if he had. A little bit of material is enough for the highest genius to reveal itself in—a Greek coin often shows as much power as a Greek statue. Pope's poems, written on the little scraps of waste paper, which he hoarded up as if they were banknotes, have outlived libraries full of luxuriously-printed books, where "a rivulet of rhyme meandered through a meadow of margin," and so the little scraps of stonework or woodwork or ironwork in which some artisan of olden times enshrined the best thoughts he had, are worth whole palaces of the modern type—all labour, without love or life in it.

Good people in plenty are doing their best to improve the material condition of the working classes. There is urgent need for it, and we wish them all success. Other good people are trying, in like manner, to raise their mental and moral level. Yet their idea of the way to do this is a rather odd one. They seek to catch the working man when he has done his work. All day long they leave him alone, to grind and be ground in some dismal mill of our soulless, mechanical civilisation. It does not occur to them that anything can be done for him there. But when he comes home at night, tired and worn out with monotonous toil, such as no free man would ever bind himself to for long, they seize upon him. He is lectured and instructed, reproved and exhorted, drilled in classes and evening schools, played to and sung to, and generally treated as a grown-up baby on whom every well-meaning person may try experiments. It is time he was made into a free man again, the essence of whose life lies in his worktime, and not in his playtime. Society will never be stable while human beings are only used as a cheaper kind of machines, and are set to do, from year's end to year's end, nothing but what levers and cogwheels can do as well, or better. We shall yet have to go back to olden times, not for their exclusiveness in politics, not for their oppressiveness in religion, not for their almost unavoidable neglect of many conditions necessary to health, but for the system which made an "artisan" into a craftsman, and a "hand" into a species of artist.

THE AMERICAN ROMANESQUE IN AUSTRALIA.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

IN the palatial Office of the New South Wales Branch of the Equitable Life Assurance Society of the United States there has recently been opened in George-street, Sydney, one of the most noteworthy buildings ever erected in the Australasian colonies, or, indeed, in any portion of the Southern Hemisphere. It is not so much on account of its size that this edifice claims special notice, for there are larger ones in most of, if not all, the Southern capitals; neither is it in consequence of the adoption of the American Romanesque as the style of its architecture, for this has been seen repeatedly in Australia for some years past, not only in important competitive designs, but in buildings actually carried out. The points which commend this remarkable and unique structure to the attentive consideration of architects are rather: firstly, the mode of construction employed; secondly, the extent to which the structural features are made visible and decorative; and thirdly, the dignity imparted to the building by the architectural character of the design. These may be regarded as the purely utilitarian, the utilitarian-æsthetic, and the purely artistic features of the work.

The architect of the building under notice is Mr. Edward E. Raht, the Equitable Society's Chief Architect and Administrator of Buildings, who has already erected for them offices in America, Vienna, Berlin, and Madrid, and who is now engaged in the completion of yet another branch building —that for the colony of Victoria—in Collins and Elizabeth-streets, Melbourne.

The method of construction adopted in the Melbourne building (which is considerably higher than the Sydney edifice, though in my opinion scarcely so artistic in design) is *almost* the style of "steel construction" now so widely employed in America, and of which an example may be cited close at hand, in London, in Mr. J. Wolfe Barry's new Tower Bridge. I say *almost*, since in the Victorian edifice, as I learn from the architect, the objectionable feature of the American method of construction is avoided—viz., the entire disconnection of the inner steel construction and the outer masonry, so that the one stands completely independent of the other on a common foundation The architectural details of this design can certainly not be characterised by the French epithet of *appliqué*, although the only connection between the masonry and the steel constructive work is that afforded by the sliding anchors which permit the extension and contraction by heat and cold of the inner and outer parts to take place without destructive effects. This is an exception well worthy of note, since the local climatic conditions are such that, under a temperature of 105° in the shade, with the wind blowing at the rate of forty miles an hour, the temporary displacement of the continuous columns as they exist in the Melbourne building, of 165ft. in length, would be as much as half an inch—an effect that would certainly be disastrous if showing on an outside covering of masonry, as it doubtless would do if the entire weight of the masonry were "hung" to such movable supports. However, I am glad to be able to record that in the Sydney edifice not even this method of construction has been adopted, since the climatic conditions of this city, and also the lesser height of the building, do not necessitate such a precaution.

The massive façades in George-street and towards Martin-place are of solid trachyte (a volcanic stone of exceeding density and strength, of drab-grey colour, taking as high a polish as granite, and quarried at Bowral, some 82 miles to the south-west of Sydney); while the wall at the rear is of brickwork with trachyte dressings, and that on the northern side is of plain brickwork. The edifice stands upon the solid (drill-tested) sandstone rock on which Sydney is built; the plan is slightly oblong, and the rooms, upwards from the ground floor, are all arranged around inner galleried corridors, which give upon an open quadrangle ceiled with a stained glass skylight and constituting the main hall and staircase. The external dimensions of the building are: Width in George-street, 93ft.; width towards Martin-place, 100ft.; height from the pavement to the top of the cornice, 115ft.; and depth from the pavement to the cellar floor, 19ft. Above the ground floor are six stories, and beneath it is a basement, with cellarage below. The walls of the quadrangle, the divisional walls, and the floors and ceilings are supported entirely upon steel columns and girders, the latter built into the external walls at the points of junction, and within the inner walls the whole construction of the galleries and staircase is of ornamental steel and marble. As far as is possible to human skill, the structure as a whole appears to be completely fireproof; but as every room in an inhabited building is, of course, liable to small local conflagrations, the principle that has actuated the architect (to whose courtesy I am indebted for a mass of detailed information) has been to cover up the metal in such a way as to protect it from the effects of excessive heat wherever there is any possibility of fire, and to leave it completely exposed where there is no such possibility. Thus, in the open staircase and balustrading of the corridors, where there is scarcely an atom of woodwork, the whole of the ironwork is seen, down even to the nut-heads; all the constructional forms being treated ornamentally, with legitimate decorative features added (such as turned, twisted, and other wrought work to the finials and pendants of the newels, the bands of the shafts, &c.), and the whole being finished in aluminium and gold bronze. But everywhere else the supporting columns are incased in terracotta, the fire-resisting properties of which were practically and scientifically demonstrated some time ago in a series of tests made specially for the Equitable Society, at Denver, U.S.A. The weight of the building within the external walls is mainly carried upon eight huge piers so incased (the four more important ones being placed practically at the corners of the quadrangle; and to these the main roof girders are all tied with rollers under their wall ends, to allow for the expansion and contraction under the great and sudden changes of temperature to which these parts may be exposed. The internal walls are composed of hollow terracotta lumber 4in. thick, with $\frac{3}{4}$in. of plaster on both sides. The advantages of this method of construction are, not only that of a minimum of weight, but that these porous walls are fireproof, damp-proof, and sound-proof; they can be cut about, nailed into, and so forth, with a facility unknown in the case of ordinary walls; and they can be removed entirely, to enable two or more rooms to be thrown into one, without the slightest detriment to the stability of the structure. In the construction of the floors, the spaces between the steel joists are filled in with the hollow terracotta lumber, above which, at the level of the upper flanges, is placed a layer of concrete, and upon this a thin bed of molten asphalte, in which is laid, without either screws or nails, a tallow-wood flooring an inch thick. This wood, which extensive municipal experience in Sydney has shown to be the best and most durable of all the Australian hardwoods for the purpose of wood-paving, is cut into 24in. lengths, 3in. wide, and laid chevron fashion; so that a certain amount of pattern in the flooring is obtained, combined with a solidity and durability unapproached by any other mode of flooring I am acquainted with. One other great advantage of this flooring is its verminproof quality, which in this warm climate is very essential.

The steel columns employed throughout the building are those known as the "Phœnix" columns, manufactured, on their special system, by the Phœnix Iron Company, of Philadelphia, U.S.A. The system consists in rolling the shafts in so many sections lengthwise, so as to enable the parts to be examined and tested for flaws before they are riveted together. There may be as many of these sections (from four upwards) as are required, according to the size and character of the columns, and by this mode of manufacture there is a large gain in lightness, security, and strength, but especially in security. The metal used in the staircase and galleries comes from the establishment of L. Mannstaed and Co., at Kalk, near Cologne, where the wrought iron is rolled into decorative mouldings, which can be cut to any length, and are sold by the ton. To these mouldings, put together as a framework, are fixed large slabs of marble for the whole of the plain surfaces; the beautifully veined *rouge royale*, polished on both sides, forming the vertical panels of the balustrading, and Sicilian, polished everywhere excepting the gallery floors and staircase treads (which are simply pumiced), being used elsewhere. The effect of this treatment, which seems entirely novel, is extremely striking, and nowhere more so than in the soffits of the gallery floors and treads, and the backs of the risers, with their fields of mirror-like white marble framed in aluminium-finished steel. Everywhere throughout the building the cornices are hollow, and the soffits screwed up in lengths, and in these are located the horizontally-running gas and water pipes and electric wires, those running vertically being placed in chases in the walls, with cedar coverings, so that they are all readily accessible at any moment. Electric wires are laid to every portion of the building, for the purposes both of lighting and telephonic communication. As regards the former, the pendants and brackets of ormolu, that abound in every direction, are so arranged as to utilise either gas or electricity, or both; while, as to the latter, another novelty is the establishment, by arrangement with the Post Office authorities, of a special telephone exchange for the whole of the building, which is worked from the main hall. Here, also, will be placed a central letter-box, with shoots from every floor, which will be cleared regularly, at stated hours, by the Post Office officials. The fireplaces in the various offices are adapted for burning either gas or solid fuel, and every room is furnished with a fitting of polished cedar, which answers the double purpose of a desk and meter case. Ventilation is amply provided for, the roof around the skylight being fitted with extracting louvres of copper, while, by means of a very simple mechanism beneath every window, the supply of fresh air directly from the outer atmosphere can be adjusted to a nicety. Besides internal Venetian blinds (which are infinitely rarer than they should be in this land of everlasting blinding sunshine), the windows are all fitted (as a protection against fire outside the building) with Clarke's revolving iron shutters, working externally from cases constructed either in the inside cornices or in the thickness of the walls, without the windows having to be opened, while on every story are hydrants ready for instant use.

Passing to the design of the building, the two principal façades of the exterior are constructed of solid trachyte, as has already been said. They stand upon a simple canted plinth, the deeper colour of which, obtained by polishing, imparts to the whole structure an appearance of immense stability. Above this the whole of the walls are rough-hewn, the adamantine stone being worked to a face only in the main cornice, the columns, the string-courses, mouldings, and other subsidiary portions, and further polished in the massive columns of the great front arch, the fifth-floor shafts and the principal fascia. This arch is the most imposing feature of the George-street elevation. Its span is 40ft., and it embraces the ground and first floors of the central portion. Recessed back from it are the main entrances—the central one giving access to the interior of the building, and the side ones to spacious separate offices—and over these are seen the windows of the board-room, in deep shadow. This arrangement has been the subject of some adverse comment; but, apart from the striking effect obtained, the treatment was advisedly adopted in order to secure the maximum of coolness in the board-room during the afternoon, when that apartment would otherwise have been subjected to the scorching rays of the sub-tropical western sun. A plainly-moulded stringing divides the ground floor from the first, while above the latter is the polished fascia bearing the name of the Society in gold letters. Over the great arch now rises a triple arcade, likewise recessed and of exceedingly bold character, taking in the next three storeys, the great divisional columns being of polished red Aberdeen granite, with carved trachyte caps. A corresponding arch, only without the recess, is repeated in each (slightly projecting) wing, but instead of columns we have clusters of four slender shafts, with a continuous cap-like impost worked in a peculiarly simple, but effective, manner out of a single plain block of stone. Above these capitals and imposts is introduced—a little needlessly, I think—the Byzantine dosseret, an architectural feature which, at its best, can scarcely command unlimited admiration. The arcaded stratum of the edifice receives its finish with a bold string-course effectively enriched with nothing beyond one simple decorative moulding; while the story above is treated as an attic, in which the rectangular forms of the abundant windows contrast effectively with the arch-heads below them, as well as with the arcaded corbelling above, which supports the widely-projecting and consoled main cornice that crowns the building. In the façade to Martin-place the treatment of the wings is reproduced in one unbroken length, the non-recessed arcading being of six bays, with columns alternately of polished red granite and tooled trachyte. The design is essentially Romanesque, both as to general character and detail; but there is no slavish adherence either to musty tradition handed down from the "Dark Ages," or to modern precedent as furnished by progressive America. The sturdy, virile; but always artistic spirit of creative adaptation which animated the great builders in early Christian times is everywhere apparent, only directed and modified by that practical common sense without which no *fin-de-siècle* undertaking can command complete success. The selection of the hard, intractable trachyte as the building stone was dictated by the desire to render the structure as indestructible as possible; and while the choice of that material has clearly influenced the character of the design, the design and the material have together given a unique and special impress to this exceptionally striking edifice.

In connection with the exterior, the employment of the sparingly-used sculpture must not be overlooked. This consists simply of an heroic-sized bronze group of statuary emblematic of the "Equitable's" *raison d'être*, and a pair of decorative lions' heads boldly carved in stone on the main cornice. The group portrays a standing female figure of benign and noble mien, protecting with her half-extended arms on one side a lad of may be fourteen summers, and on the other a crouching widow with an infant in her lap; raised upon a plinth, it occupies the centre of the principal façade, between the columns of the arcade and over the great arch. It is the work of Professor Tilgner, of Vienna, and was cast at the Imperial Foundry in that city; and it is creditably distinguished by the success with which the artist, in his treatment, has combined the characteristics of the classic and the naturalistic, both as to pose and costume. The lions' heads, which, as they are some 112ft. above the pavement, are really colossal (though they do not appear so), are handled in a truly decorative spirit, and with a masculine force and *verve* as rare as they are acceptable. They display the able craftsmanship of a young German who has lately settled in Sydney, Herr Kretzschmar, and, though totally different in character from, are, in their way, scarcely inferior to Stevens's exquisite little squatting lions on the standards of the dwarf railings in front of the British Museum, to which, by the way, some similarly sized lions placed a year or two ago as supporters at the foot of the electric-light standards erected in front of the Sydney General Post Office (so noted for its famous "carvings") bear quite a phenomenal family likeness.

The three main portals of the building are protected by outer doors of wrought steel, with external panels of polished trachyte, which are raised to their position at night and lowered in the morning by means of hydraulic machinery. Within these are pairs of glazed swing-doors of polished ruddy blackwood, with handsome mountings of wrought golden bronze, and by the central one of these entrances the vestibule of the "Equitable" building is reached. Standing in the vestibule (which is a veritable gem of architectural dignity and purity), and looking towards the main hall and staircase, the visitor finds himself surrounded on all sides by rich metals and richer marbles, not an atom of wood being visible except the cedar doors and the handrails of the staircase. The walls of the vestibule are arcaded on each side with four slightly recessed bays, the whole being of polished Sicilian marble, except the canted plinth (which is of St. Anne's) and the pilasters and square-cut frieze (which are of the almost opalescent, creamy, and richly brown and indigo-veined *Pavonazza*). The capitals are of dead-white marble, delicately carved in somewhat low relief, as are also the archivolts of the great archway dividing the vestibule from the main hall. The *tympana* of the arcading are filled with mosaics of foliated flat design, in low-toned colours on an ivory-hued ground, and the space above is treated as an attic, the compartments of which are occupied by shield-like medallions of beaten and burnished bronze, of a particular description known in Germany as *tomback*. This *tomback* is likewise employed for the highly-enriched but solidly fashioned wrought cornice and ribs of the twelve ceiling panels, which are filled with polished Sicilian marble slabs. Sicilian marble, pumiced, is used, too, for the flooring, not only of the vestibule, but of the main hall, the staircase, and the open balustraded galleries around, which form the corridors on every story.

Perhaps the most striking feature of the whole interior is the metal and marble staircase, with its galleries, which rises out of the hall, and is specially remarkable for the novel system of construction, already explained. A portion of the ground-floor space, belonging properly (on plan) to the inner quadrangle, is thrown into the great lateral offices, the area of the hall being bounded by screen walls, which take up the line of the gallery fronts above them. These walls are entirely of polished marble, Sicilian being employed for the upper portion, *rouge royale* for the high dados, and St. Anne's for the plinth. The wide white marble stairway rises centrally at the back of the hall as far as the first half-landing, whence it branches out on either side to a second landing, and thence to the first floor. The large square metal newels at the foot are surmounted by columnar standards of similar character, each bearing a bronze-zoned azure globe dominated by the American Eagle with outstretched wings, superbly modelled in fine bronze, and executed at Berlin. The stringboards which support the Sicilian treads and risers—all are framed in steel upon the undersides—are of rolled steel, with decorative mouldings (also rolled) and steel rosettes; and the handsome standards (or constantly recurrent newels) with their artistically-wrought finials and pendants (as well as the framework) of the balustrading, are of similar material and treatment, finished everywhere in mat grey aluminium paint, relieved with mat gold bronze. The panels of the balustrades are of *rouge royale*, polished on both sides, and the effect of the treatment is very strikingly exemplified in the balustrading of the second half-landing, stretching across the open area from wall to wall, above the foot of the stairway, and resting on a flat arch, similarly treated, which spans the space from columns corresponding with the eagle-bearing standards. From the first story the stairs are boldly thrown athwart the open area, in straight and simple flights, from gallery to gallery, till the fifth floor is reached, whence the sixth floor and the copper and tiled roof above it are gained by an ordinary circular iron staircase. The first-floor corridor is arcaded, and the walls of those above are divided out by shallow piers, the whole being finished in light sage green, a plinth of Bleu Belge marble, and buff columns, piers, and mouldings, sufficiently brightened by the capitals with their ornamentation in golden bronze on a vermilion background. Steel-framed slabs of Sicilian form both the floors and ceilings of these galleries, the upper surface rubbed for footwear, and the lower polished for the soffits of the panels. A stained-glass skylight, made in Berlin, ceils the whole, supported upon semicircular steel ribs, with spandrels of finely-wrought open work, the aluminium judiciously enriched with vermilion and gold. The design of the skylight is geometrical, the foliated portions being severely conventional, and the colouring is light and delicate, the most salient tints being blues and greens.

An almost startling novelty to the eye in the "Equitable" building—a novelty, at all events, in this part of the world—is the system on which the passenger elevators are worked. The old boxed-up shafts in which the cars usually run—which are so prolific a source of accident, and which form such draught-creating flues in case of fire—are entirely done away with, and the cars travel noiselessly from the basement to the top story, perfectly free and unconfined, and absolutely without a sound, through the open area of the hall, on either side, upon nothing more than 2in. steel guide-rods attached to the columns of the several gallery balustradings at the two opposite corners of the running space. The actual system of working adopted is that known as the "Waygood high-pressure automatic water-saving patent," in which a very cleverly-designed little valve adjusts the amount of high-pressure water supplied to the ever-varying amount of work to be performed from moment to moment by the cars. Each car is suspended by four steel-wire lifting-ropes, each of which is capable of raising the maximum load of the vehicle, with a factor of safety of 10. That is to say, the four ropes are together equal to the strain of 40 times what is likely to come upon them in ordinary working; while in the event of such an occurrence as the severance of a rope, the "safety gear" is so designed as immediately to grip the steel runners, and so arrest the descent of the car. On each floor above the ground floor a portion of the balustrading of the galleries is prolonged upwards in a kind of angle screen of special design, at the two sides of the angles—one of these having a sliding door—to form the equivalent sides of an imaginary cage to receive the car. On the ground story the treatment is elaborated, so that the three sides form, with the well, a complete cage, and the pair of cages (or "stations") constitute a special and extremely artistic feature of the hall. The whole is of metal and marble, and the lower part alone is solid. The standards and other structural features are of steel, treated like the columns and the newels of the stairs; the lower panels are of polished *rouge royale*, and the upper ones of open and beautifully hammered and foliated *découpé* sheet ironwork, the whole being finished in aluminium and gold bronze. [I here take the opportunity of mentioning that the "Equitable" is the only building in which I have ever seen aluminium used satisfactorily. The success of its employment is attributable, I think, partly to the mellow light prevailing throughout the hall and staircase; partly to the extensive use of the metal, so that it becomes one of the ruling factors in a unique but singularly taking scheme of colour; and partly to the fact that (excepting the great upper handrails of highly-polished nickel, with their big discs, which extend above the whole of the staircase and gallery balustradings, and which, by reason of the polish, the eye instinctively associates with the glistening *rouge royale* marble, and not with the rest of the metalwork) there is nothing else of a metallic nature to be seen, save only the gold bronze, the softness of which harmonises far better than gold itself would have done, with the cool silvery grey—much colder in tone than actual silver—of the mat aluminium.] There being no boxing to the elevators, it is only natural that the cars themselves should be open, as they are. They, indeed, are veritable cages, all of metal, the upper portions being formed of an elegant network of wrought and bronzed steel scrolls, while the panels below the line of the top of the seatbacks are of hammered steel, bearing various devices, and bronzed. The whole design and treatment of the elevators are entirely novel in this country, and are certainly as artistic and successful as they are new.

The first floor of the building is devoted exclusively to the Equitable Society's own business, which is transacted in some dozen or so of separate apartments. That these are all fitted and finished in the very best and most approved manner at the hands of such an institution may be taken for granted, but two portions only demand special notice in a professional journal. These are the general public office and the board-room. The former, 60ft. long by 22ft. wide, occupies a considerable portion of the side to Martin-place; access being gained to it by three sets of semicircular-headed double-swing doors in similarly-shaped screens of ornamented steelwork and ground glass, filling the arches of the arcade. Along the whole length of this chamber extends a counter with an imposing front of *rouge royale*, but the most noticeable feature is the manner in which the separate accommodation for some of the officials of the staff is portioned off. This is effected by massively ornate screens of beaten bronze, of thoroughly architectural character, with richly-pedimented doors and hinged grillgates of wrought-bronze scroll-work opening above the counter. The treatment in such connection is quite novel, and has a very fine effect. The wood employed here for the joinery and cabinet-work is the Australian "red bean," which has hitherto found little use, but seems extremely well adapted to this purpose. Possessing a capital red colour, it is of peculiarly transparent grain, suggestive almost of a cherry-coloured satinwood, and seems to work satisfactorily and take an excellent polish, though I have heard doubts expressed about its standing. Particularly appropriate is the treatment of the board-room, with its quiet richness An elongated octagon in form, the walls, about 12ft. high, are panelled entirely in mat-polished mahogany, with fluted pilasters and ornamentally carved cornice. Above this cornice is a deep cove, enriched with leaf and berry and bold acanthus angle ornaments, finished in cinnamon and gold, while the ceiling is plainly tinted a light greenish buff. The massive marble fireplace and mahogany over-mantel with bevelled silver plate are of corresponding richness, as is also the handsome furniture, set off by a fine Persian carpet.

With the exception of the first floor and the sixth, in the latter of which are the caretaker's commodious quarters and the colossal water-tanks, the whole of the building is designed for letting out to tenants. The four spacious offices on the ground-floor (the two front ones with their own entrances), fitted with strong rooms, &c., and in which marble plays a liberal part, are so designed that they can be tenanted either separately or *en suite*, in which latter case they would be large enough for any bank in all Australia. Beneath them, in the basement, are two very large, well-lighted halls, also with front entrances of their own, and below these again, the extensive cellarage, where is located the elaborate hydraulic machinery which operates, amongst other things, two goods lifts from the back street to the cellars, the gratings in the pavement closing automatically as the machines descend. The second, third, and fourth floors, and a portion of the fifth, contain entirely private offices, admirably planned and fitted with every comfort and convenience that skill and ingenuity can devise; while the whole back of the fifth story is occupied by a banqueting-hall, 91ft. long by 31ft. wide and 23ft. high, which, though undoubtedly a fine and striking apartment, is scarcely so satisfactory from either an architectural or a decorative point of view, as the remainder of the building. On every floor are the most luxurious lavatories. wholly constructed (except the doors and w.c. seats) of polished Sicilian marble, with Doulton's latest sanitary ware and polished nickel fittings. The entire erection of the edifice has been carried out on the excellent and too rarely-employed system of a schedule of prices. and (it must be added) in a manner that reflects the very highest credit upon all concerned.

Speaking of the building as a whole, it may be said that if any failing can be found in the design at which the hypercritical may carp, it is in a perhaps slightly excessive virility, which borders almost on the barbaric. The most prominent instance of this occurs in the very large employment of the ruggedly rough-hewn stone. Were the structure situated in a great open space, the ruggedness would be softened to the eye into mere texture; but, unfortunately, the streets of Sydney are so deplorably narrow, and the authorities are so averse to widening them to a proper extent (even where the opportunity occurs), that the Equitable Society's imposing block cannot be viewed from a sufficient distance to do its noble design full justice.

De Libra.

THE PAYRE COLLECTION OF MEDIÆVAL ART.

THERE can be no doubt about the intrinsic merit and genuine character of the Payre Collection of Mediæval French Wood and Metal Work which has this week been opened to public inspection in the temporary annexe at South Kensington Museum. So long ago as 1888 the Art Department authorities approached M. Payre, a Paris architect and decorative designer, with a view of acquiring his splendid assemblage of ancient craftsmanship; but the terms then demanded by the famous collector long continued at a figure above the available means for such a purchase. It remained for Dr. Middleton to complete the bargain, and the entire collection of Mediæval work has now been bought *en bloc* for about £11,000. From every point of view the transaction certainly has resulted in a valuable acquisition, and notwithstanding the long-continued ill-health of the Art Director, Professor Middleton, it is a fortunate circumstance that he has been able, before leaving London again, to classify and arrange all these exhibits, which are well displayed to considerable advantage in three great alcoves, without crowding, and for the most part the objects are arranged somewhat in a well-defined chronological sequence. The work is by no means limited to ecclesiastical examples, and the collection, which includes between three and four hundred specimens, includes many of a domestic and secular origin, characteristically illustrating the municipal and private life of the later half of the 15th and early part of the 16th century. To the architect and decorative craftsman the exhibition undoubtedly presents an immense fund of suggestive design, while the unrestored condition of the greater proportion of the items forming the collection renders it of the highest value to all students of historic workmanship. The following notes will serve to give an idea of the beauty and varied nature of the objects which M. Payre, with unqualified assiduity and mature judgment, was enabled to get together from all parts of the Continent some thirty or forty years ago. Among the earliest specimens is an iron-bound chest elaborated with 13th-century scroll-work very similar to the famous chest at Chester. Somewhat of later date is the English oak door enriched with two arcades having lancet cusped arches, and a row of quaint grotesques ranging along the centre of the door between the two tiers. The example reminds us how very rare instances of contemporary woodwork of so early a period are in this country, and the screen at Stanton Harcourt, in Oxfordshire, is recalled to mind as typical of that date. The 14th-century carved oak beam hanging in the adjoining gallery exhibits but little advance in figure-sculpture, with the Twelve Apostles forming the subjects for half-length bas reliefs continued in a series of arched niches, after the fashion of a frieze. Hard by is a specially rich 15th-century North French coffer chest. with the front elaborately wrought with Gothic traceried work, and at the other end of the same wall we remarked a Flamboyant retable, with a coved cornice canopy, showing remains of colour on the fretwork cresting above, and ascribed to about the year 1480. Below this last is an ornate 15th-century Fleur-de-Lys North French coffer front, wherein the foliated emblem of the Kings of France has not been so greatly mutilated by the iconoclasts of the Revolution who in some specimens almost entirely eradicated the hated symbol. One or two pulpit fronts are shown. That from Brittany of 16th century date is probably the best, with delicate mouldings worked round the panels in true Mediæval style, and having highly-enriched angle shafts to set off the octagon. Coloured figure paintings still fill the panels of the 16th-century altar canopies, and a painted retable of similar date hangs hard by. The carved-oak Normandy door, with the two grotesque beasts at the base of the upper panel, has foliations freely treated, filling the entire surface with leaves patterned and carved in a way which is almost identical with much of the famous woodwork still to be found in the churches of East Anglia. In the post of honour at the end of the first gallery is a magnificent oak rood, supported by SS. Mary and John. The work dates from the 15th century, and perhaps is quite the finest specimen in the whole collection. The Christ is dignified, and well posed in the majesty of power. The Evangelistic emblems are introduced at the ends of the arms of the cross, which terminate in Fleurs-de-Lys beautifully proportioned. The face of the cross too is filled in with delicate tracery of the most elaborate pattern. Age has given a white colour to the surface of the oak, which makes it assume a mature ivory look at a little distance. In the middle of this gallery is a "money-changer's table," with a folding top and quaint leaf brackets, of primitive design well worthy of observation. The second alcove gallery is divided into two by a composition made up of some panelled inclosures said to have formed a rood-loft entry, very charming in design and florid in detail, somewhat like the work at St. Maclou, Rouen, leading to the western gallery there.* Beside these are several exquisite bits of design displayed, too, on either hand of this exhibit, notably a singing gallery front of Renaissance character, with open fret-cut panels, reminding one of much of Mr. Ernest George's characteristic work. On the other side of the room are two series of pinewood medallion panels, very spiritedly executed with the arms of France and an eagle, skilfully managed, while in another compartment St. Martin is depicted on horseback dividing his coat with the beggar. A wide Late 16th-century door with the Labours of Hercules is a remarkable example of its kind, and should be noted particularly for the exceedingly refined and almost Italian-like frieze which is carved along the top rail below the bas-relief of figures in the arched head. The egg-and-tongue moulding is oddly introduced, and the incongruity of scale in the piece enhances its quaintness. The Brittany fireplace hoods in the third gallery are particularly interesting, and are admirably shown in position. The carvings are crude, but nevertheless are full of vigour and "go." The chairs and tables disposed about are well in keeping with the other 16th-century woodwork, and the sketcher might travel half over France without coming upon anything like such good examples of their kind as these. The cyprus wood coffer of 18th-century Italian workmanship is sure to find admirers for its elaborate figure work in low reliefs, and others will not fail to be attracted by the oak and brass chasse for relics, with a painting on the gabled roof of St. Anthony visiting St. Peter. To our taste the large oak retable, dating somewhere about 1525, and shown in the last gallery, merits a closer study for its refined manner in the Early Renaissance, which followed hard upon the last traces of the Flamboyant Gothic, fragments of which are introduced in spirit, if not in precisely correct detail, over the central niche of this reredos, above the group of the Crucifixion. The panels are divided by columns, and the entablatures are picked out in blue, the whole fabric having at one time been entirely gilded. A very considerable portion of the exhibition is composed of exquisite wrought-iron work—such as Mediæval door-knockers, lock plates and hinges, candelabra and standards, keys, bolts, and steelyards, grilles and panels far too numerous and diversified to even enumerate. No one can afford to let this exhibition pass without taking an early opportunity of examining its contents. Eventually the collection will be divided between the South Kensington Museum and the Art Museums at Edinburgh and Dublin.

THE CLUNY MUSEUM.—III.

By May Morris.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

EMBROIDERY AND COSTUMES.

I WAS rather diffuse in my last paper over the excellency of the tapestries in the long gallery built above the garden and the ruins of the Thermes palace. But I am making no attempt at a connected description of the curiosities in this collection — endeavouring, rather, to give you an impression of the museum as a whole: to render the atmosphere of the place, as it were, more than to describe the objects in it. Here, for example, is the room called after François I., that king having received James V. of Scotland in the Cluny Hotel on the occasion of the marriage of his (François's) daughter to the Scotch king. The great four-post bedstead is richly-carved, and its hangings and coverlet are all of silken embroideries. The whole room, too, is hung with embroidery, pleasant in colour, bold and effective, and well-designed as far as it goes. The ground of these wall-hangings is white satin, showing little of this rather difficult material, however, as the design is full and rich; the bigger subjects have been worked separately in wool, and laid on to the ground, while the smaller ornament is sometimes worked in "long and short" stitches directly on the satin, and sometimes cut out and laid on the ground and edged with cords. The borders are on pale blue satin, and are composed of trophies of arms amidst rich fruits. It is quite a family piece, all in the "grand style" of the 17th century, Henry IV. posing as Apollo; his mother, Jeanne d'Albret, as Venus; his wife, Marie de Medici, as Juno; and his father, Antoine de Bourbon, as Saturn! Each little royalty is graced with his or her coat-armour, symbols and crests, and all the rest of it. Very imposing; but somehow I fail to be impressed, and like best the general result of pretty colour, the rather skilful placing of the ornament, the nicely knotted serpents in the badges, the boldly-drawn wreaths and boughs. Indeed, Henry IV., with his laurel crown and his rays of sanctity, looks something very like a fool, and the various members of his family disporting as the Immortals, little better. The actuality of my lady of the Unicorn, with her genial atmosphere of domesticity and repose, is far more impressive. I am lingering in this little room to cast a glance at the rich, flushed surface of the gilded and painted leather that covers what little wall surface is left by the hangings; to have a good look at the fine 15th-century chimney-piece, with its clear-cut little figures clasping hand-in-hand across the massive stonework, its pot-hooks and hangers and iron supports, all nicely ornamented, and its "dogs" on the hearth, two gaunt figures above Gothic niches, holding the brightly-burning logs together. This chimney-piece—in the 15th century, the days are past when the fire was made on an open hearth in the midst of the hall, some of the smoke escaping by a louvre, or luffer, in the roof above—with another still finer piece, was rescued from destruction in an old house in Le Mans by a local enthusiast. The museum authorities, with the good taste that has distinguished the restorations that were inevitable in this charming old house, have placed the old chimney-pieces acquired at different times about the different rooms for practical use, where they take the place of, and are in much the same style as, the original work. But, linger as I may, I must pass on at last (though from a dim ante-room a glint of armour caught through one of the low, blunt-arched doorways had almost tempted me to wander off at a tangent again), and I find myself in the modest little room known as the room of the "Reine Blanche." Mary of England, sister of Henry VIII., third and last wife of Louis XIII., here spent her time of widowhood in the traditional white mourning robes of the Queens of France. She cannot have mourned very hard, though, for my history-book reminds me that she married three months after his death. Her little room still bears painted decoration of the early 16th century, found under many superimposed layers of wall-paper, medallions, cartouches, garlands, chimeric animals, ruins, all in the Italian style, and done by the ancestors of those clever Italian workmen who still cover wall and ceiling of houses in the peninsula, where the "English style" has not yet penetrated, with brightly-trellised roses, flying birds, and an artificial heaven. In this room, as all over the hotel, there were found, when the modern partitions and decorations were removed, shields emblazoned with the arms of the house of Amboise on the ends of the beams and supports, *paly or and gules*, surmounted by the episcopal cross. The White Widow's room is now filled with lutes and viols and theorbas, and musical instruments of strange elegant shapes; a clavichord, an old Venetian spinet, mellow and golden-brown in colour, a *vielle*, or hurdy-gurdy, a harp with perverse fantastic ornament. The little chapel which leads thence was used in Revolutionary times as a meeting-room for the committee of the quarter, was afterwards turned into a dissecting-room, and finally into a printing-room. A singularly unsuitable choice for all three purposes, being small and dimly-lighted by one high window. It contains various bits of carved work, a 12th-century Christ, the Virgin and St. John from an Italian 13th-century Calvary, and various later Mediæval carvings. The construction of the chapel itself interested me; but as we are not concerned with architecture here, I will not weary you with an amateur description of it. What principally struck me was the central isolated pillar which supports the vaulting of the roof. About the walls are elaborately-carved niches, which, until the end of the 18th century, held statues of the various members of the Amboise family. A round stairway in one corner has a very rich semicircular screen or doorway of stone openwork, and descending the spiral of the stairs one comes out into a little vaulted court, leading round into the garden of the old palace. This court, again, being beneath the chapel, has a central pillar to support the richly-ribbed vaulting, and necessary also for the central pressure in the chapel above. The exterior, as I remember the building (for I forgot to make any notes on this little corner, and have to trust my wretched memory), is fantastic, and Renaissance in feeling. Indeed, the richness of the interior of the chapel, into which the architect obviously put his best work, is less pleasing—and less Gothic—than the simplicity of constructive lines in the dwelling-house itself. There is nothing to surprise one in that, even if the chapel was built at the same time as the hotel, and I think it is contemporary. I suppose that at a period of transition in any art, the humbler work often retains many, if not all, of the old characteristics, while that which is more assertive is up to date, or well to the fore in whatever new character the change of time brings.

I have been trying all this time to get into the two courtyards, now roofed-in with glass, where the textiles and embroideries are gathered together, as well as a fine set of tapestries, the history of David and Bathsheba. And here also are some strange and beautiful scraps of early woven stuffs; silk thin as paper, woven with gold so pure that its sheen is as bright and undimmed as the day it was taken out of the loom; webs so delicate, with slim ornament so daintily drawn that one might imagine the accumulated skill of modern science must be required to produce anything so precious and so fine. Yet we have some idea of the simplicity of the machinery that produced these goods. Modern science prefers to denote its energies in this line to the construction of Nottingham laces and Manchester cottons, while the splendours of the looms of Palermo that enriched the treasures of the Sicilian kings and went out, in their renown, all over the world, seem unproducible by mechanical ingenuity. The tombs of bishops in the 11th and 12th centuries have furnished Persian stuffs of priceless beauty, pontifical garments of solid cloth of gold, with hems and borders flowered with silver roses. But there are objects here of other interest. The Phrygian cap of some Doge Grimani, the white-stitched bonnet of Charles V., the black headgear of an Alsatian woman, the stiff corset of a Venetian—these tags and rags, rescued from among the discarded and dingy trifles of personal attire, strike one uncomfortably, for they are faded, and lamentable, and dead, and retain a grave-like flavour of the vanished personality that graced them living. It is only a morbid and lackadaisical mind that pores over these relics intrinsically valueless, that worships before the openworked stocking or the leaf of a fan once belonging to the Empress Josephine, that eyes with sentiment the garter of Louis XVIII., or draws a sigh over the empty embroideries saved from Marie Antoinette's Trianon.

There is a large case in the further of the two textile courts to which a certain interest is attached. It contains the insignia of the Order of the Saint Esprit, founded in 1579 by Henri III., more for feebly political reasons than for pious ones. There is something coarsely handsome and splendid about this work: rough gold on black velvet and pale green satin. I have found it sufficiently interesting to give as my illustrations a mantle of a Knight of the Order, and a piece of the hanging at the back of the altar. I am inclined to think that it was the colour which first struck my eye. The baldaquins, the altar-hanging or mantle, and kneeling cushion are all embroidered on a pale green satin, the flames gold and silver in raised work. The collar of the Order with its pendent cross is richly worked in the same metals, the arms in the centre thereof being worked in silks and gold. The knotted cord of the collar, with its alternate gold rosettes, makes a very pretty ornament, and the border of the hanging, with Henri de Valois's monogram alternating with the French flower-de-luce, and the gold flames cleverly set about it, may not be a highly intellectual piece of design, but is "not without its merits," as the gentleman said of his lady-love. The fringes, too, are excellent, as, unlike our modern ecclesiastical upholstery as possible, being gold thread carefully knotted by hand, rich and even delicate in effect. The cushions that go with this suite of altar furniture—the "chapel" as it would have been called then—have the dove of the Holy Ghost worked within gold rays, a group which is repeated on the baldaquin alternately with the group of the collar and coat armour. The great mantles of the Grand Master and Knights of the Order are black velvet, closely powdered with the flames, with a broad border of groups of flower-de-luces and Henri's initial wreathed in crowns and trophies of arms. They have broad capes of the green satin ornamented in the same way. To tell the truth, they rather remind me of Lord Mayor's Day in England, and strike a jarring note in the midst of this court filled with rare and delicate fragments, the waifs and strays of a far-gone age. However, the art of really *decorative* embroidery, though degenerating, was not yet lost at the end of the 16th century, and as one's eye wanders round the court it catches sight of a few bits of work so really criminally stupid and quite devoid of decorative quality, that one is fain to be reconciled to the rather theatrical splendour of the Order devised by "Henriquet," the Jester's King.

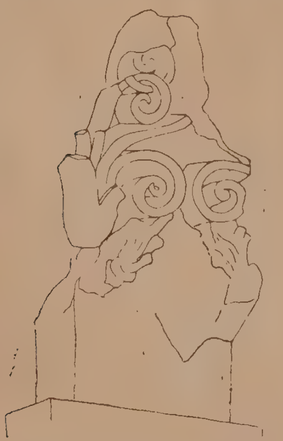
Dearly should I have liked to give some illustrations of a case in this court which has a particular fascination for me, but I have to be content with a few words of description. On the sixth Prairial of the year VII. of the Republic (1796), the remains of Bishop Morard, Abbot of St. Germain des Prés in 996, were brought to light. Whether they laid his body to rest clothed in his best or second-best robes we cannot tell; but they are splendid enough still after the discoloration of many centuries for us to wonder at and linger over. The contents of the tomb were described at the time, and seemed to have been very complete. The skeleton, quite intact, was covered with a large robe of dark violet taffetas. All the seams of this garment were joined by a lace of silver bestarred with gold, a sort of tapestry ribbon very delicate and lovely. Over this was another garment resembling the chasuble of the period. The head, resting on a cushion, was mitred; on the legs were episcopal gaiters of very handsome work, secured below the knee by a cord. The hands were covered with gloves fairly well preserved, and one of the fingers wore a ring with a discoloured turquoise set in the form of a crescent. Some of these stuffs are of the highest interest, and would require a pen better acquainted than mine with the history of early textile weaving to describe them. There is one of Eastern origin made in some tapestry-weaving process; the ground is excessively fine gold, the ornament great Persian letters in blue, interlaced with delicate spiral scrolls of pale pink, a design familiar to us on Early Persian tiles. The tones of colour, though now faded and worn, are most lovely; blue and gold and pale pink, with a thread-like black outline. The quality of the fabric is curiously fine and flat, fragile-looking, and thin as paper.

CLASSIC DETAILS AND THEIR APPLICATION.*

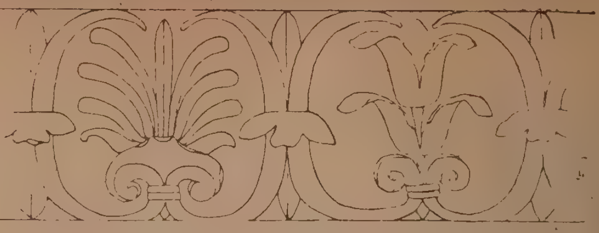
By G. A. T. Middleton.

CLASSIC TIMES: THE ENRICHMENTS.

ALTHOUGH an attempt has recently been made to trace the origin of almost every Grecian enrichment to the lotus-flower of Egypt, it can scarcely be said to be fully proved, and it is probably best to accept most of them as we find them, already perfected like the Orders, when first they appear in Greece. Exceptions to this rule are the anthemion and the guilloche, both of which are found in the Sacred Tree of Assyria, of which there are several examples upon the wall slabs in the Kouyunjik Gallery of the British Museum, dating to about 800 B.C., while there is an intermediate guilloche, in point both of date and of perfection, in the Archaic Room, from the Treasury of Atreus. The Assyrian wall-slabs, too, give clear indications that the Sacred Tree was derived from the palm, which is upon several of them treated in a decorative manner, arranged with symmetrical branches at equal distances apart.



Broken Fragment of Akroterion, Temple of Diana, Ephesus.

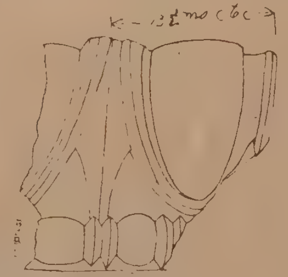


Roman Variety of Anthemion (showing irregularities) from Base of Candelabrum in British Museum.

Broken Fragment of Cornice, Athené Polias, Priene.

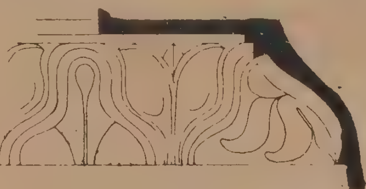
As the Grecian enrichments are almost entirely confined to the Ionic order, and as each is generally to be found in one position only, it is possible to adopt some sort of sequence in their consideration. Starting from the ground-level, we find the guilloche occasionally used upon the rolls of the base, though it is not confined to that position, and is occasionally employed upon a flat surface, as in the example already quoted—the Treasury of Atreus. An intertwining pattern, of which the circle forms the basis, it is adapted for such a position close to the eye, permitting of no deep cutting, and almost best used as a surface-colour decoration only, as is its rectilinear variation, the Greek fret, which was sometimes employed in this way upon the Doric abacus.

Fragment of Lion's Head, Temple of Diana, Ephesus.



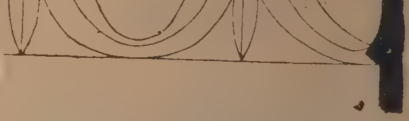
Egg-and-Tongue, and Bead-and-Fillets, Temple of Diana, Ephesus.

Upon the ovolo moulding between the volutes of the capital, and generally where an ovolo-moulding is used, we find the well-known egg and tongue, with generally a bead and double fillet enriching the small roll beneath. The eggs are remarkable both for the invariable beauty of their contour and for the clean finishing which is given to them at all times; rich and graduated shadows being obtained by the equally cleanly-cut eggshell (as it may perhaps be called), and by the tongue.



Leaf-and-Tongue Enrichment, Temple of Mars Ultor, Rome.

The similarly-named leaf-and-tongue is probably but a variant of the egg; but it is employed universally upon a cyma-reversa moulding, and it has been often remarked how well each of these enrichments is adapted to its position, the outline of each being similar in character, though not identical in form, with the contour of moulding which it enriches, and in which it is cut, for it will be noticed that this contour is preserved both in the eggs, the leaves, and the tongues. (See photograph.)



Leaf-and-Tongue Enrichment, Temple of Mars Ultor, Rome.

The cyma recta, which commonly forms the top member of the Ionic cornice, is commonly enriched, as has already been said, with lions' heads, at equal distances apart, forming water-spouts, and between these there is either a scroll of acanthus-leaves and anthemion, or else the anthemion alone in its two variations of honeysuckle and palmette alternately. The anthemion, however, is not entirely confined to this position,

Etruscan Antefix.

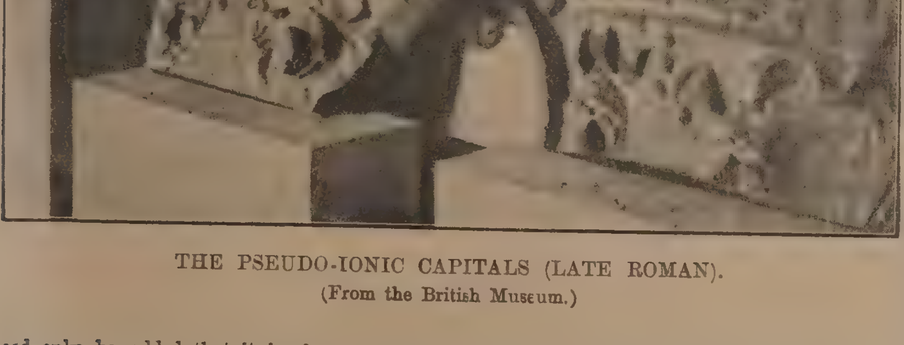
FRIEZE AND CORNICE OF THE ERECHTHEIUM.
(From the British Museum.)

but is occasionally found upon a vertical surface, as at the Erechtheium, both round the neck of the columns and upon the frieze. The photographic illustration of the latter exemplifies two slightly different varieties of the ornament, and shows well the wonderful precision of the workmanship, the beauty of the curves, and the use of only a few principal lines to express the carver's meaning everywhere. The surface curves, too, are restrained and few, adding charm yet scarcely perceptible upon mere casual observation, particularly in the original position of the frieze, far above the eye.

The use of sculpture as an enrichment has already been mentioned; and in this regard it need only be added that it is always confined within proper limits, to embellish the architecture and not to over-ride it, occupying some definite position, as a frieze, or tympanum, or metope, or standing as statuary midway between columns, always framed or in some way cut off from all else, and never on any account mixed up with the conventional foliage ornament of anthemion or acanthus.



THE PSEUDO-IONIC CAPITALS (LATE ROMAN).
(From the British Museum.)

Other enrichments which demand notice are the akroteria and their small relatives the antefixæ—the former being terminal ornaments only, and the latter fulfilling a constructional function. Both are usually devised as variants of the anthemion, in some form or other, as is the deeply-cut and much-destroyed example illustrated herewith, and throughout the best Greek period are always of considerable beauty.

The difference between the enrichments as used by the Greeks and by the Romans is not so much a matter of their form, though the change there is considerable, as in the spirit in which they were applied and worked. The Greeks employed them, with great restraint, to set off and accentuate the beauties of an already beautiful structure; the Romans often, if not exclusively, in a more obtrusive way, in order to draw attention to their own richness and profusion, and to give the effect of lavish wealth. So long as this effect was produced, it seems to have been frequently a matter of comparatively small importance whether the design of each separate part was beautiful, or whether the curve of each individual line was pleasing or perfectly obtained; and as time went on this laxity produced license, and the forms became debased and comparatively crude. Natural leaves and forms of animals were introduced and intermixed, and even in the conventional forms of foliage a crinkled surface became common, destructive of all purity of line.

In these respects the work of the Etruscans, as judged from the cornice recently set up in the British Museum, and from the antefix at South Kensington, is better than that of the later Roman times, and, in fact, seems to be a reflex amongst a less civilised people of the works of the Greeks themselves; and, amongst the Romans, the detail of the earlier period, founded more directly upon the Grecian, and often executed by Grecian artificers, was more pure than that of later date.

Comparing the illustrations of egg-and-tongue, leaf-and-tongue, and anthemion, the change will be at once apparent. Though applied much in the same position as before, the contours of the mouldings, it will be remembered, had undergone a change, and the buildings, too, which they enriched were of a different and more varied character, so that the greater rotundity and voluptuousness is, after all, not to be wondered at, and is, in fact, in many cases more suitable than extreme refinement would have been.

It is natural to find with the debasement of form that the workmanship deteriorated also. The lines are no longer so crisply and so clearly cut, and consequently the few have to give place to the many in order to produce a like effect; and often the setting out is bad, the two sides of a symmetrical ornament being far from coinciding, and the centre-line not truly kept.

As to what happened in the luxurious days of the later Roman Empire, a glance at the pseudo-Ionic capitals illustrated herewith should suffice in place of much description. The idea having become prevalent that the Ionic volute was derived from rams' horns, you find rams' heads used here in their place, and supported, in an æsthetically incorrect way, by yielding crinkled leaves, from which spring scrolls around the bell. Then, from one ram's head to the other there is a large roll, not ornamented by the egg-and-tongue, as in Greece, but by mere surface-carved natural representations of oak-leaves and acorns, and over the centre of this is a human mask. Degradation could scarcely go further, yet it is suitable to its date and to the people who produced it, and was probably, if more were known about it, suitable also to the building to which it belonged, just as were the rich tesselated pavements of the same epoch, adorning the public baths and the houses of the more wealthy of the people, whose wealth was coarseness rather than high refinement or intellectuality.

THE SOCIETY OF ARCHITECTS.

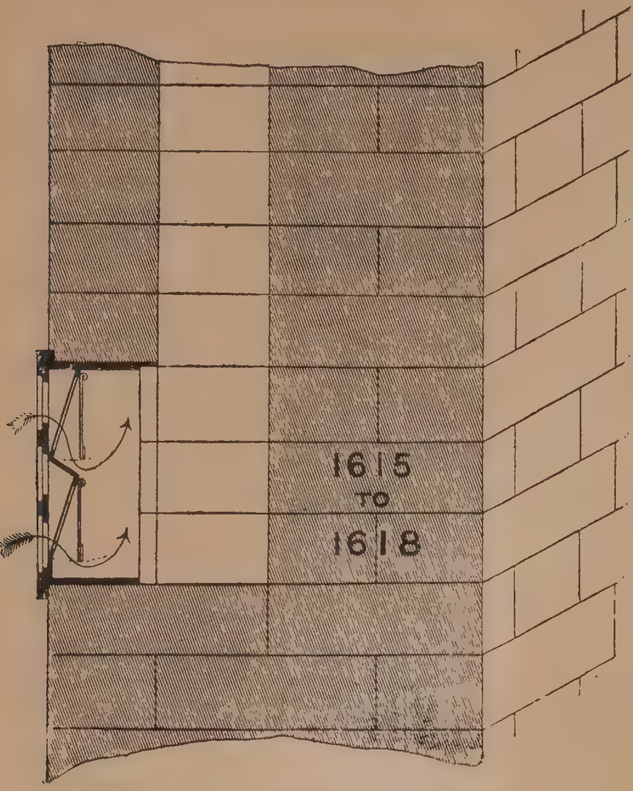
THE tenth ordinary meeting of the Society of Architects was held at Waltham Abbey on Saturday, July 13. The members and their friends journeyed by train from Liverpool-street, and were received at the abbey doors by the vicar, the Rev. F. B. Johnston, M.A., who threw open the buildings for their inspection, and conducted the party to the various points of interest both inside and outside the venerable structure. The society had also the good fortune to include among its visitors Mr. J. Arthur Reeve, who has made a special study of the abbey, and who kindly gave the members the benefit of his researches and conclusions.

In his opening remarks he stated that the party were assembled in what was the nave of the original church. The eastern portion, containing the crossing, the transepts, and the choir, together with the conventual buildings, had disappeared at the Reformation. There were two small fragments of the latter buildings remaining—viz., a vaulted passage, which apparently gave access to the cloister court at the N.E. angle, and a portion of the abbey gateway.

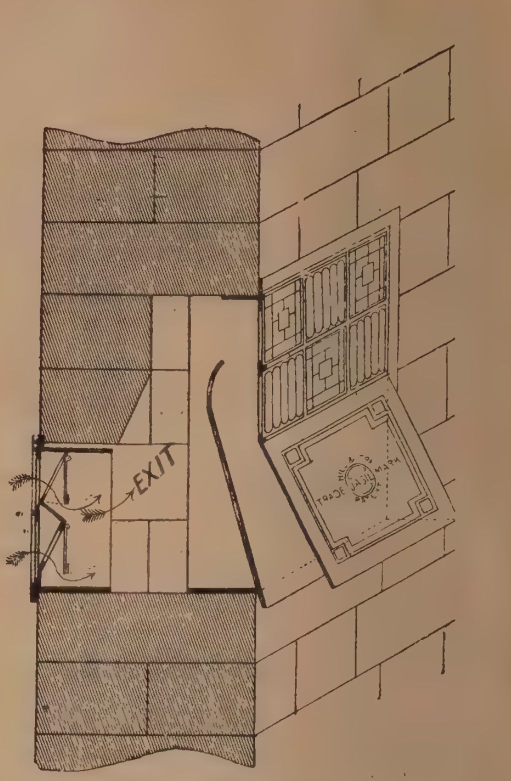
We will now (said Mr. Reeve) proceed to the discussion of the Abbey Church itself. The point of the controversy, in connection with Waltham Abbey, has always been as to whether any portion of the existing building was erected by Harold, or not; and, for some years past, it has been my constant endeavour to show that not only some fragments of his work remain, but; in fact, that the greater portion of the church, as we now see it, was executed by him; and I cannot help thinking that I shall be able to put some facts before you this afternoon which will prove to you that there is a great deal of evidence in support of this theory. It is, moreover, evidence of the very best type, because it is derived, in the first instance, from the building itself, and it is upheld by all the documentary evidence which, as far as I am aware, is in existence. It would take up too much time if I were to discuss this documentary evidence now. I will, therefore, only say that the chief *positive* point in it is that it establishes the fact that Harold did build an abbey here, and that it was looked upon at the time of its erection as a building of extraordinary magnificence. It was probably consecrated in 1059 or 1060, and it was thus raised concurrently with Edward the Confessor's Abbey, at Westminster; its dimensions, however, must have been considerably less, and, consequently, it took a much shorter time to build. But for Harold's church to have been accounted a structure of great note, it is clear that it must have been at least as fine, as far as general treatment is concerned, as Westminster. In discussing this most interesting question it should be borne in mind that as both Harold and Edward had spent a considerable amount of time in the Norman Court, they must have been well acquainted with the style of architecture which was practised there; and both being men of culture, it is impossible for them not to have been much impressed with the grandeur of the Norman buildings. It may, then, be taken for granted that when these two men determined to erect abbeys of very large dimensions, they would gain their inspiration directly from Normandy; and hence there can be no archæological absurdity in attributing a building such as this to a period anterior to the Norman Conquest. I do not, therefore, attach any weight to the arguments which one hears brought forward very frequently as to the impossibility of work of this type having been done in England before the Conquest; there can be nothing *impossible* in it when we take into consideration the two facts—first, that it was being practised at this period in Normandy, and second, that the connection between the English and Norman courts was most intimate. Edward the Confessor was even more Norman than English in his tastes, and he showed his strong predilection for the countrymen of his mother by granting lands in England to many Norman nobles, and it is an historical fact that these men raised castles upon the territories thus acquired. The English of the middle of the eleventh century were, therefore, distinctly in touch with Norman ideas; and hence I argue that for a man like Harold to decide to build a Norman church in England was nothing more than might have been expected; it was merely a bold stroke on the part of a bold man, and it was certainly eminently successful; at all events, it always seems to me that there is something in the proportions of Waltham Abbey which raises it above most of our Norman churches, even in its present curtailed and mutilated state. The theory which, as I believe, accounts for all the phenomena we find here, is simply this: that from the west wall, up to and including the second pier from the east end on both sides of the nave, we have Harold's work—perfect on the south side and perfect on the north side up to the string course below the clerestory; that the two eastern bays, together with the western arch of the original central tower and the remains of the south transept were erected by Henry I. during the lifetime of his first wife, and that the clerestory in the western bays, on the north side of the church, was probably reconstructed by him after his second marriage. The 14-century alterations in the western bays are too palpable to require special notice at present. Let us now consider in detail the evidences which exist in support of this theory, and first allow me to point out to you some of the differences which obtain between the work to the west of the second pier from the east end, and the work to the east of the same, because it is clearly of importance to prove that a change of style actually does take place at this point. In the first place, the whole of the western work is executed with very fine joints, while the eastern bays are jointed throughout in a very coarse manner. It was, I believe, Professor Willis who first called attention to the fact that the jointing of Norman work differed greatly at different periods, and he laid it down as a rule that wide joints denote Early work and fine joints Late work. That such is the case at Canterbury, in connection with which, I believe, he formulated this theory, I have no manner of doubt; but I am certain that those archæologists who have based arguments in connection with the sequence of dates at Waltham Abbey on this theory, have been led into error, owing to their not having given due attention to all the phenomena which exist here; but of this more presently. Another difference is found in the section of the bases: In the western bays the mouldings consist of a shallow hollow and a shallow roll, with a fillet between—the simplest form of all Norman bases; in the eastern bays the mouldings are also shallow, and are of two kinds, those to the respond having a second fillet and a roll added above the hollow, and those to the circular pier having two shallow hollows above the lower fillet and roll. The bases to the nook-shafts of the aisle windows in the two portions of the church also differ from each other in a corresponding manner. Next we come to the capitals of the nave piers. Throughout the western portion of the church these are composed of two courses, while in the eastern bays they are executed in a single course; the abacus mouldings also differ, the western ones being simpler than the eastern*; and here again corresponding variations occur in the aisle windows. The capitals to the responds at the eastern and western ends of the church present another point of difference; in the latter, both the main cap which takes the soffit arch, and the side caps are of the same depth, while in the former the main cap is about 2in. deeper than the subordinate ones. Another change takes place in the manner of working the chevrons on the inner voussoirs of the nave arches. In all the western arches they are worked up and down on the face, and they show very slightly on the soffit, whereas in three of the eastern arches they work up and down on a splay, and in and out on the soffit, and in the fourth they are very similar, working up and down on the face, and in and out on the soffit. The chevron mouldings in the eastern bays are slightly richer in section than in the western bays, and the mouldings in the western arch of the original central tower are very similar, both in section and in working to the eastern arches of the nave. The space between the labels at the springing of the eastern arches is filled by a roughly carved head—no such ornament obtains at this point in the western bays. There is a marked difference between the eastern and western triforium piers on plan, the former having three semi-columns to carry the arch, one towards the nave, one in the centre, which took the soffit arches now lost (for I cannot agree with Mr. Freeman that these never existed), and one towards the aisle; the latter have only two, one towards the nave and the other in the centre. The clerestory also differs greatly in the two parts of the church: in the western bays the columns are built up in courses, and they consist on plan of a cluster of four shafts, between which the points of a star project, while in the eastern bays the columns are monoliths, and they are alternately polygonal and circular on plan, and they are interchanged on the two sides of the church. The sculpture, such as it is, indicates two different dates; the heads, which form the terminations to the pseudo-vaulting shafts in the western portion of the church, are rounded in profile, while those in the eastern bays are square; they are all heads of men, but the former are represented as being quite smooth, whilst the latter have moustaches, and they are also embellished with leaves of early Norman character, the stalks of which start from the corners of the mouth and twist round, so that the leaf itself is made to cover the ear. Other minor differences exist, but I will not weary you by enumerating them all. I will merely call your attention to the structural evidence of a change of date, which is provided by the great irregularity which exists in the jointing above this second pier from the east end, from the sill of the triforium to the ceiling. Now, all of these variations taken together, although many of them are slight in themselves, do conclusively prove that a change of date does take place at this second pier; the next point to be decided, therefore, is, which is the earlier, and which is the later part of the church? A casual observer would unquestionably be inclined to answer this question by saying that the greater roughness and coarseness of the two eastern bays prove that they must be older than the very refined work which we find throughout the western portion of the building; and yet I can place evidence before you which I believe you will admit proves in the most incontrovertible manner that the western part of the church is the older, and that being so, it must also, without the shadow of a doubt, be the very work which was executed by Harold 830 years ago. I have already mentioned the extremely thick jointing of the eastern bays; you will see that this continues right up the jambs of the western arch of the original central tower, and through the arch itself. We may, therefore, safely assume that this archway is of the same date as the eastern bays; but this is merely indirectly interesting. What is of far greater importance is that the jointing of the archway at the east end of the south aisle is of exactly the same character, and all the joints run through in level courses from the jamb of the tower arch, right round the respond of the nave arcade, to the jamb of the aisle arch. It is, therefore, impossible not to believe that the whole of this work was done at the same time. But, strange to say, when we come to this arch across the east end of the aisle, we find an entirely new type of detail introduced, for the chevron ornament is altogether discarded, and very fully developed running mouldings of twelfth century character are substituted—mouldings which I think you will all admit cannot well have been executed before the year 1100. It is also extremely interesting to observe that mouldings of precisely the same character exist on the inner arches of the only two remaining windows belonging to this period, one of which is in the easternmost bay of the south aisle, and the other is in the west wall of the south transept. In other respects, the arches of these windows correspond with the western windows. We have it proved, therefore, very clearly that these two eastern bays of the nave arcade are associated with well-developed running mouldings, which must belong to the 12th century period, whereas throughout the western portion of the church no sign of any such running mouldings is found; certainly, there is a very shallow bead moulding on the edge of the triforium arches, but this is by no means capable of comparison with the mouldings just described; it is nothing more than might easily have been executed with an axe wielded by the hands of a skilful man. As already mentioned, the doorway towards the western end of the north aisle possesses running mouldings, but the jointing of the internal jambs of this door clearly shows that it has been rebuilt. The foregoing evidence is very strong, but there is even a stronger and a much more curious piece of evidence to be described. It will be observed that this second pier from the east end, to which allusion has already been made, has been rebuilt; this work was carried out under the late Mr. William Burges, A.R.A., in 1860, in which year he was called in to report upon the Abbey, and afterwards to carry out the works of restoration which were required. Now, when Mr. Burges inspected the building, the first thing, naturally, which struck him was that this pier was in a most dilapidated condition. It had been grievously cut about above the floor of the church, and owing to various interments which had taken place beneath the floor, it was found that the foundations of the pier had been almost entirely destroyed; consequently, it was, of course, found necessary to reconstruct the pier, and this was done in the most careful manner possible. The arches resting upon it were first strutted up according to advice given by Mr. Burges' father, the well-known engineer, and when the whole of the weight had thus been properly supported, the pier itself was taken down, and it was rebuilt upon a strong new foundation. So perfectly was this work carried out, that not a stone of the superstructure was disturbed when the struts were finally removed; therefore, although this pier has been rebuilt, from the top of the abacus moulding upwards, we have the work in its original condition, with the few exceptions which are apparent where new stones had to be inserted owing to the old ones being in too bad a state to be left. I have mentioned this act of rebuilding simply to meet any objection which might be raised to my argument on the score of the present state of the walls having been produced by the works which were carried out in 1860. Anyone who had studied these bays as carefully as I have done would know from internal evidence that the settlement which runs right up through the third bay from the east end must date from a period anterior to the reconstruction of the pier; but it might possibly occur to the mind of any archæologist who had not gone very minutely into the matter, that the settlement was of late development, and therefore I have thought it well to mention in the first instance that it did exist exactly as we now see it before 1860; of this there is not the shadow of a doubt. It is upon this settlement that the argument in favour of the western portion of the abbey being Harold's work is chiefly based. When I came to measure these two bays with a view to settling, if possible, the question as to the dates of the two portions of the abbey (my drawings to a scale of half-an-inch to a foot are now in the library of the Royal Institute of British Architects), the first thing which I discovered was that the springing line on this second pier is 9in. lower than it is on the piers both to the west and to the east; this, therefore, proved at once that the pier in question must have sunk bodily into the ground to that extent. Now, a settlement of this magnitude is almost certain to take place immediately after the erection of the building; at all events, if we give it fifty years to develop itself, it is quite as much time as ought to be assigned to it. No doubt, if you carefully cut away the foundations of a pier during any portion of its existence, you can make it settle down; but if this be done the settling down is extremely unlikely to be suddenly arrested, as was evidently the case here. Let the foundations of any of the piers of this church be sufficiently destroyed to cause the work to begin to move, and you will find most probably that it would take considerably less than fifty years to bring that portion of the church to the ground. When, therefore, a settlement of this description takes place bodily without the total collapse of the superstructure, you may be tolerably certain that it occurred shortly after the erection of the building, and that the pier or wall went down until the foundation came to a hard bottom. Naturally, as soon as I discovered that this pier had sunk to this extent, I saw that it accounted for the settlement in the arches and wall above it, which is so apparent all through this third bay; it proves clearly that they were all resting upon the pier when it went down. But the extraordinary point is that none of the arches on the eastern side of this pier are similarly affected; the joints of these arches are as true as they were when they were first made, and this notwithstanding the fact that they all spring from a lower level on the west side than they do on the east. Now this incontrovertible fact appears to me to be as conclusive evidence that the arches in the second bay were built after the pier went down, as the crippled condition of the arches in the third bay is that they were built before the pier went down. Further, the string-courses in the third bay and throughout the western portion of the church are jointed in stones of considerable length, and in this third bay the joints are badly broken. This is quite apparent from the floor of the church; but in the second bay these string-courses are jointed in peculiarly short lengths, and they are brought gently down from the higher to the lower level without any break whatever. It is also a curious fact that the course of ashlaring below the string-course between the clerestory and the triforium comes to a feather edge on the eastern side of the arch, not by the arch rising to the string, but by the string coming down to the arch. The condition of the clerestory columns is also significant. In the second bay from the east end they are both vertical, although the western one stands on a lower level than the eastern one. In the third bay, however, they are much out of the perpendicular, and the eastern one, as might have been expected, being more directly over the point of settlement, is considerably more crooked than the western one. To recapitulate, then, we have these facts to deal with:—First that evident differences do exist between the architecture of the five western bays and the two eastern bays, the two latter are clearly associated with the western arch of the central tower, and with the distinctly advanced Norman mouldings at the east end of the south aisle; these much later mouldings also occurring in the remains of two blocked-up windows, one of which stands in the eastern bay of the south aisle, and the other in the west wall of the south transept; the association of all these features—namely, the two eastern bays of the nave, the western arch of the great crossing, the arch at the end of the south aisle, and the two windows—being clearly proved by the particular type of coarse jointing which is found in all of them, by the joints of the south-west pier of the central tower running through in unbroken courses to the jamb of the arch at the east end of the south aisle, and by the profile of the mouldings of the capitals and bases. We also find that the second pier from the east end sank 9in. into the ground after the bay to the west of it was erected, and before the bay to the east of it was built in its present form; and I am certain that if you give due consideration to all these facts, you will be brought to this conclusion—namely, either that the five western bays of this church, as we now see them, were erected by Harold, or else that Harold's church was entirely destroyed, and afterwards rebuilt by William the Conqueror or by his son, William Rufus, before the great works undertaken by Henry I., or more properly speaking, perhaps, by his two queens, were put in hand. But I can hardly suppose that anyone can consider the latter of these two alternatives more probable than the former; for myself, at all events, I am bound to say that the evidence is as conclusive as could be wished, that the western part of the church was built by Harold. In the first place we know that he was well acquainted with Norman ideas, also that he built a magnificent abbey on this spot, and that, in all probability, he was buried here. We also gather from history that William the Conqueror did all in his power to stamp out the memory of his predecessor on the English throne; and it is on record that he treated the canons of Harold's foundation with terrible harshness, robbing them of the chief part of the movable wealth which Harold had bestowed upon them. Therefore, it seems most improbable that he would have taken the trouble to rebuild the one building in England which was more associated with Harold than any other, and in which early tradition says his body was laid. He could not have done so without rendering marked honour to his hated rival, and this seems the very last thing he would have been likely to do. William Rufus, being the man he was, is even less likely than his father to have erected such a building as Waltham Abbey. Moreover, he also is specially mentioned as having inflicted wrongs upon the society; it seems impossible, therefore, not to agree with Mr. Freeman when he says that "no one can attribute the rebuilding to their times"—that is, either to William the Conqueror, or to his son Rufus. Thus, then, I am forced to the conclusion that a large portion of Harold's church does stand, and that the eastern bays of the existing building were re-erected by Henry I., in conjuction with the great works which would seem to have been undertaken by him in connection with the choir. Doubtless it is a curious fact that while dealing with the nave Henry I. should have assimilated his work to that of the older portion of the church; but at the same time several other cases where the same thing was done can be cited; and that it was done here, and done, moreover, in the most intentional manner, is clearly proved by the existence of the moulded arch at the east end of the south aisle, and no doubt the whole of the choir and transepts, as far as they may have been built by Henry I., were carried out in the same advanced style. The western portion of the north clerestory furnishes another very marked example of an earlier type of work, having been executed by a man who would naturally have employed a later style, for the distinct purpose of making his new work assimilate with the older surroundings; but whether it was done by Henry I., Stephen, or Henry II., is perhaps doubtful. It was, however, certainly not done at the same time as the rebuilding of the eastern bays of the nave; and it seems to me rather more probable that the east end of the nave was rebuilt during the life of Henry I.'s first wife, and that the north clerestory was reconstructed during the life of his second wife—for we know that Waltham Abbey became the property, first of Maud, and afterwards of Adeliza, and that they both took great interest in its well-being. As to the choir of Harold's church we know practically nothing, but presumably it was very short. I should be inclined to think there was a transept, with possibly one bay to the east of it, and very likely the church terminated in a semicircular apse. An argument against the church having been built by Harold, as we now see it, is sometimes found in the fact that the western portion has been preserved, because people say that Harold would have begun at the east end, and that he would probably not have completed his church westwards before his death; but this assumption is based upon the supposition that Harold's choir was very long, of which, however, we have no evidence, and it is more reasonable to suppose that it was short; and if so, the whole church might easily have been finished by the founder. Foundations of a large choir do unquestionably exist, but these must have belonged to the work of Henry I. and Henry II., and possibly also to a 13th-century extension; for it is recorded that a re-dedication of the church took place in the year 1242. This probably indicates that the choir was lengthened at this period, and that in consequence the high altar was moved eastwards, thereby rendering a re-dedication desirable: possibly even it might be spoken of as a consecration of the new presbytery. It appears from the foundations which have been discovered that the eastern portion of the abbey church was quite as long as, if not longer, than the existing nave. The design of the west end of Harold's church is almost as uncertain as the form and extent of the choir, but perhaps it is reasonable to suppose, from the treatment of the westernmost bay on both sides of the church, both internally and externally, that the aisles were intended to stop against western towers of small dimensions; for the first piers from the west end are considerably larger than any of the others, and the aisle walls in these western bays are thickened out in just such a manner as might be expected, if they were intended to form the bottom story of western towers, such as Harold would have been likely to build. Added to which, clerestory windows never existed in these bays. It is, however, very doubtful whether these towers were ever erected, and certainly if they were, they have left strangely slight indications behind them. The roof of Harold's nave was of wood, the pseudo-vaulting shafts went up and ended in a capital above the top of the clerestory arches, and the necking of one of these capitals is visible below the present flat ceiling. No doubt heavy beams spanned the church at each pier above these capitals; but whether the ceiling above these beams was flat or barrel-shaped, there is, as far as I am aware, no evidence to show. It is, no doubt, difficult to believe that the aisles of Harold's church were vaulted in stone; but certainly a very definite leaning towards such a treatment did exist, for there can be no question that the vaulting shafts at the back of the piers of the nave arcade are original, and the marks of the corresponding piers against the walls are also plainly visible. Evidently, therefore, transverse ribs of heavy form must have been thrown across the aisles, and if any evidence could be found to suggest that an ordinary Roman vault formerly existed between them, I should not myself hesitate to accept it as

---

* The capital and base of the first pier from the east end on the north side of the nave are similar in all respects to the work in the western portion of the church, but it seems probable, nevertheless, that this pier was rebuilt when the eastern bays were reconstructed.



APPLIED TO AIR SHAFT.



APPLIED TO EXTERNAL WALL.

part of Harold's design.* But perhaps it is more probable that the space between these transverse arches was covered with a flat wooden ceiling, the back of which would have formed the floor of the triforium. Mr. Freeman seems to think the aisles were always open up to the triforium roof, but herein I can hardly agree with him. But whatever form of ceiling may have existed here would seem to have been removed, together with the transverse arches, in the 14th century, when the large alterations to the church were commenced, which fortunately did not extend further than to the second bay from the west end. The man who devised this alteration must have been a very poor sort of architect. His intention was to have thrown the nave arcade and the triforium into one composition, but what he hoped to gain by this treatment it is difficult to imagine. It was certainly not a complete renewal of the design which he contemplated, for he retained the piers of the arcades intact, and by inserting a pointed segmental arch in place of the original triforium arch he introduced the ugliest feature which Gothic architecture ever gave rise to. The most charitable view to take of this work is to suppose that it was undertaken by a madman. Some people think that this work was done by the same man who designed the original 14th-century west end. For my own part, I can scarcely believe that the man who conceived the grand composition of the latter could possibly have perpetrated such an abomination as the former; but undoubtedly the two works were nearly contemporaneous. Unquestionably the 14th-century west end must have been very fine; the south-west and north-west buttresses terminating in massive octagonal pinnacles, being specially worthy of note. It is probably needless to mention that the existing tower was begun in the reign of Queen Mary, and clearly it was built out of fragments of the ruined monastery. Old prints are in existence showing the tower with a battlemented parapet, which presumably proves that Queen Mary's Tower was probably so finished originally; but the upper part having fallen into a state of decay, it was refaced, if not entirely rebuilt, about 80 years ago. This work, as far as the belfry stage is concerned, was done entirely in clunch, and it is now again in a most dilapidated condition. The Lady Chapel is an extremely interesting piece of Later 14th-century work. Mr. Burges once suggested that perhaps it was designed by the man who executed the 14th-century work at the west end during the latter years of his life; and this seems not at all improbable. The chapel was very carefully restored about fifteen years ago by Mr. Burges, and the wooden screen across the arch between the chapel and the south aisle of the church was executed from my own designs, after his death, as a memorial to the late vicar. The composition in the centre represents the arms of the Abbey. Originally, the tracery and arches of the windows in this chapel were executed in clunch, and they had all fallen into a state of decay long before the restoration was taken in hand. Of the side windows no fragments even of the tracery remained, but enough of the large square-headed window at the west end was left to make an exact reproduction of the design possible; and the inner plane of tracery in this window is entirely ancient. The external facing of the chapel is worth looking at; it is a very good piece of 14th-century ornamentation, produced by means of alternating bands of stone, squared flints and bricks. At some period in the 13th century a violent quarrel took place between the monks and the townspeople, which resulted in the complete separation of the choir and transepts from the nave, by the erection of a solid stone wall across the lower portion of the western arch of the lantern; and, I presume, corresponding walls were continued across the archways at the eastern ends of the aisles. The original work remains across the east end of the nave, below the new end put in by Mr. Burges, and the two blocked-up doorways on each side of the altar may be seen on the outside. I believe I am right in stating that this wall was the practical result of an understanding, which was arrived at between the contending parties, to the effect that, from the period of its erection, the portion of the church to the west of the barrier should belong to the parish, while the eastern part should appertain exclusively to the monastery. This division of the church may possibly account for the erection of the existing Lady Chapel in the somewhat peculiar position in which it stands. No doubt there existed an altar, dedicated to the Blessed Virgin, in the eastern portion of the church, from which, after the division of the building, the parishioners would have been cut off. Hence they would naturally desire to have a Lady Chapel of their own, and, presumably, the site chosen was the most convenient position for the noble building which they were anxious to erect.

At the conclusion of Mr. Reeve's remarks, a vote of thanks was proposed by Mr. Lovegrove, and seconded by Mr. Mallet, and supported by Major Leslie and others, to Mr. Reeve for his services, and also to the vicar for throwing open the church. The party were then conducted to the various objects of interest, both inside and outside the building, including a small stone bridge across a stream to the N.E. of the abbey, of 14th century date, having a flat elliptical arch supported by four chamfered ribs.

Later in the afternoon the business of an ordinary meeting was transacted under the chairmanship of Mr. H. Goodall Quartermain. A large number of nominations were read, together with a list of donations to the Society's library, from the Royal Institute of British Architects, the Essex Archæological Society, and a number of architectural and archæological associations throughout the kingdom. Mr. E. A. Mann, of 66, Narford-road, Upper Clapton, was then elected a member of the society, and the business part of a highly-successful meeting was concluded.

After tea, some of the party inspected the Waltham Cross a short distance out of the town.

---

* I find, on further investigation, that distinct signs of arches do exist over the aisle windows in the western portion of the church, and over the great south door; it seems, therefore, necessary to admit that the aisles were vaulted.

A NEW VENTILATOR.

MESSRS. JAMES HILL AND CO., of 100a, Queen Victoria-street, E.C., are placing on the market a new patent in ventilators, which seems to embody one or two new principles. The ventilator is made in two distinct parts, which can be used combined or separately. The inner ventilator may be used for the extraction of foul air in the ordinary way into a flue formed in the thickness of the wall, or if it is desired to ventilate directly into the open air (which in many cases is an obvious advantage), the outer ventilator can be used conjointly with the inner ventilator; while again, if so desired, the outer ventilator may be used by itself.

The advantages claimed are as follows:—Inner ventilator: (1) A perfect flap ventilator under all atmospheric conditions; (2) a back-draught seals the outlet, the silk flaps fitting perfectly against the sloping sides; (3) ventilation always assured, for should the flaps not respond to a feeble outgoing current, a free passage is still secured (see the arrows on sketch). Outer ventilator: (1) Proof against rain and back-draught; (2) an upward current of air impinging on the baffle-plate will induce a suction; while (3) a downward current, even when accompanied by rain, will have free outlet.

The get-up of the ventilator is all that can be desired, and the design of the front is very effective, especially when made in brass. These ventilators have been used in the new Admiralty Buildings, Whitehall.

Our Illustrations.

TONBRIDGE SCHOOL CHAPEL, KENT.

THE geometrical drawings given herewith show the new buildings which it is proposed to erect at Tonbridge from the designs of Mr. James Brooks, this year's Royal Gold Medallist. That gentleman lent the originals to us for publication on the occasion of the presentation of the medal; but, owing to the tinting on the working drawings, some delay in reproducing them prevented the plates from being given earlier. The chapel is conceived in the style of architecture which marked the end of the 15th century, and its plan is designed after the fashion usually adopted in the Middle Ages for collegiate foundation chapels, the seats being arranged choir-wise. An important feature in the design is formed by the elaborate stone groining of the nave, the roof of which is to be covered with lead. Access to the roofs will be obtained by way of the stair-turrets situated at the east end of the building, and copper will be employed for their spirelets, which assume a Tudor outline in harmony with the fenestration. The chapel is 155ft. long by 36ft. wide, and on the south side the Founder's Chapel will serve for smaller congregations. The seating of the chapel proper will accommodate 450 scholars and 20 masters, with stalls at the west end for 12 superior masters, including the heads of the schools. The minor chapel is arranged for the use of visitors, as well as for early celebrations, and the families and domestics of the masters. The seating here contrived is reckoned at about 84 seats. An arcade of four bays connects the two chapels, and by these means a complete separation is secured for the boys and teachers from the other portion of the worshippers assembled for Divine service. A spacious vestry for the clergy and choir is situated at the west end of the Founder's Aisle. By the longitudinal section it will be seen how the organ is displayed over the cloister on the north side of the choir. The depth of this chamber is delineated on the cross-section, and the plan shows the circular stairway for the use of the organist. This cloister between the masters' house and the chapel furnishes its main approach from the schools. Its walls are arcaded, and fan-vaults form its ceiling. The western portal of the chapel opens into the boys' playground. The stone throughout, outside as well as inside, is to be brown Ancaster ashlar, and the estimated price, inclusive of stalls and furnishings, is stated by the architects, Messrs. James Brooks and Son, to be about £17,000. Ample elevation to the rear of the altar is provided for the erection of a lofty reredos, and it is to be noted that the floor of the sanctuary is only five steps above that of the nave, so that the full advantage of the area for seating has been obtained. In not a few school chapels the altar has been needlessly and inconveniently elevated for effect's sake, which is sometimes a questionable advantage.

CLUNY MUSEUM: MANTLE AND BALDAQUIN OF THE ORDER OF ST. ESPRIT.

A description of these will be found in "May Morris's" article on p. 71.

HOUSE AT WOODFORD.

This house has lately been built at Woodford. The walls are faced with red bricks, and the dressings are of Monk's Park stone. The roofs are covered with Eureka slates. The whole of the woodwork outside has been painted white. Messrs. Sumner and Co., Limited, of Hampstead, were the general contractors. The work was carried out from the designs and under the superintendence of the architect, Mr. R. A. Briggs, F.R.I.B.A.

THE EQUITABLE LIFE ASSURANCE SOCIETY; SYDNEY, N.S.W.

This building is described in our Australian contributor's article on "The American Romanesque in Australia," on p. 67.

"OUR HOMES."

Building Intelligence.

THE CAMPDEN TECHNICAL INSTITUTE.—On Tuesday afternoon, on a piece of ground adjoining the public library in Lancaster-road, North Kensington, the foundation-stone of a new technical institute in connection with the Campden Charities was laid by Princess Louise. As soon as the institute is completed the evening-classes in woodwork, wood-carving, drawing, dressmaking, and cookery now maintained by the trustees in North Kensington, and at present meeting in different places, will be moved into the new building. The building is to be two stories in height, and in red brick, with stone dressings. The whole of the ground floor is to be set apart for the boys, and the first floor for the girls. The architect (honorary) is Mr. Rowland Plumbe, of Fitzroy-square.

DARLINGTON.—The Bishop of Durham laid the foundation-stone of the new day and Sunday-schools in Greenbank-road, Darlington, last week. The buildings have been designed by Mr. G. G. Hoskins, F.R.I.B.A. The architecture is a simple type of the Queen Anne style. The materials to be used are grey clamp bricks, relieved with red pressed bricks and terracotta. On the ground floor accommodation is provided for 150 infants, and consists of a schoolroom 38ft. by 22ft.; a classroom 21ft. 6in. by 18ft. 9in.; a marching hall, 27ft. 3in. by 24ft. 6in.; teachers' room, a room for school cleaner and utensils, lavatories, hat lobbies, &c. On the first floor provision is made for 200 girls, consisting of a schoolroom 38ft. 8in. by 22ft., and two classrooms, each measuring 24ft. 9in. by 24ft. 6in. By an ingenious arrangement of quite a new description of movable partitions, one on the west side of the schoolroom and the other dividing the classrooms, two halls of different sizes can be formed, one about 50ft. by 24ft. 6in., and the other about 47ft. by an average width of 44ft.

LISCARD.—The foundation-stone of the new Christ Church (Reformed Episcopal), which is being erected on the site of the original iron building in Martin's-lane, Liscard, was laid on Saturday. The new building, which, when completed, will cost close upon £3,000, will seat about 500 adult persons. Space is being provided for vestries, organ chamber, &c. The tower, the lower story of which will be the entrance porch, will be disconnected from the church, and stand outside the second bay of the aisle, with ringing chamber and belfry above. The church is being built of brick, with Runcorn red stone dressings externally, and Storeton white stone internally. The architect is Mr. T. D. Barry, of Liverpool, and the contractors are Messrs. W. H. Bleakley and Co., of Birkenhead.

SHEFFIELD.—The new town hall at Sheffield begins to wear a finished appearance so far as the exterior is concerned. There is much bold, effective carving which no atmospherical conditions can obliterate. This is particularly noticeable at the main entrance, over which there is a large carving of the city arms, with its supporters, Vulcan and Thor. The figures, which are 11ft. high, stand out in bold relief. Mr. Mountford's design is the more appreciated the more of it is seen in execution, and Sheffield is to be congratulated on the possession of public buildings of such an artistic and convenient character. The Surrey-street block is very nearly ready for occupation. The city surveyor and his staff will take possession of their portion of it at the end of the present month. Work in the interior is being pushed forward as rapidly as possible. The ornamental ceiling of the council chamber is now exposed, the carving of the tracery windows completed, and the oak dado lining to the walls is being put into position. The marble staircase is being fixed in the hall, and the frieze to the Pinstone-street front, depicting the trades of Sheffield, will soon be finished.

STAFFORD.—The memorial stones of the new Baptist chapel in Lichfield-road were laid on Wednesday. The new church is being built from designs prepared by Mr. E. Harper, architect, Birmingham, and the work is being carried out by Mr. G. H. Marshall, of Smethwick. The buildings will be in the Tudor Gothic style, with bricks and stone dressings; but the spire will be of stone, with open tracery. The church is to accommodate 310 persons on the ground floor, while in a gallery over the main entrance room will be provided for 115 more. There will be a large church parlour, a deacon's and a minister's vestry. The schoolroom will accommodate 250 scholars on the ground floor. There will be six classrooms, four of which will be divided from the central hall by removable partitions.

COMPETITIONS.

EWELL SEWERAGE COMPETITION. — The engineers, Messrs. Taylor, Sons, and Santo Crimp, engaged by the district council to adjudicate upon the schemes sent in, have placed that of Mr. John Anstie first. The scheme recommended is that involving the removal of the suspended matters in the sewage, and the application of the effluent to land for final purification.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

NORTHERN ARCHITECTURAL ASSOCIATION.—The annual excursion takes place to-morrow, July 20. Members will assemble at the Central Station, Newcastle, at 11 a.m., and travel by the 11.10 a.m. train to Chollerford. On the arrival of the train, at 12.18, luncheon at the George Inn will follow, after which members will visit the new buildings at Chesters, carried out for Mr. Clayton. The remains of the Roman Station of Cilurnum in the Park, at Chesters, will also be visited, and will be explained by Mr. Robert Blair, F.S.A., who has very kindly consented to be present. The party will dine together at the George Inn, Chollerford, at 6.30 p.m.

CHIPS.

The Presbytery of Perth have agreed to restore the Middle Parish Church, Perth, to the state it was in before the recent fire.

A celebrated Russian art critic and senator, Dimitri Rovinski, died at Wildungen on the 23rd ult. He was well known by his publications relating to art history in Russia, but especially by his monumental work on the etchings of Rembrandt and his school. He was preparing a similar work on Ostade's etchings, and possessed one of the finest collections of engravings in Russia.

The rector and churchwardens of Market Harborough have received a report from Mr. W. Mitchell, stating that the upper portion of the fine spire should be taken down and rebuilt at once, as it has a considerable inclination towards the Market place, and the masonry is cracked.

At the last meeting of the Bangor city council, Mr. Webster, the engineer of the pier, reported that satisfactory progress was being made with its erection, and that the length of the portion erected, including the second embayment, was 635ft. A large portion of the timber joists, &c., had been laid to receive the deck sheathing, about 500ft. of the gunwale and fascia, and about 80 yards of the handrailing were fixed in position.

New board schools are in course of erection at Millbrook, Hants, at a cost of £10,000. Mr. A. F. Gutteridge, of Southampton, is the architect, Mr. A. F. Cawte, of the same town, the contractor, and the fittings are being supplied by Messrs. Illingworth, Ingham, and Co.

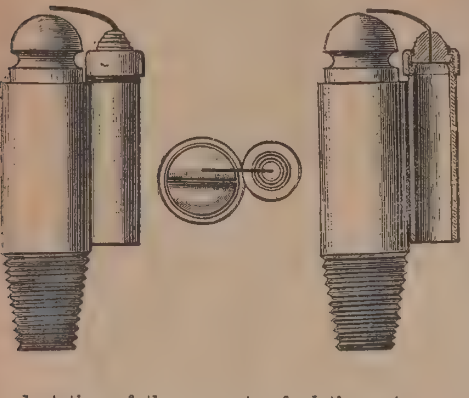
"OUR HOMES," by R. Barry Parker.—VIEW No. 2 OF HALL SHOWN ON GROUND PLAN.

DUKE'S SELF-LIGHTING GAS-BURNER.

WE illustrate below a new invention, which, on account of its practical utility, is bound to be a great success. It is a gas-burner which is absolutely self-lighting, and the advantages of such will be apparent at once when one takes into consideration the time and labour involved in lighting buildings where the gas-burners are out of ordinary reach. The principle is the adaptation of the property of platinum to cause the combination of oxygen and hydrogen, with development of heat, to ignite a stream of gas, and the method of application is explained by the illustration. To the body of a governor burner is attached a small tube, carrying at its top a plug of porous refractory material, in the pores of which platinum black has been deposited. Springing from this plug is a piece of fine platinum wire, which spans the distance to the burner with which it is parallel. All that is needed is to turn on the gas, which causes the porous plug to glow, and the draught of air through the small tube immediately helps to raise the platinum to a white heat, and thus lights the gas. It is claimed that the material used is practically indestructible and permanent.



COUNTY LUNATIC ASYLUMS.—XXII.

By GEORGE H. BIBBY, F.R.I.B.A.

ASYLUM LAUNDRIES.

IN connection with large asylums where an isolated hospital for fever and smallpox patients exists, a special laundry of small extent should be provided in proximity therewith. This may consist of three or four apartments, including a disinfecting-room or closet, a reception-room, washhouse, laundry, and drying-closets, &c. Should the fever hospital be fenced from the asylum grounds with walls or railings, &c., the laundry and drying-ground might also be inclosed, as it is obviously necessary to adopt all reasonable precautions against the intrusion of insane patients, careless attendants and nurses, workpeople and visitors within an infected area.

Unless the medical officers should consider it sufficient that all linen and cotton articles from the fever-wards should be steeped for an hour or so in a mixture of disinfecting emulsion with water, with subsequent boiling, or other similar treatment, it would be necessary that the architect should include in his plan a small disinfecting closet, operated by hot air and steam, the larger goods, bedding, &c., being taken, perhaps, to the disinfector attached to the general laundry, or being burnt in a destructor when advisable.

There should for all laundries always be a sufficient supply of absolutely pure soft water. In some districts the water, though soft, may be strongly impregnated with organic matters, or it may be hard by reason of its having come in contact with or passed through mineral strata. By filtering either of the above described waters these objectionable qualities can be taken from them, leaving the liquid apparently perfectly clear. Should it still remain hard, caustic soda is sometimes added in the proportion of 2oz. to each 100 gallons of water. The cisterns in which these mixtures are made should have an outlet at the bottom for the escape of the mud, &c., when necessary, and the pipe for drawing off the water should be at a height of 3in. or 4in. from the bottom that the opening may not be obstructed by the sediment. The question as to whether or not these cisterns would be required, and their size, is one that may influence the planning of the laundries, and should be considered by the architect at the outset.

In some instances the asylum committees, or county councils, prefer to take the opinion of their architects or engineers (rather than that of their medical officers or other officials) as to suitability of fittings and appliances, for laundry and other purposes; but this knowledge on the architect's part can only be the result of considerable inquiry and consideration. For instance, take the apparently simple question as to the provision of a system of drying-closets and drying-grounds. Upon this subject an American writer says: "Great care should be taken to preserve an even temperature during the whole operation of washing and drying. A draught of cool air from an open window or door will often cause the flannels to shrink. The open air on a summer's day is the best drying-ground, but the articles *should be put in the shade*, as the sun's temperature often exceeds 100°." Again, another writer claims to have "perfected a new steam-heater for laundry drying-rooms, the design being intended to insure rapid evaporation of moisture without the possibility of *discolouring, which so often follows the use of over-heated dry air.*"

In planning asylum laundries it will be observed that the alternatives of hand-washing and machine-washing may influence the architect considerably in deciding upon the lengths, widths, and areas of the laundry apartments; and, further, some machines are much less economical than others as regards the space they would occupy. Machines are made which almost form washhouses in themselves, and there can be no doubt that laundry machinery would be made much more use of in asylums were it not desirable to find employment at the washing-troughs for the female patients.

There is a very compact machine which should reduce the floor-space of a laundry very considerably. It consists of a circular and comparatively shallow metal tank mounted on trunnions; inside the tank there is a perforated metal cage, divided into three compartments for the reception of clothes. The outer casing has one large door, and each compartment of the cage has a separate door. This cage is carried on a spindle running through its centre, fitted with special ball-bearings, cone, and other gearing, for enabling the transformation of one machine into another to be effected with rapidity and ease. Owing to the shape of the machine, comparatively little water is needed, and as the compartments are triangular, the linen in each one is raised and dropped three times in every revolution, and falling into the angles, is squeezed and rubbed against the sides, thus insuring thorough, but not too violent, rubbing. When the washing process is completed, the dirty water is run out; then the operator takes hold of a lever in front of a spur cogwheel, and slips a sliding clutch out of gear. This automatically throws the reversing apparatus out of gear. Taking hold of a hand-wheel, he gives a turn or two, and the whole washer (outer casing and inner cage) swings round horizontally. A friction cone, fixed to the end of the central spindle at the bottom of the outer casing, comes into contact with a vertical cone fixed to the under shafting. The apparatus is locked in that position, and the cage inside the outer casing whirls round at a high speed, being converted into a hydro-extractor or a centrifugal wringer. At once the dirty water is forced out of the linen by the rapid motion, and escapes through a waste-pipe. When all the dirty water is extracted, the machine is reconverted into a washer; hot water is run in, steam is admitted, and the water raised to the boiling point while the machine revolves—first from left to right, then from right to left. Once more the machine is converted into a hydro-extractor, and the fluid removed; back again it is converted into a washer, for rinsing purposes and bluing. Then there is the final "hydroing," and the linen is removed, white and dry, to the ironing room. It will be seen that there are many excellent points in this system, apart from its economic value. To begin with, there is the minimum handling of linen (apart from the frequent necessity for providing labour for female patients before referred to), there is disinfection by boiling and the admission of steam under pressure, and, above all, the dirty washing water is thoroughly removed before boiling commences, and the boiling fluid is extracted to the last drop before the linen is rinsed." We have here all the absolute requirements far a very thorough cleansing and disinfection, and upon a moderate amount of floor space, and for those asylums where laundry machinery may be advisable rather than hand-labour, the desirability of making use of such appliances as the above may well be considered by the asylum architect, and with the view of limiting the cost of the laundries by reducing the areas and cubical contents of the building as far as possible. These are frequently of great extent, and form one of the most costly departments of an asylum, the machinery and appliances being items that should always be of high-class manufacture, and supplied by firms who have had special experience in asylum requirements.

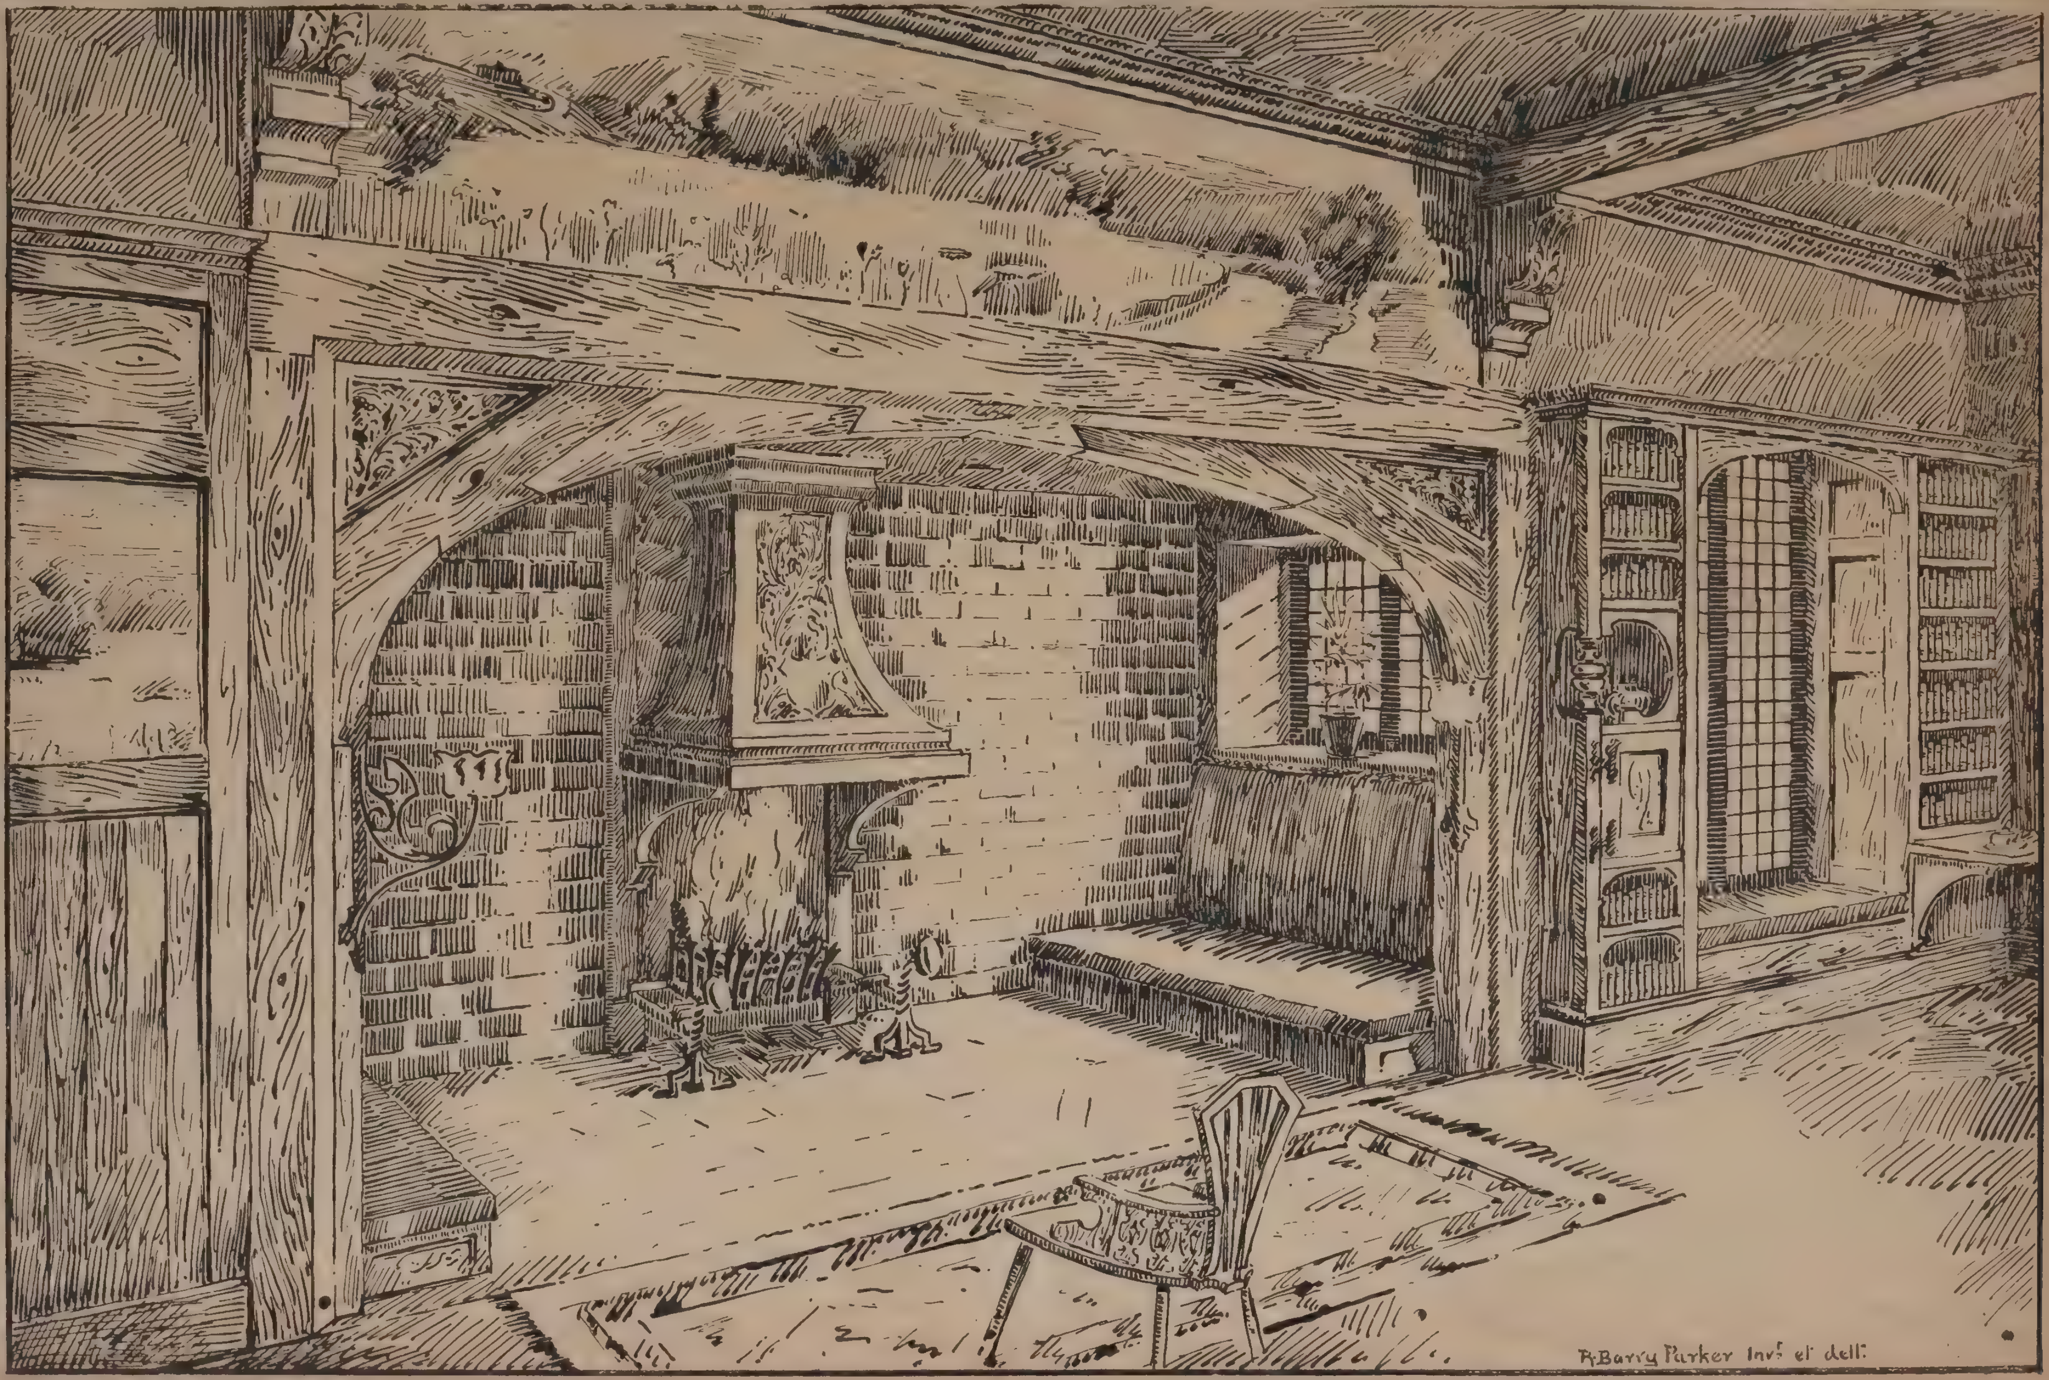
In connection with a laundry, and as a means of occasional or even permanent employment of both male and female patients, a small dye-house might be arranged for. I believe that such accommodation has been provided in American and other foreign asylums, and it is not improbable that some asylum committees may be advised by their medical superintendent that such work as dyeing may be added with advantage to the institution, and possibly with some profit. In some districts there is a difficulty in finding suitable employment for the insance patients, and suggestions upon the subject would be of utility.

In a former paper I directed the attention of the readers of the BUILDING NEWS to the asylum at Gheel, in Belgium, where the patients, instead of being confined in one building, are lodged with the population, each inhabitant taking one or two inmates. These live with, and are employed by, the residents, working with them in the fields, domestic duties, or trades, &c., and it would appear that many skilled occupations may be adopted for the utilisation of the labour of the insane. Since the publication of the above in the BUILDING NEWS there has been published in the *Cornhill Magazine*, for June of this year, a very interesting account of the asylum arrangements at Gheel under the title "A Colony of Lunatics." The institution appears to be very ancient, and the insane have a greater freedom there than would appear to be at all practicable elsewhere. Should, however, a patient present himself at the railway station, he would find a difficulty in obtaining a ticket or seat in the train, the whole population being on the watch at every point. The patients obtain pay for their work, and go to and fro amongst the population without restraint (except when necessary for their protection); for instance, a patient may enter an inn and would be served with one glass of drink, but should he ask for a second would be politely refused. The ininhabitants—men, women, and children—are more or less engaged upon the care of the insane, who appear to be treated with kindness, courtesy, and the utmost care.

The asylums of the world are peopled (in the minds of the inmates) with creatnres of the imagination and of all descriptions, pleasant, ridiculous, and disagreeable, yet such hallucinations have attacked many celebrated men, who though subject to them could not properly be classed as insane, and the causes for certain persons fancying that they can hear, see, and perceive where others cannot, are subjects for scientific examination teeming with interest. A recent article in an American journal suggested that there are yet well-educated people who believe in the supernatural, and that this belief does not proportionately decrease with the growth of logic, science, and enlightenment. The pleasures of the imagination are as enchanting as its terrors are distressing; aud when people plunge into an unreal world of their own creation, the forms of hallucination upon the minds of the sane, as well as of the insane, are infinite, wherever and however these take their birth. Solitude is often the great foster-mother of these troubles. To combat such unsound impressions, to console, amuse, and interest the patients are duties which every official in an asylum should perform. In many cases these duties must necessarily be painful; but from the example given at Gheel it would appear that large numbers of patients can be sufficiently attended to even by the youngest members of the families intrusted with their care; and as regards the cost of maintenance and lodging, the materials for a comparison might be found of considerable utility.

(*To be continued.*)

A new mission church, to be called St. Peter's, intended to be a chapel-of-ease in connection with St. Anne's, Southowram, was opened at Brookfoot, near Brighouse, on Saturday afternoon.



R.Barry Parker Invt et delt.

"OUR HOMES," BY R. BARRY PARKER.—A LIVING ROOM.

OUR HOMES.

By R. Barry Parker, Architect.

"IF a man can cut such a head on his stone gate-post as shall draw and keep a crowd about it all day, by its grace, good nature, and inscrutable meaning; if a man can build a plain cottage with such symmetry as to make all the fine palaces look cheap and vulgar; can take such advantage of nature that all her powers serve him, causing the sun and moon to seem only the decorations of his estate, this is still the legitimate dominion of beauty."—Emerson.

Build a plain cottage that such make all the fine palaces look cheap and vulgar! Generally the cottage such as Emerson is imagining is unnecessary to this end; our fine palaces look cheap and vulgar enough, though we have no such cottages with which to contrast them.

But setting aside the palaces for the moment, could we not build cottages that would make the home of the average Briton look cheap and vulgar? The cottages are less necessary in this case than they are in the other; dozens of country cottages do it now, and the average farmhouse kitchen does it most effectually.

That the farmhouse kitchen has an artistic value far beyond that of the average drawing-room, any one of real artistic feeling will at once admit; and why? In the first place, there is an element of truth and honesty about it, very different from the artificiality, falsity, pretension, and sham of the modern drawing-room. But, apart from this, there are many faults which the drawing-rooms have in common with most other rooms in the house of the average Briton.

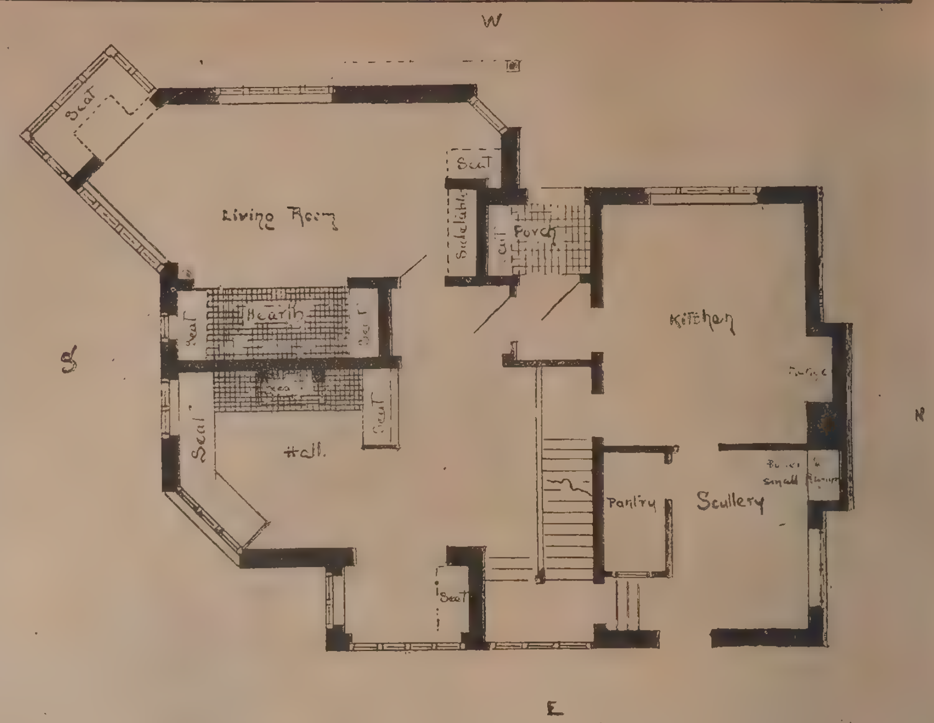
One of these faults (which might also be said to be universal) is over-decoration. Everything has a pattern in it; almost every pattern is mechanically produced, run out by the yard and cut off just where it happens to be when the time comes for it to stop; no pattern bears any relation to any other pattern in the room, and the whole effect is painful to a degree. Nothing is let alone, but every surface must needs be worried and tortured into some unwholesome form of mechanically-produced, and altogether soulless, ornament. Tortuous intricacies of design meet our eyes wherever they turn. Ceiling, walls, floor, curtains, cushions, fireplace, everywhere and everything is one mass of ornament (so-called), and yet often there is not a square inch of *real* ornament in the whole room.

How much of this ornament was done because it gave any pleasure *in the doing?* It is manufactured ornament. What a contradiction in terms! It is one of the *processes* each thing in the room has gone through in its maufacture, so it has been done as cheaply, and therefore as mechanically, as possible. Often it is done because it is cheaper than workmanship in making a thing look a lot for the money, and often because it helps to disguise bad workmanship. At any rate, it is not done in that true spirit of ornament, the desire of the workman to make his work beautiful for the love of it.

How much of this ornament is there because it gives any pleasure to those who use the room? It is there (like so many other things in the room) not because they get any pleasure from it, but because they think it is what is required of them by the class of society to which they belong, or, more often, to which they would wish to be thought to belong; it is the fashion—custom, other people have it. And observe, all this ornament is made to shout: everything is clamouring for notice, trying to assert itself, to attract attention.

Now the first essential in the form and design of any decorative object (and everything in a room should be a decorative object) is reposefulness. This everyone knows, and it sounds somewhat like a platitude; but this first principle is almost universally violated, and in every possible way, one way being this assertiveness. Any ornament you notice when you do not look for it—or perhaps it would be better to say when you do not wish to think of it—is necessarily in bad taste.

A room is so seldom designed *as a whole;* never enough thought of as a whole. The designer of each individual thing, knowing nothing of the form and character anything else in the room was going to take, thought only of his own design, and worked enough interest and incident into it to make it all-sufficient in itself, and the result is (when it gets put into a room in conjunction with a lot of other things designed in just the same spirit), it adds to that restlessness, fussiness, and fretfulness.



"OUR HOMES," by R. Barry Parker.—GROUND PLAN OF HOUSE.
(Designed for Alfred Buckle, Esq., of Derby.)

But so long as the present method of preparing a house for habitation holds its own, no really satisfactory result can be arrived at. So long as one man designs the house, another arranges the decorations, and a third picks up the furniture of twenty designers, and all the hundred and one other things which go to make up the complete room, here, there, and everywhere, our homes will be the painful places they now are. It is essential to any good result that one man should design the house as a whole, not necessarily that he should design everything in it, or draw with his own hand every detail; but he must exercise a controlling power, selecting where he does not design, and insuring that the work of all may be done in a spirit of co-operation towards a complete whole which he planned. Until houses are planned in this way, such rooms will continue to result as those to which we have, unfortunately, most of us, become too much accustomed, and are, some of us, quite content with.

Say a man is asked to design, for a firm of furnishers, an overmantel to cost 30s. It has to be one that will go anywhere. Now this designer may feel that in many of the rooms into which his overmantel will be introduced, nothing nicer could be got for the money than a simple frame with three panels in it; but he cannot send this in as his design, so he has to set to work and design an overmantel with the aid of vulgar stock machine-struck mouldings, run out by the thousand yards, spindly, shapeless, and senseless little balustrades and turnings, also so designed that they can be turned off by the thousand, and it must be run together with the jerriest joints and smeared over with stain and French polish to hide the machine finish and bad workmanship, or it will not come out at the price. If he were designing the room as a whole, and were looking upon the overmantel, as he should, as only a part of the whole, he could put up his frame and three panels if he liked.

Our larger houses have generally, on the ground floor, drawing-room, dining-room, library, kitchen, and offices, and perhaps music or billiard-room; all tolerably good rooms. Now, when a smaller house is wanted what is done is to take a plan suitable for this larger house, and reduce it in every way, instead of designing a house suited to the new requirements. We put exactly the same number of rooms as we had in the larger house, only reducing all in size, until the house comes to be divided up into places so small we can only call third-class compartments, all far too small to give room for the comfortable pursuance of any of the ordinary natural occupations of life, and too small to be healthy.

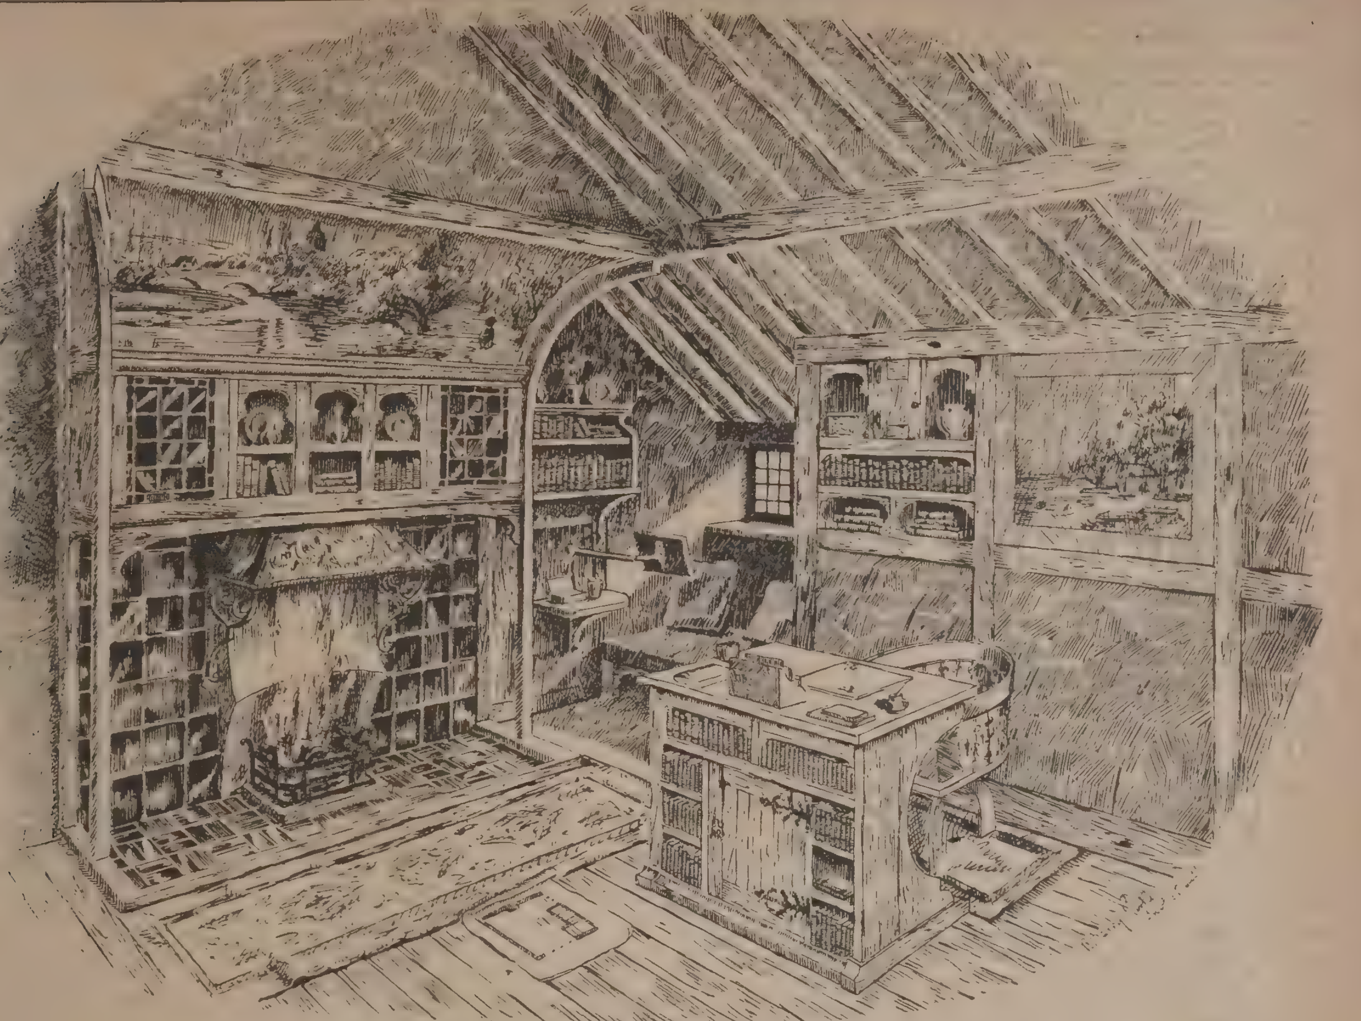
And this system is what is adopted in all classes of houses, from the suburban villa down to the smallest cottage. We never do away with a room until we are *driven* to it; we build four ground-floor rooms until we reach the point at which they would all be *absolutely* useless; then we build three until the same point is reached; then two, and so on. In the smallest cottage it is just the same—a little back kitchen where the family lives, and a little front room no one ever goes into, except to clean; until we get to a dwelling so small that the one little back kitchen is the only room.

Where do we ever find a cottage with one big living-room? Or a dwelling such as would suit the real requirements of many, belonging to almost all classes of society—a dwelling containing one good living-room, a sanctum, and a scullery? Or even a house with two good rooms, kitchens, and offices? And for what do we all cramp ourselves in this way? Generally, only that we may have one or more of these compartments, which are practically no good to anyone. There are very few houses, from the cottage upwards, in which there is not a room which is virtually never used, or only used for the sake of it.

The same idea is religiously carried out in the decorations and furniture. Instead of these being designed to suit the conditions and circumstances in which they are to be placed, each designed for its position and purpose, and good and honest as far as it goes, though perfectly simple, if necessary, we find cheapened imitations of the sort of thing found in larger houses, cheapened by being badly made, by cast or otherwise mechanically produced ornament instead of wrought; by veneer on pine instead of solid wood, by cast metals made to look like wrought, by machine-carved wood, by marbled slate, &c., &c. And they are as unsuited to their new conditions in design as they are lifeless in conception, and bad in workmanship. For one thing, the things in the larger house of which they are imitations, were often designed under the mistaken idea of filling up a room as much as possible—making it look furnished, we call it. Whether this was wanted in the larger house or not, it is certainly not wanted here.

The hall in the house of the average Briton should be made a great deal more of than it ever is. It might be the most comfortable room in the house, and the centre of the common life of the household; but it is generally one of two things—it is either a passsge with a kind of step-ladder for a staircase, and a hat-stand in it, and not room enough for you to hold the door to let a friend out; or it is a great, cold, bare, comfortless waste space in the centre of the house.

Of course, a house with a hall of this kind needs some care in planning. In the first place, the staircase must occupy exactly that position in which it can be made an ornament and a pleasing feature in the room (all of which it is quite capable of being), and a position in which



"OUR HOMES," by R. Barry Parker.—A STUDY IN THE ROOF.

it does not detract from the cosiness, or give any unpleasant feeling of draughtiness or too great openness.

In the second place, the doors necessarily opening into a hall must be carefully so grouped that the parts of the room in which anyone would sit should be out of the draught of them.

By converting the hall into such a room we utilise to the full the air space in the house, and the hall fire, for in most houses it is found necessary to keep a fire of some kind burning in the hall through the winter, or the whole house is cold, and most people find it necessary to keep two other fires burning, one reason being that there may be somewhere to show visitors. Now, when the hall is a sitting-room, we get for the trouble and expense of two fires all the advantages ordinarily attaching to three.

(*To be continued.*)

NOTES FROM PARIS.

ALTHOUGH the complete scheme for the Exposition of 1900 has been prepared since some little time, nothing has as yet been decided upon regarding the commencement of the work, for certain difficulties have arisen between the Exposition Committee, the Paris Town Council, and the State, regarding the share which each should take in providing the necessary funds for the work. Several members of the Chambre have desired that the question be left open until the next Parliamentary session. It is, therefore, probable that nothing, or very little, will be done before the beginning of next year. The estimated cost of the exposition is four millions sterling, of which sum it is proposed that the town of Paris should provide £800,000, the State a like sum, the remaining two and a half millions to be provided by a financial syndicate who would guarantee the finding of that sum. It is proposed that the town of Paris should pay its share by means of five annuities from 1896 to 1900; but before voting this credit, the members of the council desire to assure themselves of the bona fides of the financial syndicate, its formation, and of whom it will be composed. Two important questions are also brought up—that concerning the octroi or entry duties on all materials employed in the construction of the exposition, and that concerning the compensation allowed by the State to the town of Paris for the buildings now existing on the Champ de Mars, the Trocadero Gardens, and the Champs Elysees. As regards the octroi duties on the materials of construction entering Paris, it was proposed that all moneys received from the tax should help to make up the share of funds to be provided by Paris; but after a lengthy discussion it was agreed that this tax could not be allowed, the palaces and buildings of such an exposition being classed as exhibits. The entry of all goods destined as exhibits is free from duty under the condition that as soon as the exhibition is over such goods and materials be at once taken out of Paris. In the case, however, that any of the buildings remained or were bought by the town after the Exposition, the tax which should have been paid on the materials on their entry into Paris would then become recoverable. As regards the second question of compensation for the existing buildings to be demolished, and now owned by the Town of Paris, it has been agreed that after the exposition is over, new buildings covering the same surface of ground as at present on the Champ de Mars, Trocadero, and Champs Elysées should be handed over to the town; again, Paris will have the right to take over all materials coming from temporary building which the State is obliged to pull down at the end of the Exposition. It is also agreed that the promenades, avenue, and gardens shall be restored to the town in the same state as now existing, and during the whole course of the work the State will provide free traffic circulation in the Cours la Reine and the Champs Elysées. All the above questions have been satisfactorily decided between the Town of Paris and the State, the all-important matter, which will require some little time to arrange, concerns the share of expenses to be borne by each party.

The question of the metropolitan and the passenger railway traffic for the coming Exposition is indeed most unfortunate. The committee of railways at the chamber has just thrown out the two schemes submitted for the junction of the Champ de Mars and the Esplanade des Invalides with the Cluny-square and the Orleans station by way of the Boulevard St. Germain, and again the Champs de Mars with the Gare St. Lazare by way of Passy. The first scheme, however, receives approbation, the second scheme being considered as offering a too-circuitous route and being too complicated, necessitating a series of tunnels and a viaduct across the Seine. The whole matter will be again studied and brought up in another form.

It is seriously questioned to utilise the force of the River Seine for lighting the Exposition by electricity, and distributing motive power for various uses in the grounds. One of the twenty-two dams of the river. That nearest the Champ de Mars at Suresnes is considered the most suitable for the purpose, where the power of a little over 2,000c.ft. per second falling 10ft. is available at low water. It is estimated that the power thus obtainable at the Exposition itself would be about 1,300H.P. (French = $1\frac{1}{2}$cwt., 39in. high in one second). In order to make the undertaking profitable, the installation would remain after the Exposition, and the motive power be distributed for various uses in the neighbourhood.

It is proposed to pull down the fine observatory at Montrouge, Paris, and reconstruct a similar building outside the fortifications at Meudon, the large space of ground occupied by the existing building being wanted for the prolongation of the Boulevard St. Michel.

The inauguration of the aqueduct of Acheres, the first important step towards the sanitary drainage of Paris and the system of the Tout-à-l'Egout, took place last week. The system will be one of complete centralisation. Up to the present the two important collectors or main drains, one on each side of the Seine, collecting the drainage from the two portions of Paris, had their outlet into the Seine at Asnieres. By the new arrangement these main drains are now led as far as the converting works at Herblay, where all drainage is made to pass through reservoirs containing a system of gratings holding back all solid matter, which is finely triturated by means of powerful toothed wheels worked by steam power, and carried off at intervals by means of a strong head of water to the fields, where the matter is employed for fertilising purposes. The liquid portion, after a preliminary purification at the Clichy works, and a further similar operation at the Herblay converting works, will be run off over 2,000 acres of land extending to the north of the Forest of St. Germain. The important portion of the work of construction of the aqueduct carrying the drainage across the Seine from Clichy to Acheres is now completed, at a cost of about £400,000, including the preparation of the land for spreading purposes. In order to insure a complete security, and diminish the expenses of maintenance, the use of closed culverts has been restricted as much as possible, and limited to the near neighbourhood of villages and other places where such work was a necessity. It is considered also that the carrying of drainage by means of open aqueducts is very advantageous. The matter, owing to its constant contact with the open air, is prevented from developing microbes and fermentation, arriving thus at the converting works in its almost primitive state. Comparison is made between this system and that of the forced aqueducts of Berlin, where the decomposition of drainage matter is most obnoxious.

Much controversy has been occasioned over the question of the obnoxious smells which each evening during the summer-time spread over large portions of Paris, making the evening stroll or idle hour at a *café terrasse* quite an unpleasant occupation. It is not yet decided whether these bad odours are due to the drains or to the numerous alcohol works lately started to the east of the city, or from other sources; but in order that the cause should be determined as soon as possible, a committee nominated by the police and the town council has been appointed, with mission to discover the causes, the means of remedy for the unpleasantness, and the reorganisation of the service of authorised manufactories at Paris.

The important question of the prolongation of the fine Boulevard Haussmann is again coming up, but rather too late, for an immense "immeuble" or flat dwelling of seven stories has now been constructed across the line of prolongation, and is fast nearing completion. The expropriation of the old buildings which occupied the place of the present new construction, together with the surrounding valuable ground, was estimated a year ago to cost about two million sterling; at the present time must be added the purchase of the fine new building and compensation to the tenants.

The Society of Architects of Seine Inferieure is busying itself on the question of the restoration of the very interesting Chapelle du Lycée Corneille at Rouen. This is one of the largest of the parishes churches in France, measuring 165ft. by 145ft. The first stone was laid in 1614 by Marie de Medicis. The architecture of the building is very remarkable, forming the very rare example of the Transition from that of the Middle Ages to the Later style. As it is proposed to demolish this church, and erect a smaller one in its place, the Society of Architects is taking the matter in hand, and urgently asks for the funds necessary for a proper restoration of the building and consolidation of the portions which may need strengthening.

The *Bâtiment*, a Paris building publication, opens a competition amongst architects for designs of a "bicycle stable" in a flat dwelling-house. The bicycle is now so much *à la mode* at Paris that architects find the necessity of including in the plans of a number of new buildings proper and well-studied arrangements for putting-up and "stabling" bicycles; a certain number are making quite a speciality of this planning.

The drawings, restorations, and studies sent in by the Prix de Rome students at Rome are now being exhibited at the Ecole des Beaux-Arts. M. Sortais sends drawing of the actual state, and a study for the restoration of the Canope of the Villa Adriana. M. Tournaire sends measured work, the ensemble and the details of the Temple of Apollo and its treasures at Delphes, with indications of the state of the excavations at recent dates. M. Eustache presents a well-executed drawing of the ceiling of the Senate Hall at Venice, a half-dozen water colours of interesting portions of Pompeii, several views of the interior of St. Mark of Venice, and measured details of the ancient columns of the Temple of Castor and Pollux at Rome. M. Bertone sends a very brilliant series of sketches at Rome, and measured details of portions of the Forum at Pompeii, the Temple of Mars at Rome, and fragments from Pompeii. M. Chaussemiche sends, as his studies of the first year, several very cleverly-rendered details of temples at Rome.

A congress of economical dwellings will be held at Bordeaux from the 20th October next, before the closing of the exhibition now being held in that town. The programme promises to be very interesting, and papers will be read on the latest improvements which have been made in respect of such dwellings in all countries.

The Parisian public, and even the architects, do not at all seem to be convinced of the success of the new scheme of drainage for Paris. The professional and public papers are constantly publishing articles condemning the system of entire flushing drainage, a number preferring the existing system, and others proposing a compromise between that and the proposed system, several architects and engineers bringing forward various more or less ingenious and practical apparatus guaranteed to obviate all the inconveniences of flushing tanks, down-pipes, and siphons. An article by a well-known and experienced English architect or sanitary engineer would certainly be found very interesting, as coming from a country where every practical experience has been made of the proposed system.

The inauguration of the monument at Courbevoie, near Paris, erected to the "Victims of Duty" has taken place. The work is from the designs of M. Leroux, architect, and M. Segoffin. sculptor. The monument consists of a quadrangular pyramid of pink Scotch granite, about 10ft. high, mounted on a massive granite base, with sculptured flowers and bronze wreaths and palms. The magnificent funeral monument from the chisel of the celebrated sculptor, Bartholomé, and much admired at the Salon of the Champ de Mars this year, will be erected in the Pere Lachaise cemetery, at the end of the principal avenue. This monument will be placed over the burial vaults to be constructed by the town of Paris, and destined for the funerals of celebrated persons. The purchase and installation of the monument will cost £6,000, of which sum £4,000 will be paid by the State, and the remainder by the Paris Town Council.

The public exhibition of the work of the competitors for the Grand Prix de Rome for painting will be held at the Ecole des Beaux Arts next week. The subject of the competition is the body of the dead Christ bewailed over by the Holy women at the foot of the Cross.

The new hall of African antiquities at the Louvre Museum was inaugurated by the President of the Republic this week. It contains several interesting examples of mosaic work, including the celebrated Constantine mosaic, also several statues, or fragments of statues, showing strong evidence of the influence of the Ancient Greek and Latin schools; only a small portion of the interesting antiquities found in the North of Africa have been installed up to the present, the remainder, which it appears is still more interesting, will be brought to the Louvre as soon as possible.

The Senate is at present discussing the new law concerning "professional risk and responsibility for accident." The first few articles which have been voted may not be uninteresting for comparison with the similar law existing in England, and applicable to architects, engineers, and builders. The following indemnities are now due by law to workmen or others injured or killed during work; for partial incapacity from work, the compensation to be allowed is equal to half of the wages which the workman would have earned during the time the injuries prevent working. For an absolute temporary incapacity through injuring, the compensation due is equal to half of the daily wages during the time of incapacity, the indemnity not exceeding, however, 3s. per day. For an absolute and permanent incapacity through injury, the compensation is a yearly allowance equal to two-thirds of the annual wages of the injured person, who has also the right to claim as an immediate payment a quarter of the sum necessary to form the capital which would produce the yearly indemnity, the capital being calculated according to the mortality tables; he can also exact that this yearly indemnity due to him become payable at his death to his wife, in the proportion of the half of the indemnity. When death is occasioned through accident, the widow of the victim can claim an annual indemnity equal to 20 per cent. of the annual wages of her husband, on condition that the marriage was made before the date of the accident. If the widow re-marries, the indemnity ceases at the end of three years after the date of the new marriage. An annual indemnity equal to 15 per cent., 25 per cent., 35 per cent., and 40 per cent. of the average annual wages of the victim is due to his orphans if these are one, two, three or four respectively, up to the age of 16 years. Natural children of the victim, recognised before the accident, have equal rights with the legitimate heirs. If the victim had neither wife nor children, the father or mother of the same, or other ascendants having rights, can claim an indemnity equal to 20 per cent. of the average annual wages. The burial fees of the victim are payable by the person responsible for the accident, up to the sum of £4. The indemnities are payable in advance, and quarterly or fortnightly, in the case of partial or temporary incapacity.

The International Health Exhibition, opened in Paris on the 27th last, at the Palais des Arts Liberaux, has up to the present enjoyed a decided success. The exhibits are divided into ten subdivisions—sanitation of private and public buildings, town sanitation, hospital sanitation, health statistics, sanitary science, school sanitation (children's schools, hospitals, crèches, &c.); industrial and professional sanitation, food, clothing, and physical exercises. There are a large number of very interesting exhibits, both as regards the practical portion of sanitary work and as regards the adjuncts of all kinds necessary to clothe this work, and to afford every kind of convenience in public and private buildings. There are a large number of more or less ingenious apparatus supposed to do away with the inconveniences of the flushing system of drainage, also a quantity of various systems of flushing tanks and siphon reservoirs. Decorated ware of all kinds and styles is the rage. Ceramic and other tiles for the lining of the walls of w.c.'s, lavatories, and bath-rooms give the exhibition a very bright appearance, and some of the model installations of such rooms are exceedingly tasty, but probably rather expensive if executed. A new material for the lining of walls of w.c.'s, bath-rooms, &c., employed also for lavatory table tops, urinals, and other sanitary work, manufactured by the Glass Co., of St. Gobain, and entitled "Opaline," probably owing to its opal colour and surface, attracts much attention, especially from architects who profess to follow after the principles of their master, M. de Baudot, originator of the now fast-growing rational method of design and construction.

The town of Paris has arranged a most interesting and complete exhibition of drawings and working models of the appliances employed at Paris for town cleaning and sanitation, a set of models of the various systems of drains constructed at Paris, with working models of the most important drain-flushing reservoirs, the various systems of street-paving, and the materials employed. One of the "clous" of the Exposition is a monumental fountain placed in the centre of the grounds, and connected with the four water services by which Paris is supplied. The sample of Seine water is decidedly unpleasant-looking, and the unfortunate Parisians will turn with even greater disgust from the slimy-looking beverage which, even now in summer-time, they are occasionally asked to drink. But on the other hand, the numerous systems of filters, which profess to make the water perfectly pure and healthy, may be seen at the exhibition, and the sale is considerable.

We will give an article on the principal and most interesting exhibits and improvements in sanitary appliances, and a *résumé* of the Congress of Sanitary Architects and Engineers, with the interesting reports read by the chief members.

ARTHUR VYE PARMINTER.

At a meeting of the Exminster restoration committee, it was unanimously decided to remove the west gallery and to open the lower, in addition to the scheme already decided upon. Messrs. Andrews, of Teignmouth, having withdrawn their tender, the work has been intrusted to Mr. Herbert Read, of St. Sidwell's Art Works, Exeter.

The Bournemouth town council adopted, at their last meeting, plans prepared by the borough surveyor, Mr. F. W. Lacey, M.S.A., for a fire-brigade station at the East-yard, and also instructed Mr. Lacey to prepare the plans for the chapels and other buildings at the cemetery. For the latter work the surveyor will be paid an honorarium of 120 guineas, out of which he is to pay for any outside assistance required in the preparation of the designs.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING FOR TWENTY-FOUR WORDS, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—E. S. Fraser.—W. M. and Co.—Civ. Eng.—B. J. E. (Carlisle).—F. J. S and Co.—W. O.

Correspondence.

THE ARCHITECTURAL PROFESSION IN THE NORTH OF ENGLAND.

To the Editor of the BUILDING NEWS.

SIR,—A peep behind the scenes is sometimes interesting, especially where professional life is concerned. I came across a man a few days ago who is, it appears, to have a lot of work, and as I knew him intimately I could elicit a few facts.

Said I: "Why, your father was only a pitman, and you had no proper professional training."

"I'll let you into a secret," says he. "Treat architecture as a business, and get your material on appro."

I did not quite follow him, so he explained.

"For instance, a large competition comes out, and plenty of time for preparing the drawings. I guarantee that by advertising in the BUILDING NEWS, without giving a name, I can get assistants from some of the best offices in the kingdom. Well, when they come I make a great fuss of them; they let me have notes and copies of drawings they have taken from their employers' offices. When I have got all I want out of them, I pretend to have decided to throw up the competition, and ask them to take less than I agreed to give."

"And do they take it?"

"Well, the real gentleman who has money does, when I plead poverty; but the cad doesn't, I have to square him to keep him quiet. In one competition I have had suggestions that have emanated from our leading men by simply changing my assistants as often as possible."

"Do you ever win a competition that way?"

"I have won several by this means; but I get rid of *the* assistant before the award is made. Anybody does to fill the office up afterwards. Now, for instance, I have a boy who knows nothing, so I pay him nothing. I have an old foreman out of a furniture shop, who doesn't know whether a relieving arch is something in iron or wood; he has money, so I pay him what I like. The other fellow was a chemist, whom I told that if he worked for me for a trifle he could get into a good office afterwards, and ask for a good salary."

It certainly seemed a profitable and businesslike way of using a profession. In another instance, upon inquiring who prepared the drawings for a certain building, I was told a lad 16 years of age, who was in —— office.

"I only paid him 10s., and if his employer had been engaged he would have wanted about £20," said the man.

I see by a North-country paper of last week that a young man, calling himself an architect, was sentenced to three months' imprisonment for obtaining 2s. 6d. under false pretences.

I was almost moved to tears when I heard the story of one old man, an architect who at one time had fine offices and a large staff, and a man, they say, who was ever ready to put his hand in his pocket to help a starving professional or an assistant, and during the pitmen's strike many a family knew where a meal could be obtained. His wife, much younger than himself, but a lady in every respect, was keeping herself, young children, and invalid husband by teaching languages and music. It appears the old man, broken down in health and spirits, had not in one year made £5, and even that money he had made principally by teaching French and deportment, &c.

I was shown a set of architect's quantities: a contractor was wondering how he should price them out. Nearly every other item had but a vague description, and no dimensions against it, with the word "say" at the end; but the architect had in each case forgotten to say what the guess amount was to be. In one town I know of about 20 men who practise the *profession* of architect, auctioneer, builder, and undertaker.

I cannot help feeling for the genuine, honourable, professional gentleman who has to fight against such a crowd. AN OLD SUBSCRIBER.

Intercommunication.

QUESTIONS.

[11380.]—**East Anglian Sketching Tour.**—I want to spend a holiday on East Coast within easy range of some buildings worth sketching, and yet of a type of which every detail has been drawn and redrawn and utilised in a thousand modern buildings. Can any reader suggest a comparatively untrodden field within practicable distance from London, and accessible by rail?—SKETCHER.

CHIPS.

The New York city authorities will expend this year £156,000 in new asphalte pavement. The new pavement is to be laid down principally in the poorer quarters of the city.

M. Adrian Diaconu, an Hungarian architect and antiquarian, claims to have found in the ruins of the ancient Roman camp of Bersovia, at Bogsan, near Temesvar, unmistakable evidence that the Romans, and, in particular, the officers of the Fourth Legion (Flavia Felix), understood, as early as the second century, the art of printing, and made use of movable types while encamped at Bersovia. The reported discovery is said to be confirmed by two Bucharest savants and members of the Academy, after a careful examination of the proofs collected by M. Diaconu.

A sub-committee of the Lord Provost's Committee of the Edinburgh Town Council considered, last week, the additions and alterations necessary to be made on the Observatory on the Calton Hill, which is being taken over by the city from the Government. It was resolved to recommend the erection of a new dome for the large telescope at present accommodated in the temporary station at Murrayfield.

The Restoration Committee of St. Saviour's Church, Southwark, are making an appeal for a further sum of £8,000 to complete the restoration and rebuilding now in progress under the direction of Sir Arthur W. Blomfield. Of this sum, £3,000 is required for the works in hand at the nave and north transept, and £5,000 for the restoration of the choir and tower, while another £6,000 will be required at a future time for external repairs.

The new railway-station at Southampton West is making rapid progress towards completion. It is faced with red bricks, Portland stone being used for dressings. A feature of the frontage on the side next the town will be a clock-tower, carried to a height of 80ft. The contract for the building is being carried out for the London and South-Western Railway Company by Mr. H Lovatt, of Wolverhampton.

Legal.

NEW SEWERS.

THE London County Council, in its most progressive ardour, have sometimes found the vestries too slow in carrying out its requirements. The Council has not been backward in issuing orders to these ancient local authorities; but it has experienced difficulties in getting them obeyed. At last the question came before the law courts, as all these matters ultimately must do, and the London County Council failed in its endeavour. It is not possible here to go into the controversy as to whether a new sewer was or was not needed in this instance; but the decision of the Divisional Court of Queen's Bench in the case of St. George's, Hanover-square, is of much importance as a precedent for future use (*Times*, July 5). The point arose upon the argument on the application of the London County Council for a *mandamus* directing the vestry to comply with an order made by the Council in December, 1894, requiring them to construct a sewer as therein stated, and to execute certain works to join it to the main sewer as therein described. The vestry had refused to obey the council's order, and now the question was whether the Court would compel them.

The Court stated that the only point at issue was whether the Council, as representing the old Metropolitan Board of Works, have the power of directing vestries to construct such new sewers as to the council may seem needed. But it appears that although under the Metropolis Management Act, 1855, the old board was intrusted with various powers over sewers, but not with any absolute duty in this respect, upon the construction of the existing Act the judge laid it down that the County Council was not empowered to take the initiative by ordering specific new works of sewerage. They held that if new sewers are made, they must be made in such a way as the County Council approves. But they saw nothing in the statute to take away from the vestry its discretion as to making such sewers, and to leave it to the discretion of the Council. So the rule was discharged, and the London vestries still retain the right to decide when a new sewer is needed, and are not bound to comply with the discretion of the County Council in this respect, though if the work is to be done, it must be in such a way as the Council approve.

FRED. WETHERFIELD, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

K. J. S.—BUILDING.—DESIGN.—COPYRIGHT.—As this design has not been published, there seems no way of protecting it by registration as copyright. I do not know of any method by which a builder can be prevented from erecting a house, or doorway, or the like in exact imitation of one that has been already built, nor sued for damages.

S. S.—BUILDER.—QUANTITIES.—LIABILITY.—I don't see how you can be liable upon the clause quoted from your quantities. There is no gross negligence even alleged. The builder should have got an order for this work as an extra, and he does not appear to me to have any claim against you at all events.

LEGAL INTELLIGENCE.

DISCONNECTING GAS-METERS.—Thomas Dudley, architect and surveyor, Lancaster-place, appeared last week at Bow-street to a summons charging him with an offence against the by-laws of the Gas Light and Coke Company. Mr. Avory explained that the offence complained of was in contravention of Section 64 of the Company's Act, which provided that before any person connected or disconnected any gas-meter with the company's mains, he should give twenty-four hours' notice of his intention, or forfeit a sum not exceeding £5. The defendant had had his gas cut off no fewer than eight times in default of payment, and on one previous occasion he reconnected it without giving notice. The company, however, overlooked that offence. On May 6 the defendant's gas was again cut off, but on June 22 it was discovered that the meter had been reconnected. This was a serious offence, and people had been convicted of stealing the company's gas in similar cases. Evidence was called to show that when the gas at defendant's place was cut off, on May 6, the meter showed a consumption of 11,100ft. When a meter inspector visited the premises on June 22, he found that a cap placed over the cut end of the service pipe had been removed, and the pipe reconnected with the meter, which now registered 13,600ft. Mr. Johnson, on behalf of the defendant, said that the sheriff's officers were in possession of the premises. Everyone knew, he said, what sheriff's officers were like, and he suggested that they had connected the gas-pipes to enable them to smoke and keep warm. Defendant was well known, and utterly incapable of committing the offence attributed to him. Sir John Bridge said it was evident the defendant must have known that the gas-pipes had been reconnected, no matter by whom the work had been done. It was a serious offence, and he should fine the defendant £5; in default fourteen days.

London Building Act, 1894, Sec. 145. — At Southwark Police-court, on the 11th inst., Mr. H. A. Hardy, of 6, Nebraska-street, Great Dover-street, S.E., and Mr. J. Malham, of 140, Rockingham-street, S.E., were summoned by Mr. Bernard Dicksee, district surveyor for East Newington, for erecting a w.c. in the rear of 56, Great Dover-street without giving notice as required by Sec. 145. Mr. Dicksee, in his evidence, stated that on June 24 he discovered the building in question had been erected, no notice having been given to him. He made inquiries, and ascertained that Mr. Hardy had executed the work for Mr. Malham, who found his own materials. He (Mr. Dicksee) therefore contended that Mr. Hardy was "the builder," and Mr. Malham the "other person causing or directing the work to be executed," and that they were both liable to the penalty. Both defendants pleaded ignorance of the fact that notice was required. The work had been ordered by the sanitary inspector, and they had merely carried out his order. Mr. Dicksee said that was his reason for taking out the summonses. There appeared to be misconception among builders on this point. He had great difficulty in getting notice from the builders when work had been ordered by the sanitary inspectors. He had, therefore, taken these proceedings to warn builders that notice must be given in these cases. He did not, however, wish to press for a large penalty, but thought a nominal one would be all that was necessary. Mr. Kennedy said that it was a matter of very great importance that notice should be given to the district surveyor in all cases. He adopted the district surveyor's view, and imposed a nominal fine of 5s. and 5s. costs on each defendant.—Mr. W. H. Cable, of 176, Malden-road, N.W., was also summoned for doing work to 170, Great Dover-street without having given notice. Mr. Dicksee explained that this was a similar case, but that the work ordered by the sanitary inspector was contrary to the Building Acts, and the irregularities were now being amended. The defendant's solicitor thought that, as only two wooden walls of a w.c. had been removed and replaced with brick, the work was only a necessary repair, and exempt under Sec. 209. Mr. Dicksee pointed out that, even if the work were a necessary repair, it was not exempt, as only those necessary repairs that do not affect an external or party-wall were exempt, and these walls were external. Mr. Kennedy ruled that the work was not exempt, and that notice was necessary, and he fined the defendant 5s. and 5s. costs, as in the previous case. Messrs. Hart Bros., of 16, Great Dover-street, was also summoned for doing work to 17, Great Dover-street without having given notice. Mr. Dicksee stated that the work consisted of taking down and rebuilding the parapet of back wall. Defendants pleaded ignorance of the necessity of giving notice. Mr. Dicksee explained that a misconception might have arisen in consequence of the decision of "Briant v. Fletcher," under the Metropolitan Building Act, 1855, but that this decision had been wiped out by the London Building Act, 1894. Mr. Kennedy held that notice should have been given; but as there might have been some misconception, he would only impose the same fine as in the other cases, 5s. and 5s. costs.

Lavy and Upjohn v. the London County Council.—This was an appeal on Tuesday before Lords Justices Lindley, Lopes, and Rigby, from a decision of Mr. Justice Day and Mr. Justice Wright, sitting as a Divisional Court. The decision of the Divisional Court was given on a case stated by a Metropolitan police magistrate. Upon July 24, 1894, the appellants were charged with having, at 391, City-road, in the parish of Islington, in the county of London, unlawfully erected a certain structure beyond the general line of buildings in City-road without the consent in writing of the London County Council, contrary to section 75 of 25 and 26 Vict. cap. 102; 45 Vict. cap. 14, section 10; and 51 and 52 Vict., cap. 41. By the Metropolis Management Amendment Act, 1862 (25 and 26 Vict., cap. 102), section 75, it is enacted that "no building, structure, or erection shall, without the consent in writing of the Metropolitan Board of Works, be erected beyond the general line of buildings in any street, place, or row of houses in which the same is situate, . . . such general line of buildings to be decided by the superintending architect." By section 28 of the London County Council (General Powers) Act, 1890 (53 and 54 Vict. cap. CCXLIII.), "any person deeming himself aggrieved by the certificate of the superintending architect may, within 14 days after notice of such certificate has been given or served, appeal to a tribunal to be constituted as in the section mentioned." The facts were as follows:—The appellants were the owners of the house 391, City-road, which was 38ft. from the footway. It had a forecourt which for many years was bounded by a brick wall, 2ft. or 3ft. high, 9in. thick, with an iron railing 5ft. 6in. in height. That being the state of things, the appellants from time to time made applications for leave to build upon the forecourt. The applications were refused. Prior to 1894 the appellants erected on the dwarf wall a hoarding for advertising purposes. It was placed against the railings so as to get their support, and it had struts for additional support. The County Council gave notice to remove it, and on May 5, 1894, the hoarding was removed and replaced by what was now complained of—viz., a wall 11ft. high, 14in. thick, with its face put back 4½in. from the line of the old dwarf wall, so that there might be a ledge to support it. The summons was taken out on July 11, and on July 13 the architect gave his decision, under section 75 of 25 and 26 Vict., cap. 102, as to what the building line was. That decision was appealed from. On July 24 the appellants appeared to the summons, and the respondents asked for an adjournment. The adjournment was granted upon the terms that the rights of all parties as they were on July 24 should be preserved—*i.e.*, that the matter was to be in the same position as if the magistrate had begun to hear the appeal on July 24. Adjournments took place from time to time, and on October 19 the architect's decision was confirmed by the appellate tribunal. By that confirmation the building line was finally decided to be the line of the house 391, City-road. The magistrate found that the wall was erected as an advertising station, but that it was intended to serve also as a boundary wall for the forecourt, and on December 7 made an order upon the appellants to demolish the erection, and found, so far as it was a question of fact, that it was a structure in front of the general line of buildings. No consent to the erection being made was ever given by the respondents, the London County Council. The learned justices of the Common Law Division overruled a technical objection on the part of Messrs. Lavy and Upjohn that the architect's decision had not been given at the date of the issue of the summons. They also held that the wall in question was a structure or erection within the meaning of the prohibition, and gave judgment in favour of the County Council. The owners appealed. The Lords Justices agreed with the learned Judges in the Court below, and dismissed the appeal.

Timber in Party-Walls.—At the Uxbridge Petty Sessions on Monday, Messrs. Wilkinson and Son, builders, &c., of Notting-hill, who did not appear, were summoned by the Uxbridge Rural District Council for unlawfully placing timber in party-walls in two buildings erected by them at Northwood, thereby infringing by-laws Nos. 31 and 32 of the said Council. Mr. B. Freeman, surveyor to the Council, gave evidence to the effect that plans were submitted in the early part of the year by Messrs. Pinchbeck, architects, for several pairs of houses in Hallowell-road, Northwood, and were duly approved by the Council. There was no timber in the party-walls marked on the plan. According to No. 31 of the by-laws, it was stated that no bond timber or plates were to be placed in the party-wall. By-law 32 stated that there should be 4½in. from the centre of the wall to the joists. The party-wall between these two houses in question is only 14in. up to the top story. On the first and second floors the joists were put into both walls. That was an infringement of the by-laws. Witness had interviewed Mr. Wilkinson since the proceedings had been instituted, and the defendants were cutting out the joists. He was instructed to press the charge against the builders, as it was a very bad case. The Bench also took this view, and fined the defendants the full penalty of 40s.

Re George Beszant, the younger, Melksham, Builder. — The liabilities in this case were £698 1s. 5d., and there was a deficiency of £628 6s. 2d. The debtor has been adjudged a bankrupt, and the Official Receiver is trustee. He reported as follows: The debtor has, since 1888, carried on business as a builder, commencing with no capital. He alleges the cause of his failure to be simply "bad speculation in building at Melksham." He admits that he first became aware of his position two or three years ago, and has since contracted debts to the extent of £150 or £200. According to the statement of affairs, however, this amount is nearer £400 or £500. He appears to have executed a deed of assignment on the 2nd of March last, and this was the act of bankruptcy upon which the receiving order was made. The trustee under such deed has accounted to the Official Receiver for the stock, furniture, and book-debts realised by him. The sum entered in the statement of affairs should be less by about £11, certain of the costs incurred by the trustee in realising, which were deducted. It is expected that the liabilities will be increased, as the securities held by a partly-secured creditor do not belong to the debtor but to his wife, and she may probably have a right to prove against the estate.

Our Office Table.

The Turners' Company announce that their twenty-sixth annual prize competition in turnery will be held at the Mansion House, London, by permission of the Lord Mayor, on the 23rd, 24th, and 25th of October next. Prizes in money, medals, certificates, and, in the highest classes, the freedom of the Company will be presented to the successful candidates according to merit. The competition will be in turning in hard and soft wood, xylonite, celluloid, vulcanite, and other materials, and there will be special classes for apprentices, amateurs, and schoolboys. The qualities considered in awarding the prizes will be beauty of design, symmetry of shape and utility, and general excellence of workmanship, fitness of the work for its intended purpose, good copying, novelty, and polishing, carving, and inlaying. The exhibits must be delivered at the Mansion House in the week ending October 18th, and the judges will be Mr. J. J. Holtzapffel, Mr. Alfred Bevan, Mr. W. Brindley, and Mr. A. Murray, City Surveyor.

At a meeting of the Liverpool branch of the Sanitary Inspectors' Association, held on Saturday last, Mr. Henry H. Spears (inspector of nuisances for Waterloo-with-Seaforth) read a paper entitled "A Layman's Notes on Sanitary Law," in the course of which he argued that the existing nuisances clauses in the Public Health Act were inadequate to deal with nuisances where structural alterations were necessary. He, therefore, advocated a reform of the Sanitary Law to something like that of the Isle of Man Local Government Act, 1886, which empowered local authorities, without the intercession of magistrates, to carry out or cause to be carried out any structural alterations which, in the opinion of such local authority, were necessary to insure the health of the inhabitants.

In a report on the hygienic virtues and shortcomings of wood pavement, Dr. Blyth, the Health Officer for Marylebone, refers also to asphalte, which he is inclined to prefer, on the ground of its being less capable of absorbing the impurities of a busy thoroughfare. Its chief drawback, however, as he observes, is its noisiness. The sharp pit-pat of the horses' hoofs is almost as annoying as the rattle and roar of the traffic over granite cubes. "In the near future, however, when that unfortunate Locomotive Act, 1865, is repealed, and the great industry in self-propelling carriages by compressed air, by petroleum and electricity, is in full swing, the hansom cab, the omnibus, and all light carts will disappear from the streets, motors in the long run being much cheaper and more convenient; in that happy time this objection against asphalte will not hold good."

"The Year-Book of Australia" points out that Australian hard woods are now in much request in Europe for wood-paving purposes, and large orders have been received in Tasmania and elsewhere for cargoes for the United Kingdom. Any introduction of inferior timbers into the home market would doubtless retard, or, perhaps, altogether stop, the business, and, according to the *Year-Book*, much of the Tasmanian wood is greatly inferior to the best classes of New South Wales timber. Messrs. Burns, Philp, and Co. have had samples of the best timbers in London for some years; but prices quoted by them were hardly as low as the quotations of other colonies for inferior woods. Some weeks ago, however, orders were cabled out to load three vessels, equal to 600,000ft. each vessel, to be despatched monthly from Sydney. Unfortunately, these orders could not be executed, as the milling plant on the New South Wales coast was not adequate to turn out such a quantity, and very great extension will be necessary before quantities like this can be dealt with. A shipload is, however, on its way to London, and the firm named are seeking to gradually build up a large trade by sending only the timber best adapted for wood-block pavements.

Messrs. T. Crapper and Co., of Marlbro' Works, Chelsea, have issued a new catalogue of the sanitary appliances made and supplied by them. It comprises their well-known air-tight manhole covers, air inlet valves, cast-iron and porcelain baths, cast-iron pipes and junctions, elastic valve closets, enamelled fireclay sinks, grease traps, &c. The improved Kenon disconnecting trap suggested by Dr. Corfield is also shown. The catalogue is very well got up, copiously illustrated, and the prices are in all cases moderate.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2116.
◆
FRIDAY, JULY 26, 1895.

THE STYLE FOR A NEW CATHEDRAL.

IF the Liverpool Cathedral is in abeyance for the present, and the Birmingham one postponed, perhaps, to better times, there are two of which something is now being heard. The first is the Catholic one at Westminster, the other is presumably Anglican, and is in contemplation at Washington. What seems to interest the public, in each of them, is its style—style is about as far as the public usually get, in their attempts to judge of a new building. Few people, indeed, can be brought to see that there is anything beyond it. Plan, proportion, composition, detail, do not force themselves on the notice of the uninstructed; but even the man who reads nothing but newspapers and novels can see a difference, say, between St. Paul's and Westminster Abbey. It is like the difference between a Greek book and an English one, which would have been plain even to the little boy who, as he said, knew his letters very well, but had not learned the names of them yet. Such a little boy, as to architectural matters, it usually is who employs and directs and criticises the architects of the day. Possibly it is a set of such little boys—of all ages—who are the trustees of the proposed Washington Cathedral, and who have asked an architect, Mr. Flagg, to report to them on the subject of style. His statement in reply contains, as is natural under the circumstances, some rather elementary teaching, and in addition to this some very questionable assertions.

That Gothic architecture began to be copied in the United States about fifty years ago, and that it never has been copied there with any great success, are the undoubted facts which Mr. Flagg sets out. And when he goes on to trace the original development of Pointed art, he only says what has been said a great many times before. It amounts to this. "The olden builders wanted to make their churches fireproof. To do so, they vaulted them in brick or stone. They could not vault them unless the spans were narrow and the supporting columns numerous, and out of their structural incompetence in these respects arose all the peculiarities of Mediæval churches. We can now do our fireproofing in easier and cheaper ways; therefore let us give up Gothic, and"—here comes an extraordinary *non sequitur*—"let us build in Renaissance."

Now, first of all, we question the assertion that it was simply, or even chiefly, to make their churches fireproof that the ancient masons vaulted them. Vaulted and domed buildings had been in use a thousand years earlier than the Gothic period. Without going back to the corbelled stone coverings of early Greek treasuries, vast Roman works had been executed—not in Italy alone—without any structural timberwork in them. Every pilgrim to Rome saw the Pantheon and the remains of even mightier things; every Crusader who passed by Constantinople gazed on St. Sophia. Before Gothic arose, the Saracens were building their domed and vaulted mosques; the Greek Christians their domed and vaulted churches. Men had for ages felt it to be a condition of the highest type of architecture that it should be roofed in the same materials with which it was walled. Nothing else is so masterly; nothing else is so permanent; nothing else is so monumental. Any tiro can cover his spans with wooden trusses, or with iron ribs, now they are in the market. That shows no skill, no power, no art. But it takes more than a tiro to build the smallest bit of vaulting; and the production of a vaulted building was the criterion of an architect.

This had never been quite forgotten. But constructional science had more and more died out from the eighth to the tenth century. There was a general belief that the world would end in the year 1000, and people felt, therefore, that it did not matter how badly all secular work was done. Probably they got into the state of mind which was attributed to a certain D.D. who flourished some 30 years ago, and who predicted that the earth would be swept away by a comet at a date now long since past. A fortnight before the time named, it was announced that the reverend gentleman was having his coals in by the scuttle, which was probably an exaggeration, though he belonged to a race noted for prudence and economy. The tenth century people, however, did build, even if they did not live, in this hand-to-mouth fashion. They began the century with the conviction that the universe itself had only a 99 years' lease, and they did not attempt to make their churches more durable than the globe on which they stood. Craftsmanship was almost forgotten, and had to be revived out of barbarous ignorance when the scare was over. But one thing lasted through it—the habit of building on the basilican plan. When men took heart again, found that life had still to be lived, and learned once more, by slow degrees, how to live it, it was to the old long-aisled type of plan that their efforts at improvement were directed. It did not get its narrow avenues and its multitude of columns from the necessities of groined vaulting: they existed twenty generations before groined vaulting arose. They belonged to the type on which the churches of Western Europe were mainly based from the beginning—that is, to the Roman basilica.

What happened in the 12th century was not chiefly a fright about fires, and a wild desire for fire-proofing. Perhaps, indeed, the architects of those days, like those of our own, finding that their clients had more respect for "practical" than for artistic considerations, used the practical ones to influence them, when all the while it was the artistic ones that influenced themselves. Perhaps they said, and said truly, if your church is vaulted everywhere, it cannot be burnt down like that in such and such a city, or at such and such an abbey. But what they were themselves thinking of was apparently more like this: "Christianity has become the greatest power in Europe; its buildings should be the most imposing, permanent, and striking. We are outmatching the secular castles with our church-towers; we will surpass the old temples with our church interiors. The best that man can do in building is what we will do; and this best, as all nations know, is to span them, as well as to wall them, with stone." Does anybody to this day, know a better "best"? How long will the "fireproof" buildings last, which, Mr. Flagg says, can be erected "for a tithe of the time, labour, and trouble" of the old Gothic ones? Their permanence, happily, is not likely to be much in excess of their beauty. If they do not burn down, as so-called "fireproof" buildings are notoriously apt to do, they will perish through rust, or crack themselves to pieces by the unequal expansion and contraction of their materials. There will be "many dry eyes" when they finally crumble away.

But how does all this praise of modern fireproofing show the superiority of the Renaissance style? The Great Renaissance churches, which succeeded the Gothic ones, were, like them, spanned with stone, and not covered in on Puff's Patent Fire-Defying System. If the Gothic naves were spanned by cross-vaults, the Renaissance ones also were spanned by cross-vaults, barrel-vaults, and domes. In construction, they were vastly heavier than their predecessors. If, as Mr. Flagg supposes, Gothic churches were obliged to have so many columns because they were vaulted—Renaissance ones would have had a great many more, for their columns had a far heavier load to carry. But the fact is, that Gothic churches could easily have been built with much wider naves, and much fewer columns than we generally find in them. More than this—a great many of them were so built. St. Bertrand de Comminges was nearly 50ft. across the nave, and had no aisles. The cathedral of Alby is 63ft. across, from centre to centre of the piers. Tarragona Cathedral nave is 52ft. across from centre to centre, the Collegiata at Manresa is nearly 60ft., and Palma Cathedral more than 60ft., and the width of the bays, or, in other words, the fewness of the columns, in some Gothic churches is equally remarkable. At the Jacobins, Toulouse, the nave piers longitudinally are 30ft. from centre to centre. At St. Antholin, Medina, they are at the same distance. At the "New" cathedral of Salamanca they are 33ft., at Avila Cathedral 34ft., at the Collegiata of Manresa 32ft., and at Siguenza Cathedral 39ft. What has been done so often could be done again, so that Mr. Flagg's "practical" reasons against Gothic clearly will not bear looking into.

He has a real reason, however, in the fact that Gothic has not been taken up with much success in America. But has Renaissance been followed there any more successfully? It hardly seems so, from the plans and views which find their way to Europe. The most interesting things in them are the American ones: the ideas, sometimes barbarous, sometimes incongruous, but sometimes fresh and suggestive, which our fellow workers on the other side of the Atlantic have infused into that collection of odds and ends, which, under the name of Renaissance, is just now in fashion. Yet somehow the style does not seem so pliable in their hands as the Romanesque which they previously began to develop. In that they often took a line of their own, and did something at once natural and artistic. In Renaissance, their power to do that seems enfeebled. Most of it, apparently, is the same sort of thing of which we are getting sick in London: a mere product of caprice, without reason, without aim, without soul. We shall be rid of it soon, as probably they will, likewise: it would be a pity to begin a cathedral in a style which everybody will have seen through and despised before the walls are up to the level of the roof.

In Mr. W. Flagg's remarks on types of planning we observe with more pleasure an echo of much that has appeared in the BUILDING NEWS during the last quarter of a century. But plan and style are quite independent things. Unobstructed areas may be found in ancient Byzantine, Romanesque, and Gothic buildings, as well as in Renaissance ones. The dome itself was incorporated into one variety of the Pointed style which flourished late in the 12th century in Central and Southern France. It was adopted with equal success in the refined Romanesque of Spain; for instance, at Salamanca, at Zamora, and probably at Toro. We have precedents for all we can want, if anybody is still foolish enough to look on precedents as something sacred. To the wise architect they are far enough from sacred, though they are in the highest degree valuable. They are, in fact, somebody else's experiments, tested by time and change, so that we can now see easily where they were weak and where they were strong, where they succeeded and where they failed. The Renaissance style, like others, has precedents for us of this sort—works to study, to criticise, to improve on. We hope it is frankly in this spirit that the Renaissance which seems to have been decided on for the Washington Cathedral will be treated.

Unless it is so, it would have been far better to leave the question of style an open one.

ARCHITECTURAL LANDSCAPE.

LIKE other allies of architecture, gardening was once closely associated with all the greater achievements of the constructive art. Italian, French, and Dutch gardeners tried to surpass one another in adding to or accentuating the charms of their great buildings, or in furnishing an appropriate setting to them. A true *esprit de corps* animated both architects and gardeners, and their joint productions even inspired the great school of Classical landscape painters of whom the names of Claude of Loraine, R. Wilson, and Turner are most prominent. Grandeur, breadth, and stateliness are characteristic qualities of the works of these masters, and we have a few painters amongst us now, chief among them being Mr. John Fulleylove, who are devoted exponents of the artistic alliance between architecture and scenery. The architectural "landscapist" has not, however, a numerous following; even those who make our architectural perspectives are strangely ignorant of the first principle of the art of uniting buildings with their surroundings, for do we not see every day of our lives small villa residences surrounded by long, winding carriage-drives amidst park-like scenery; or a building set down upon a plain, dotted over by a few straggling trees, reminding us of a house-agents' litho', or a cemetery mason's landscape? The architectural perspective is, in fact, a sorry witness to the want of sympathy between the architectural and the landscape elements of design. Each ought to contribute to the other, as it is their joint effect which makes for the result. The architect will never properly appreciate this alliance till he begins to design *in situ*, instead of confining his attention to the drawing-board, or of studying a building on paper only. The practical, specialising spirit of the day has something also to answer for in restricting the architect's attention to the building, and regarding the site and environments as accidental. The divorcement of gardening from architecture has been rendered more complete by this limitation of the architect's studies. Nor do we find any programme or syllabus of the young architect's studies in which landscape in relation to the building has found a place. The "landscape gardener" is a profession followed only by a very few—in fact, the art has of late years passed out of general recognition, or is assumed by every head-gardener, land steward, or nurseryman. We have not now men like Repton, Brown, Loudan, or Paxton, who devoted their whole time to the design and laying-out of parks and noblemen's estates, and who at the same time often became accomplished as architects, or who were jointly and simultaneously engaged with them in the carrying-out of great works. In those days mansions were not built anywhere on vacant sites, and then allowed to be spoilt by the taste of the estate gardener or nurseryman; but the site was selected and its surroundings artistically arranged by a landscape gardener of eminence. The approaches and carriage-drives were planned in relation to the aspect of main front and entrance, and also to the "lay" or levels of the ground, and the position of the main clumps of trees. The greatest skill and tact, though not always in good taste, were displayed to avoid the visible direction or course of the approach by judicious bends and the planting of clumps, in addition to which, the style of the building was ordered to some extent by the character of the scenery and the prevailing forms of the foliage. Near the main front of the building the art of the gardener was directed to lead the eye by gradations from the rougher and more natural outskirts to the smooth lawn and artificial platform and terraces, and here the geometrical style of gardening and the ornamental taste of the florist came into play. The trim lawns and flower-beds naturally brought the art of the gardener down to the very windows, or into touch with the building, and was a fitting climax. Beyond the flower-garden, smaller shrubs and trees of an ornamental kind formed a transition to the park. The accessories of balustraded terraces, flights of steps, pedestals, and vases would bring down the more solid masses of the building, and connect them with the grounds. No sudden transition marked the one from the other, such as we see in many modern villas which rise abruptly from the midst of smooth lawns or small forests of trees, as if they fell from the clouds on the most uncongenial of surroundings. What can be more grotesque than to see a house designed like a miniature Italian palace built on a wild or rugged hillside, or a picturesque group of buildings planted in a flat and tame landscape? The one is as incongruous a misappropriation of style as the other. We do not mean to say we want tame buildings on tame sites, or picturesque ones on rugged sites; but we expect to see a little affinity between the building and its surroundings, some art bestowed on the platform, so that the contrast may not be so abrupt as to cause one to exclaim, "What a caricature! How strangely out of place!" And it is just this endeavour of harmonising the building to its environments, of making the gradation easy and natural, which can be found in all our great historic buildings. We find nothing jarring or discordant between the buildings and surroundings of our great ancestral houses and palaces. The Palladian severity of Wollaton, and the broken and picturesque Italian of Blenheim, appear to be in entire harmony with their natural setting. The noble house of Hatfield, with its projecting wings and corner turrets, and its terraced sides, seems as if it had grown up amidst its beautiful surroundings naturally. Again, the picturesque and turreted skyline of Burghley is in perfect harmony with the landscape around it, the multiplicity of its vertical features, and the light and shadows of its broken plan being in keeping with this class of scenery. Let us take Longleat as another type of English house of Elizabethan character, surrounded by a natural style of planting. Few who have seen it will deny a charming appropriateness of this style to the round-headed foliage of the trees. Besides our Domestic buildings, we have the examples of our great churches. How majestically does the great cathedral of Peterborough stand out from the dead level of the locality; or Ely on the flat ground of Cambridgeshire; and then let us contrast with these the western front of Durham, rising on its wooded heights above the Wear—all three admirable examples of the relation of structure to landscape. What would be appropriate to the Fens would scarcely be suitable to Wales or the Lake District. The majestic towers of Ely break the flatness of the surrounding landscape; but it has sufficient length of nave and repose of horizontal lines to unite with the scenery. A fitful, spasmodic, broken skyline would be wanting in harmony in such a situation.

The value of material in this connection must not be forgotten. There is a natural affinity between building materials and the locality. In a stone district, like Northamptonshire, brick or timber-framed buildings would be out of place. The old stone-built mansion in the style of the Renaissance, like Kirby Hall, is thoroughly in keeping with its situation. So, too, we can appreciate the brickwork of the Eastern counties, and the half timber-framed work of Shropshire, Surrey, or Kent. The timber-framed houses which abound in the towns and villages on the Moselle are picturesque examples of the relation of material to locality. Everywhere, from the feudal castle which crowns the rocky crag, above vine-clad slopes, like the Castle of Elz, near Moselkern, with its medley of gables, turrets, and dormers, to the reposeful châlet on the banks of a Swiss lake, we find the natural adaptation of material and feature. It is needless to give further instances. The chief lessons we learn are of value to the architect. One is appropriateness (*a*) of building to contour or configuration of ground, and (*b*) of style of building to the character of scenery or of foliage, and in attaining this attribute the principles of contrast and gradation come into play, just as we wish either to accentuate or smooth down the differences. With respect to the first condition—contour of ground or of level—one writer (Mr. W. Robinson, the author of "Garden Design") says the natural form or lines of the ground are the best to follow, and he says: "The lawn is the heart of the true English garden, and is as essential as the terrace to the gardens on the steep hills," and he illustrates this by the fine Elizabethan house of Wakehurst, where the grounds are not terraced, but the lawn goes right up to the base of the house. At Arundel Castle, terracing is introduced, which is rendered necessary by the fall of the ground. The objection raised to terrace walls is that they cut off the view of the landscape from the house, or the house from the landscape in some cases—but if properly planned this need not be. What we have said just now on this point is worth repeating—viz., the terraces and other outworks of the building are valuable, as at Haddon, in gradually leading the eye from the more natural scenery or park to the garden. The late Sir C. Barry's idea, quoted in "The Formal Garden," is that the "garden was gradually to become less and less formal till it melted away into the park." This is the right idea. We cannot agree with the adherents of the formal style of gardening, as expressed by the author of the book we have mentioned, when he tells us that the garden should be separated from the adjacent country "by a clean boundary line, a good high wall for choice." No doubt there may be circumstances which warrant such a distinct separation of the garden from the country, but it does not apply in all cases. As to the character of foliage and scenery, it ought to control to some degree the style and features of the building; a hilly or precipitous locality suggests a style a little in harmony with it, as a flat, tame landscape would dictate a few bold features.

Upon the Dutch or formal style of gardening, as distinguished from the natural style of landscape gardening, we do not propose to say much. The beauty of old gardens like those of Compton-Wynyates, Levens Hall, Montacute, Haddon, Brympton, and others speak for themselves. We think that in every true design the formal and the natural should find a place; the one may merge into the other, or be distinct parts of the whole. Reproducing uncultivated nature is by no means the aim of the true landscape artist—far from it; it is rather the idealisation of Nature that he seeks—not Claude-like landscapes, but English pastoral scenery idealised Even lines of "tortured" limes such as we see in French towns are in harmony with stately architecture. We can admire such things as clipped yews at places like Versailles or Hampton Court, though some of the grotesque forms are ridiculous abortions. There will always be two sides to every question. We have naturalists and formalists not only in gardening, but in painting, ornamentation in architecture, and in almost every other thing, and it is equally certain there is truth to be found in each view. It is as great a mistake to imitate uncultivated nature near our buildings as it is to affect an admiration for curved, crooked, or serpentine paths because they are supposed to be natural, or to ignore a straight line because Nature never shows one. Studied picturesqueness is quite as absurd as the attempt to turn our gardens into geometrical puzzles.

DEFECTS OF MODERN HOUSE ARRANGEMENTS.

DURING a season which until the last few days has been exceptionally dry, the sanitary condition of houses and dwellings in every great town must create some concern. An abnormally dry season is one looked upon with some suspicion by hygienists and medical authorities. It means, of course, a sparse and impure water supply and a sluggish discharge through the sewers. Under these conditions of dryness and temperature all kinds of apprehensions are entertained. The machinery of the Local Government Board is set in motion, a fussy local board or vestry busies itself, and the least hint or suspicion of something wrong arouses the meddlesome action of the sanitary inspector. The power given under the new law is to make him more arbitrary than discreet. Then every medical practitioner is under a penalty to make notification of any case of a questionable character among his patients, and something like this is what happens:—A person is taken ill, and sends for his doctor; is found to be suffering from some febrile disorder, or slight gastric derangement, and forthwith his name and address are notified to the sanitary authorities. The drains are at once suspected, especially if they are arranged on the old system. A sanitary inspector makes his appearance on the scene; he examines the drains, and their house connections, the water supply, &c. He applies the "smoke" test to the drains, and discovers a leakage that has been going on, perhaps, for years, and forthwith condemns the whole system. Both landlord and tenant are pounced down upon with merciless severity, as if other houses were not in an infinitely worse condition, and had been allowed to remain so for years without any serious consequence. All the time a street-grating near the house may have been giving out sewer-gases enough to poison the whole street, yet it is passed by uninspected, or the ventilating-pipe of an adjoining house may have been discharging the same deadly gas. In a desperate attempt to put the law into operation trivial faults are discovered; all the while the real evil may go undetected. That this is often the result of the existing regulations may be well imagined. Again, there is a prejudice against all those houses which have not been drained on the regulation model. The inspector at once comes to the conclusion that there is a faulty connection between the sewer and the house; that the traps are defective; or that there is no ventilation—in some instances all hasty conclusions. The modern house-owner is often victimised: he is called upon to reconstruct the whole drainage system, to remove the old fittings and substitute ones of improved make and in accord with the regulations of the sanitary authority, but without any absolute proof that there is any leakage, or that his drains and fittings are more defective than hundreds of others in the neighbourhood. And why? Because his tenant is suspected of having an infectious illness. Such is by no means an exaggerated picture of hundreds of cases where the unsuspecting house-owner is made the victim of vexatious sanitary regulations. Of course, there is the other side of the picture, where the law steps in to compel indifferent and negligent house-owners to put their property in a sanitary condition, and it is because this class is more numerous that we have the hardships inflicted by a non-discriminating department of sanitary officials. The Public Health Act, 1875, was enacted to compel property-owners and others to provide sanitary dwellings amongst other things; it was to make people sanitary who otherwise would not be. Further instalments of the law like the Public Health (London) Act, 1891, have made it still more arbitrary and indiscriminating in its operation, so that those who have good fittings, though out of date, are treated similarly to those whose sanitary arrangements are of the worst order.

But the health of our houses depends on other things quite as much as on the number of patented fittings of a certain approved pattern, disconnecting traps, manholes, and the regulation plan of connecting house with sewer. These are useful and necessary in some cases; but they do not supersede the value of periodical flushing of house-drains, which in this dry weather is absolutely necessary for health. A bad case of the want of flushing and inadequate water supply is now being investigated. Several admirable flush tanks are made—such as Crapper and Co.'s automatic. Where the falls of the drains are small, the daily flush is the best safeguard that can be provided. The very dry season calls urgent attention to the question of the level of the ground water under dwellings—a point often lost sight of in estimating infected areas. During excessively dry weather like the present, the ground-water level will be low, and the interstices of the soil above be filled with air and gases of very questionable character. Old refuse heaps and ashbin contents are the kind of soil which whole suburbs of London are built on, and it is therefore not surprising if such a substratum of soil should give off gases of a dangerous kind. One provision has been made by building by-laws which, if properly carried out, effectually cuts off the ground air and moisture from the building—namely, the laying of a bed of concrete over the whole area; but as to the manner this is done, or the nature of the concrete, we have little positive proof in thousands of cases of small dwellings erected by jerry builders. What is equally important as an additional safeguard is a free space of air at least 18in. in depth, open to the external air by perforations or air bricks, below the ground-floor joists of rooms above the ground level or concreted surface, not a mere subterfuge of a few inches deep filled up with sleeper walls, and having only a few air-bricks in front. If there are cellars with properly made windows, well and good. When the level of ground floor is too low to allow of a good air-space, we should insist on continous dry areas being formed in front and back of all street houses, these being properly concreted and asphalted. In addition to these sanitary provisions the hygienic house of the future demands that it should possess a general system of ventilation. Such a system should be self-acting, simple, and natural, and be easily applied without much expense, which essentials appear to be most nearly fulfilled in Messrs. Boyle and Son's method. A sanitary house should be so planned and constructed that not only should it have the means of quickly and innocuously getting rid of all its waste products, but of also being able to change its air continuously summer and winter during every atmospheric condition. The healthful state of our town dwellings will not be materially improved until, firstly, the drainage and ground air and moisture are cut off from the house; secondly, till efficient flushing arrangements are provided during dry weather; and, thirdly, till an automatic system of ventilation be made compulsory.

OUR HOMES.

By R. BARRY PARKER, Architect.

(*Continued from p.* 99.)

A MOST delightful house can be designed with a hall, one other good large room, kitchen, and offices. But many of the most thoughtful of our times have come to feel that even a house of this size, though possessing advantages, is not really worth what it costs them to maintain, costs them in worry, anxiety, loss of liberty, incessant bother with servants, and in time spent in work entirely without interest, dignity, or real advantage to themselves or their fellow men, or power of giving any vestige of pleasure. These have come to see how much of what we have grown to regard as necessary is really only waste; and when we think of the number of unused and useless rooms there are in every town, village, and hamlet in the country, of the number of unused and useless things in those rooms, and the amount of unproductive labour expended daily in their creation and maintenance, we can only wish that more and more may come to realise this.

But perhaps there is nothing which contributes more to the artistic failure of our rooms than the look everything has of being ready to move at any moment. Most things, to look right and happy in their places, must be designed for their places.

In the little illustration of an overmantel, used a while back, the frame with three panels in it would have had to be made the width of the chimney-breast against which it was to be fixed; if it had been wider or narrower it would not have looked nice—that is, it must have been designed for its place. This is one of the secrets of its superiority over the overmantel substituted for it. That overmantel could not, of course, look nice anywhere or anyhow; but this is one reason why it could not.

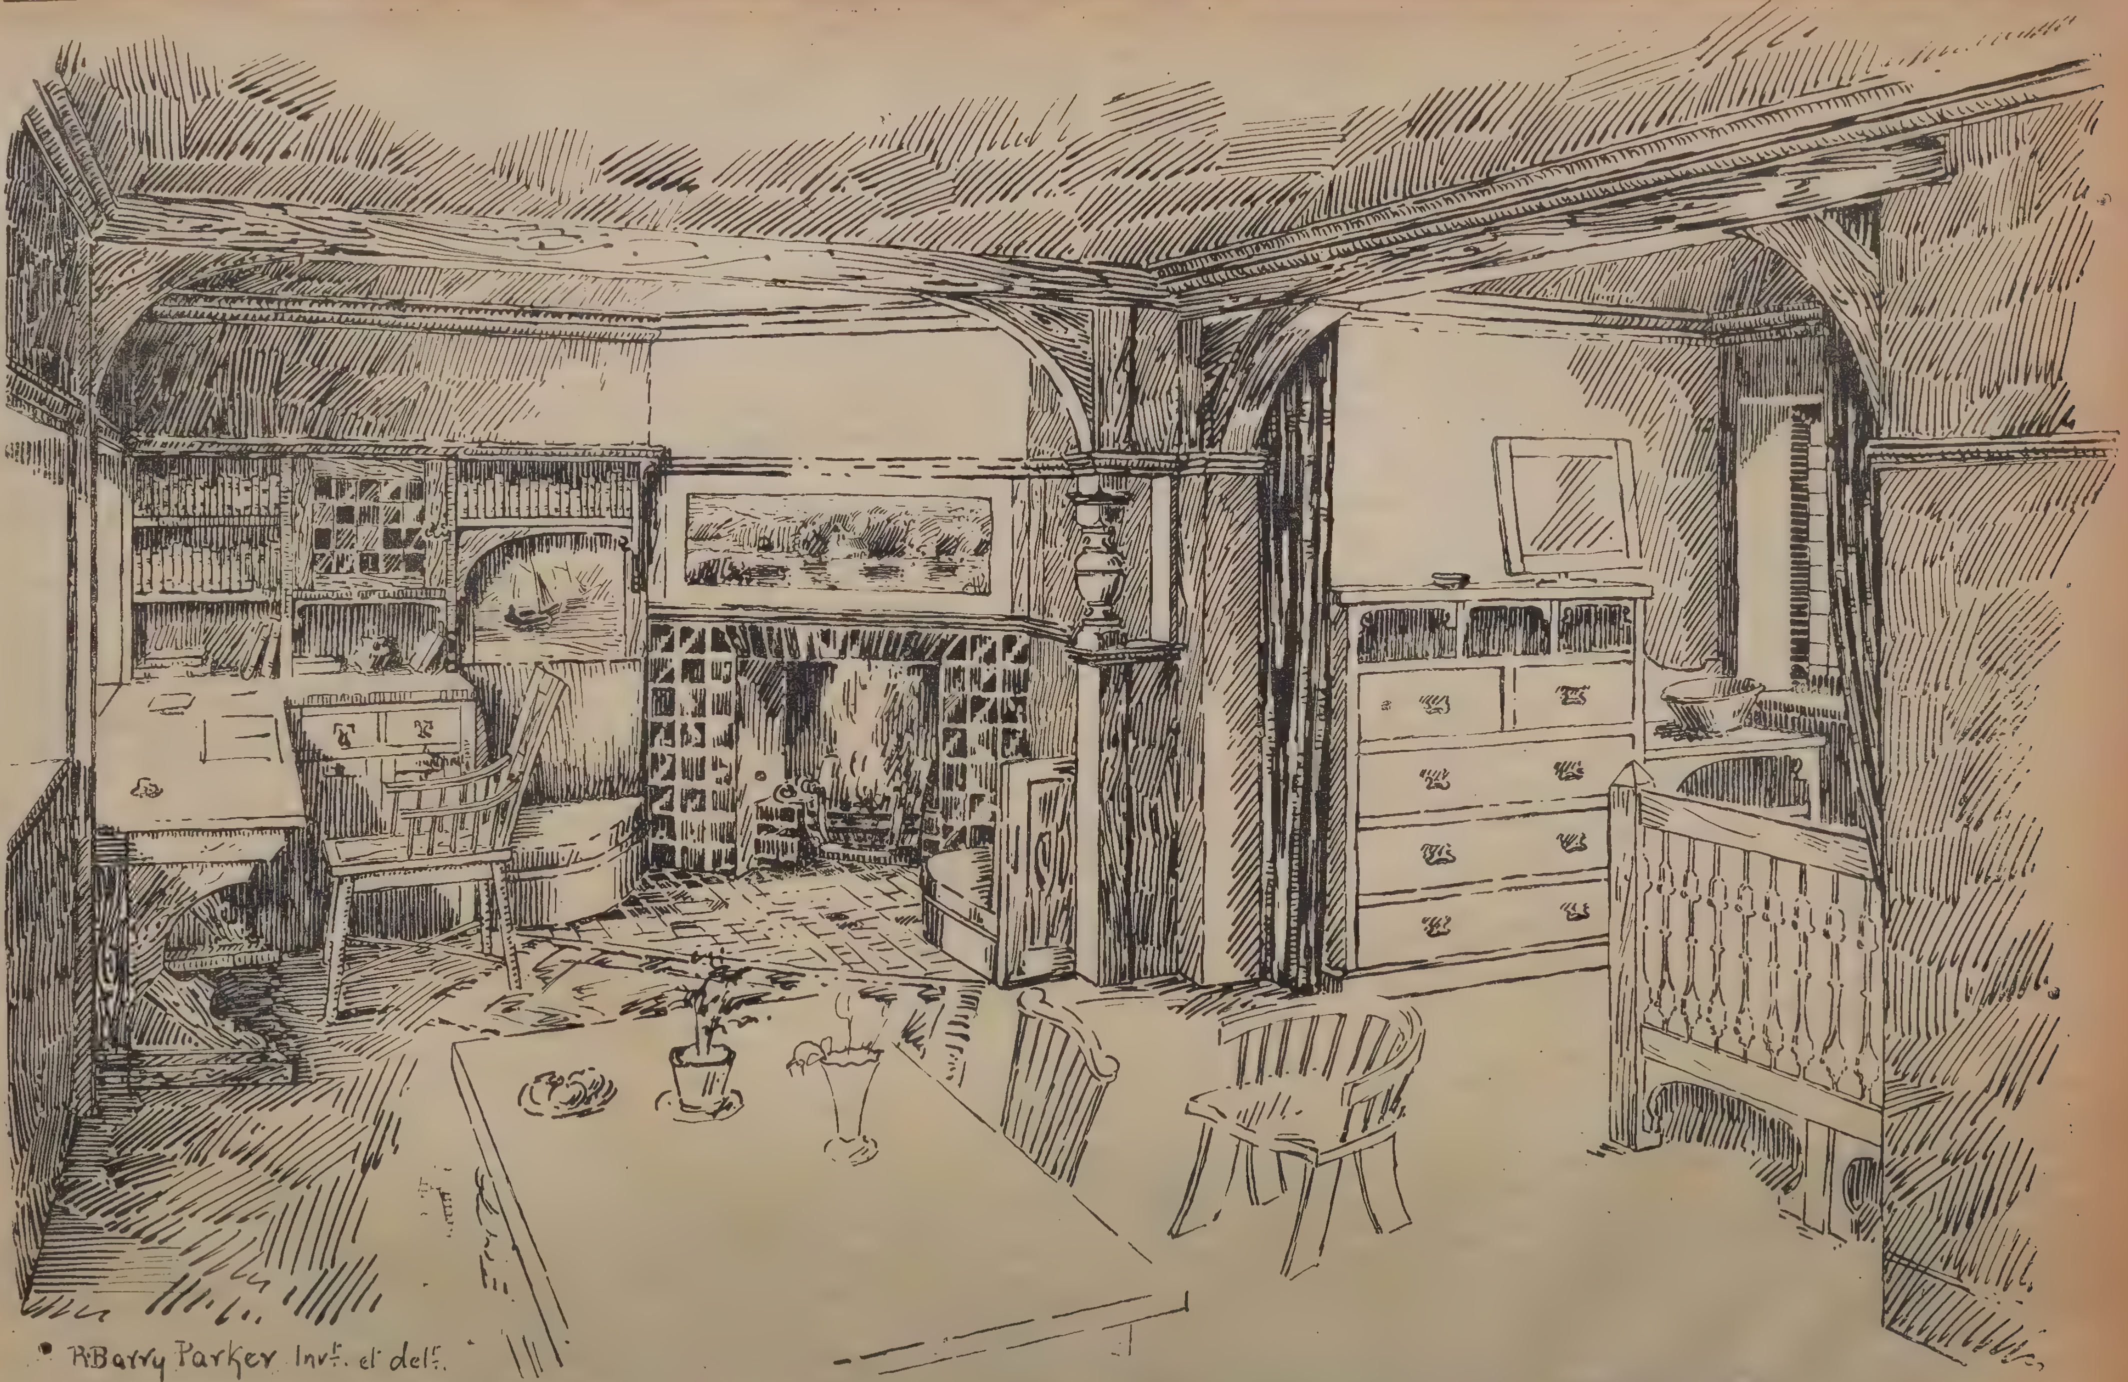
The advantages attaching to rooms furnished in this way, largely by means of fixtures, the accompanying sketches would do something to show. There is a unity, completeness, comfort, and repose about such which can never be got in rooms in which the furniture is not designed for its position and looking at home, but is just temporarily stuck where it happens to stand, with a look of being on the alert and ready to move at a moment's notice. The attempt to reduce everything to a form which can be produced by the thousand, and which will do to go anywhere, has knocked all the life and spirit out of design and handicraft. A thing which is right anywhere is right nowhere.

The influence of our present system of reducing everything to a level which may be produced by machinery—creating as it is doing, in place of the old craftsman, a class of men who are themselves only machines—strikes us afresh and with renewed regret every day; but the effect of this system upon ourselves, in the absence of that influence which the old artist-craftsman had upon us, through his work largely, passes unnoted by us.

Ready-made clothes fit better than ready-made furniture. The very essence and life of design is the finding the form in which the special aim, uses, and requirements of the thing to be designed can, with the maximum of beauty and convenience, adapt themselves to the special conditions and circumstances under which they are to exist; and perhaps the most fruitful source of charm in the design and form of anything is in the grace with which it adapts itself to its conditions, uses, position, and purposes.

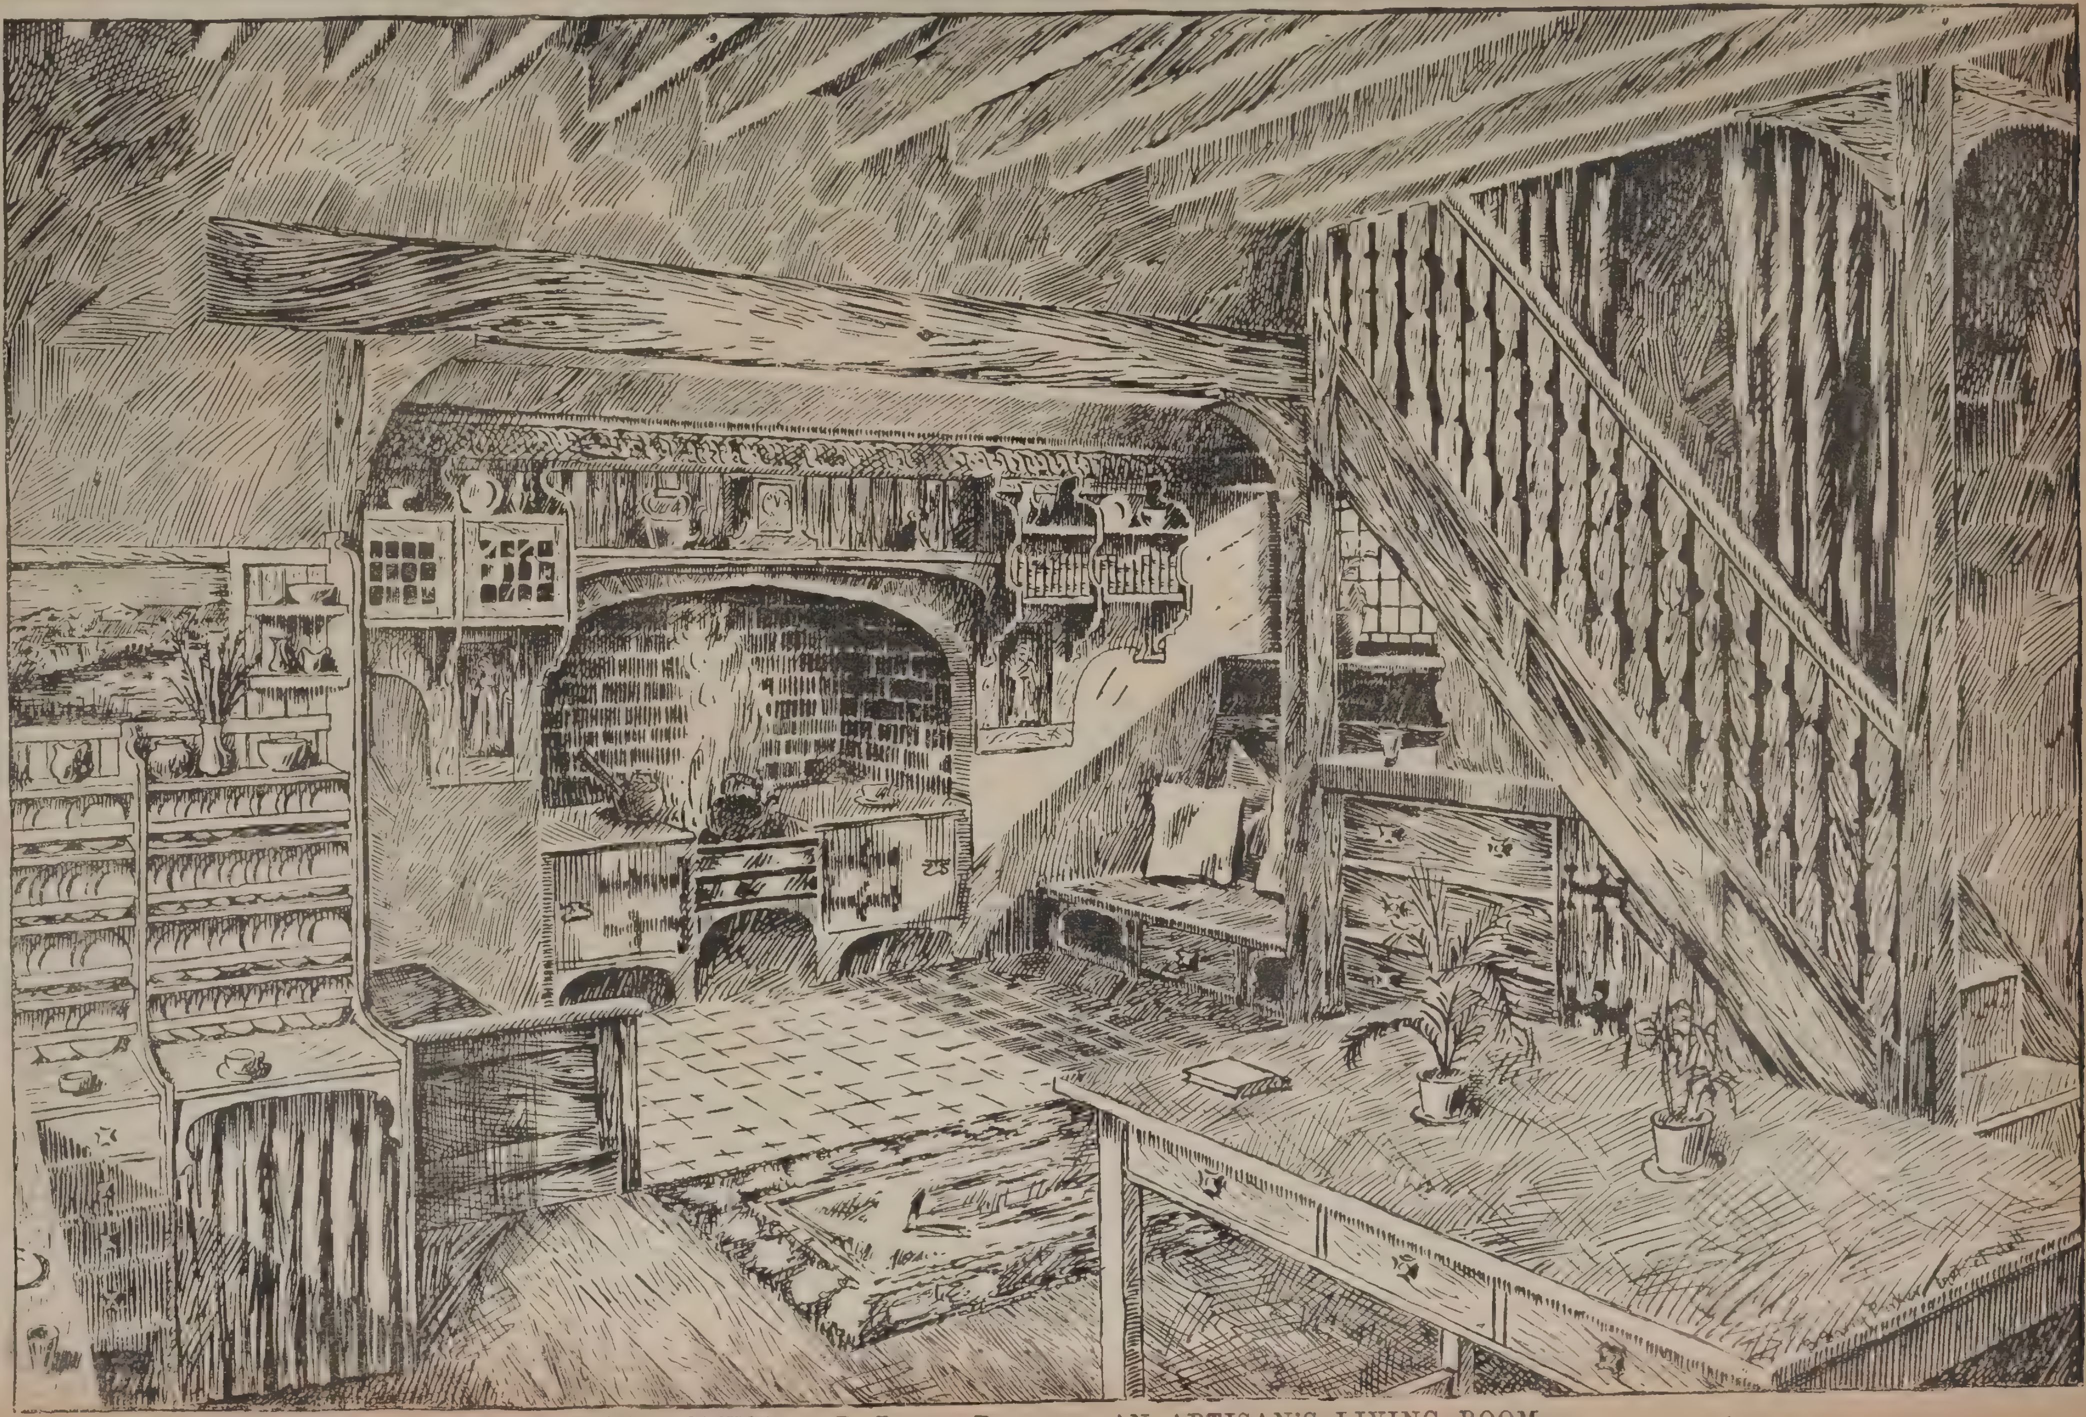
How many of the beautiful features of the work of past ages, which we now arbitrarily reproduce and copy, arose out of the skilful and graceful way in which some old artist-craftsman, or chief mason got over a difficulty; if, instead of copying these features when and where the cause for them does not exist, we would rather emulate the spirit in which they were produced, there would be more hope of seeing life and vigour in our architecture and design again.

It is well known that the creations, not only of nature but of man, in assuming the form best adapted to the discharge of their uses and functions under the conditions peculiar to them, also assume the most graceful form possible to them; and in the main, in the degree in which a thing adapts itself to its uses and environments, the more graceful will it be in shape. The best illustration of this is, of course, to be found in the forms of men and animals: but in the works of man the same thing holds good. The form of a boat was not determined by any abstract idea of beauty, but was chosen because it was best adapted to the functions of a boat—offered the least resistance to water in passing through it, and so on. And I observe the more fully it recognises and acknowledges in its form the nature and limitations of the conditions under which it is to exist, the more beautiful it becomes.



R. Barry Parker Invt. et delt.

"OUR HOMES," by R. Barry Parker.—A BED-SITTING ROOM.



"OUR HOMES," by R. Barry Parker.—AN ARTISAN'S LIVING ROOM.

"Beauty must come back to the useful arts." The only true method of making a room beautiful is to make all the necessary things in it also beautiful. So much is this true, that it becomes almost impossible to design a really beautiful room that is to have no useful work done in it, and natural life lived in it, and therefore has no useful and necessary things in it. This is one great advantage the farmhouse kitchen has (in common with all other workrooms) over the drawing-room. An architect called in to design a room in which nothing more earnest is to be done than to gossip over afternoon tea, has a hopeless task, and can never achieve a satisfactory result; for a room must always derive its dignity or meanness from, and reflect somewhat, the character and kind of occupation carried on in it. For instance, the studio, the smithy, the study of the man of letters, the workshop of a carpenter, the farmhouse kitchen, each in its position and degree, derives a dignity, interest, and individual and characteristic beauty from the work done in it. And the things in the room will bear some relation to that work, and will be the furniture and surroundings natural to it—as the easels and canvases in the studio, and the bright pans and pots in the kitchen.

But what useful occupation could be carried on in most drawing-rooms and in many of the other rooms spoken of here? About the only occupation of any kind which could be carried on in them is dusting, and this is attended with danger, for in most of these rooms one cannot move without fear of damaging something. And even this dusting cannot be regarded as a useful occupation, for how useless are the things on which it is expended, and how very few things of which the room is so full can make any claim to be allowed to exist from real intrinsic beauty! Do they really add anything to the lives of anybody?

But in a workroom all things have a place by reason of their usefulness, which gives a sense of repose and fitness entirely wanting in a room in which a place *had* to be *found* for everything.

The number of those who are tired of sacrificing themselves to their surroundings is daily increasing. These are tired of the life spent in anxiety, incessant toil and worry, that they may have one or more rooms they never go into, and may be surrounded by all these unnecessary and valueless things incapable of giving them any vestige of real pleasure. These are anxious to find houses suited to their genuine wants; houses in which they can live a truer, healthier, more natural life than is possible to them now; houses in which the work will be reduced to a minimum, and the beauty increased to a maximum, by the only true method of making all the useful and necessary things beautiful; not by the false method of keeping all useful and necessary things out of sight, trying to conceal their purpose, or to appear unconscious of their existence.

We want rooms where we have space to carry on the business of life freely and with pleasure, with furniture made for use, not for sale only, as most is now; rooms where a drop of water spilled is not fatal; where the life of a child is not made a burden to it by unnecessary restraint, and those who are there with it have not to give up all their time to anxiously watching that it "does no harm" and "touches nothing." Plain, simple, and ungarnished, if necessary, but honest.

Let us, wherever possible, have such ornament as we do have really beautiful and wrought by hand — carving, wrought metal, embroidery, painting—something which it has given pleasure to the producer to create, and which gives evidence of this in every line; which is, and always will be, the only possible work of art.

Let us call in one of the numberless artists who are almost starving throughout the land. Let him leave his easel-pictures, and paint on our walls, panels, and over the chimney-corner landscapes and scenes which shall bring light and life into the room; which shall speak of nature, purity, and truth, and shall become part of the room, of the walls on which they are painted, and of the lives of us who live beside them; paintings which our children shall grow up to love, and always connect with scenes of home with that vividness of a memory from childhood which no time can efface.

Then, if necessary, let the rest of the walls go untouched in all the rich variety of colour and tone, of light and shade of the naked brickwork. Let the floor go uncarpeted, and the wood unpainted, that we may have time to think, and money with which to educate our children to think also.

Let us have rooms which, once decorated, are always decorated; rooms fit to be homes in all the fullest poetry of the name; in which no artificiality need momentarily force us to feel shame for things of which we know we need feel no shame; rooms which can form backgrounds, fitting and dignified, at the time and in our memories, for all those little scenes, those acts of kindness and small duties, as well as the scenes of deep emotion and trial, which make up the drama of our lives at home.

EXHIBITION OF NATIONAL COMPETITION DRAWINGS, KENSINGTON.

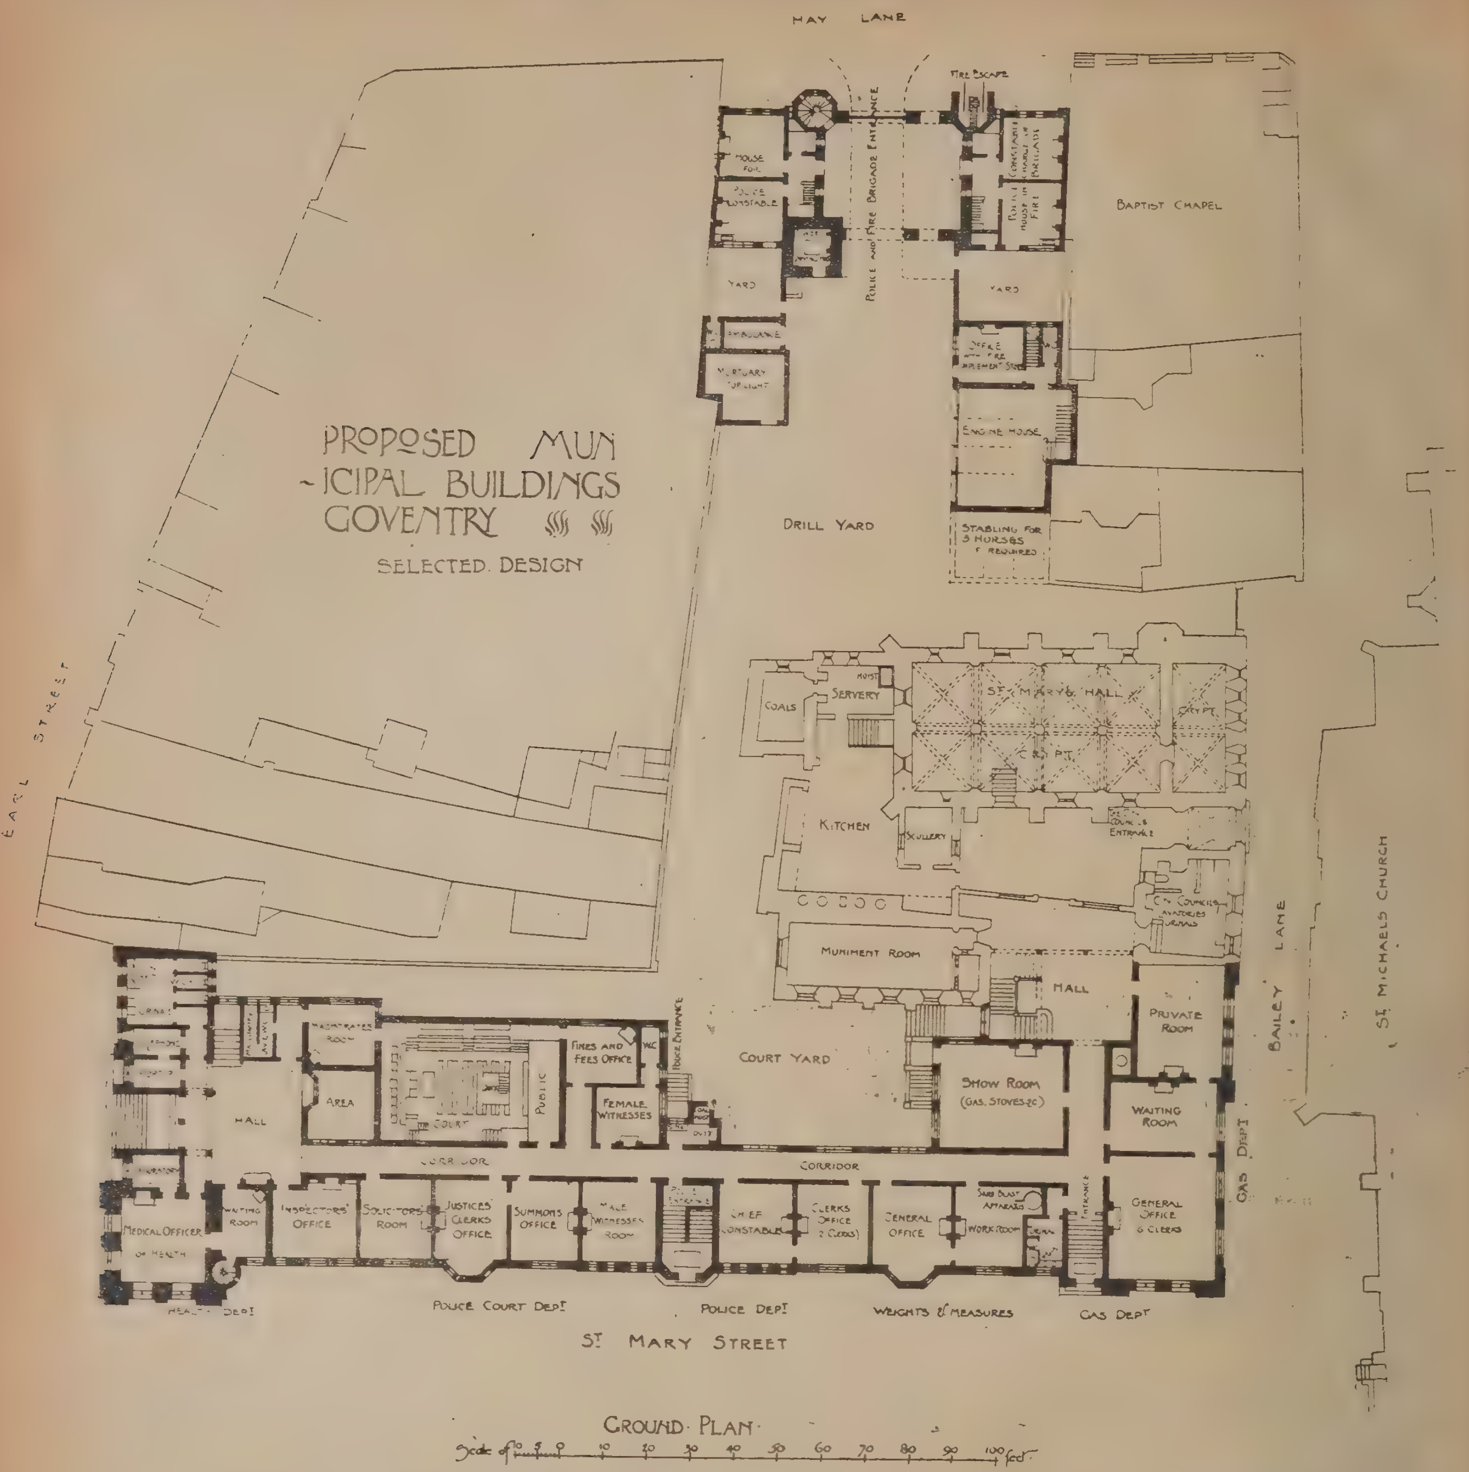
YESTERDAY the annual exhibition of students' works was opened in the newly-built galleries in Exhibition-road, near the Machinery Section buildings, and the collection, numbering some 874 models and drawings, as a whole, seems equal to the average standard, though the drawings in the Architectural section and in the Applied Arts department, more particularly those associated with building work, scarcely present any one example of more than ordinary merit. The examiners of Architectural Design, Messrs. Geo. Aitchison, A.R.A., T. G. Jackson, A.R.A., and J. J. Stevenson, have, we suppose, made the best choice in their power. We may at any rate presume that in some cases the prizes they award would not have been given had better work been presented for competition. Their report repeats the ever-timely warning to students, "that deceptive construction, such as imitation of half-timber work by veneers of thin boards and plaster, is inartistic and inexcusable, and has in cases prevented awards being made. Another instance of bad design is the dividing of the upper half of a window by sash-bars into small panes, while there are none in the lower." How far this latter point may reasonably be insisted on is, however, a matter of opinion, and when we notice in some of the designs chosen for prizes, certain discrepancies of a far more serious character, it becomes difficult to understand how the experts who adjudicated in this instance permitted so unimportant a consideration to weigh sufficiently with them to exclude other designs from the contest entirely. Mr. Jackson wishes to add, with good reason, that, in his opinion, to "trick up geometrical elevations into pictures is not only useless, but mischievous, encouraging students to think in elevation rather than in perspective, and the public to believe that an elevation gives a true idea of a design. The art of elaborately shading geometrical drawings has no practical value. No architect ever makes such drawings in his practice, and there is no demand for assistants who can do them." This edict, so tersely expressed, scarcely accords with the teachings so long the leading characteristic of the Royal Academy Schools, and while, no doubt, Mr. Jackson correctly describes the practice of the profession in England, his remark is certainly at variance with the custom of French and Continental architects, whose speciality in this respect has always found a warm advocate in the architectural master at Burlington House, Mr. Phené Spiers.

The leading architectural prize work at South Kensington is to some extent second-hand, seeing that Mr. Charles Quennell, of Lambeth, obtains a Gold Medal for a design that was submitted under the motto "Lion's Head" in competition for the Soane Medallion at the R.I.B.A. last year. The subject is an art gallery, and its chief feature is a dome, which, in reality, would look very depressed in outline. The design is marked by flaming ornament, which is over-large in scale, but at least is not finnicking, in its proportions, like some big modern buildings' enrichments unquestionably are. Another Gold Medal is awarded to Mr. A. H. Hodge, of Glasgow, for his design for a similar art gallery, which he has conceived, with no small degree of imagination, in a Northern Italian style, florid in colour decoration and mosaic work, but impossible for practical utility, and very indifferent in plan. The elaboration of the pavements and other ornamental work has occasioned vast labour to be expended upon a design which fails in the elements of appropriate character. Mr. Geo. A. Paterson obtains a Silver Medal for a public school chapel, which he has designed in a very thin kind of Gothic, and drawn in perspective in exceptionally coarse ink lines, with wild clouds sweeping like conventional ribbons from one side of the sky to the other, robbing the building of all repose and scale. The pulpit is placed in front of the altar, and the seating is too crowded to make a good plan, though the building is drawn after the manner of the fashionable cult in architectural matters. Mr. T. A. Williams takes a silver medal for a memorial church design which recalls something we have seen in Wales by a Chester architect, possibly at Barmouth. The tower over the choir is sturdy and good, with details generally of Late 14th-century work. One of the best things in the gallery is a Silver Medal design for a Riverside Warehouse, by Mr. E. F. Reynolds, of Birmingham, treated with reserve, and handled with suitable simplicity in brick and stone; but the relieving arches over the stone lintels are omitted. The perspective sketch is not very well managed. One of the Tite Prize competition designs from Conduit-street, for an Exchange, has secured a Bronze Medal. Mr. J. G. Gillespie, of Glasgow, is the author, and Mr. H. P. Sharpe, from the same city, has taken another National Medal for an ungainly Village Church with two towers, and badly-proportioned side windows, of the same width as the recess for the organ. Surely Mr. Jackson cannot admire such a design as this? It is described in the report as a College Chapel, and the design is spoken of as "unequal in parts." It looks really all of a piece. Mr. G. H. Lenfestey obtains a Gold Medal for some pencil sketches of French staircases which do not seem quite so charmingly drawn as the report indicates, and Mr. R. I. Beale, of Maidstone, is awarded a Bronze Medal for some careful, and in a way spirited, sketches, of the pulpit at Cliffe, with its hour-glass stand and other Jacobean details. Mr. Chas. B. Howdill, of Leeds, taking a less familiar subject for measurement, sends a detail of the retro-choir screen from St. Bavon's Church, Ghent, a work in masonry, with brass balusters of admirable proportion. The screen is in marbles, and Renaissance in style. The statue at the top has not been properly delineated. A Bronze Medal is given for this, and others are dispensed to Messrs. Gladwell, Vinall, and Thorogood for unsympathetic outlines of the cast in the Museum, taken from the stalls of St. Denis, Paris. There is no "tricking" up in these elevations, to use the examiner's phrase, and one can but wish that some little spirit of "go" had been infused into their delineations. Mr. Mavart sends some poor drawings from Glasgow Cathedral which take a Medal, and Mr. P. W. Meredith's studies from Wells Cathedral Chapter House hardly merit the honour. The exterior sketch is a libel on the building. Another poor set from Bolton Abbey, by Mr. Whipp, of Rochdale, receives also a Medal unaccountably, thereby making the prize somewhat too cheap. Broughton Church, Oxon, supplies Mr. Harry Rogers, of Banbury, with a subject for his geometrical diagrams, obtaining a Book Prize, and Mr. J. F. Walker takes a Silver Medal deservedly for a set of drawings from the queer, but clever, Classic church of St. Mary, Banbury, which of late years has been skilfully decorated. The General News Rooms, Leicester, is another Classic building, but much more severe in style, with the Ionic order to the portico. Mr. J. Clarke sends some big details of it, and is given a Medal. The figures are very badly shown, and reflect upon the justice of the award. The organ in St. Michael's Chapel, Brownsover, formerly belonged to St. John's College, Cambridge, and is a handsome instrument, with bold and picturesque exterior. Mr. A. E. Martin, of Rugby, has but indifferently drawn it in outline, and his sketch is unfinished. We note more care expended on the detail sheets, and so he wins a Bronze Medal. A like prize is given to Mr. Ch. F. Dawson, of Shipley, for a firm and crisp drawing of an inlaid oak chimneypiece, dated 1610, from Riddlesden Hall. The darker parts of the pattern are tinted neatly in grey. The drawings of the George Inn at Glastonbury, by Mr. A. E. McKewan, seem painstaking enough; but, having ourselves carefully sketched the same building, we doubt the correct proportions of the façade, as shown on this sheet in perspective. It obtains a Book Prize, which the author well deserves for his industry. One of the most refined pieces of work shown in this connection is a statuary marble chimneypiece from Leinster House, Dublin, with figures by Nollekens, and here drawn full size, with grace and feeling, by Mr. W. L. Whelan, who is given a Silver Medal for his work. The outline is spiritless, but the figure in monochrome is very capital. Temple Bar, Theobalds, Essex, and the Marino Casino, by Sir Wm. Chambers, Dublin, are other subjects in the same style. Gothic work is not strong in the exhibition; but we notice some drawings of the Countess of Salisbury's chapel at Christchurch, Hants, by Mr. H. C. Wallis, of Ryde, whose pretty sketch of the exterior is attractive, and we note his plan of the Priory Church complete, and think he merits the Medal awarded, though we cannot admire the cold-grey interior of the chantry. The Fox Chantry at Winchester, by Mr. F. C. Nash, is fully delineated, and takes a Silver Medal; but we scarcely think the original obtains justice, for the drawings are not first rate. The N.W. chapel at St. Michael's, Coventry, is shown by a pencil drawing by Mr. F. H. Brown, not badly executed, and a Bronze Medal is taken by Mr. A. McKewan for a village school design. The Silver Medal design for a sideboard in oak, by Mr. H. Davis Richter, of Bath, is one of the most elegant and original proposals in the furniture way which we have seen lately. The curved top is finished with a chastely proportioned cornice, and the Late Renaissance has clearly been carefully observed. Full-size cartoons display the exact contours. Mr. F. W. C. Gregory, of Nottingham, takes a Bronze Medal for a good cabinet, which recalls the Vicarage Gothic a trifle too much, and the design is wanting rather in repose, but deserves recognition certainly. We much admire the cast bronze lock by Mr. Leon V. Solon, with its two gladiators holding shields, modelled in low relief, well adapted to the metal and its position. Mr. G. A. Paterson, already named, sends a good design for a drawing-room chimneypiece in stone, broadly treated, but the elevation fails rather for lack of concentration, being so "all over" in effect. A Silver Medal is well given to Miss Mary I. Newill, of Birmingham, for her reredos cartoons (and central figure worked in wools) of three angels. The face in the finished work is dirty in tint, but the reds and greens are harmonious and subdued. The wings in red seem hardly a success in drawing. St. Christopher is the subject of another Silver Medal Cartoon, by Miss Agnes Manly. The figure drawing is capital, and the drapery is artistically shown; but the general result of the cartoon has an over-wrought effect.

A YEAR'S WORK OF THE LONDON COUNTY COUNCIL.

IN his first annual address on the work of the London County Council, Sir Arthur Arnold expressed surprise that the control of the water supply, of artificial lighting, and of public markets were thought by some people to involve too great a strain on the energies of the Council. He professed full confidence that they could undertake and digest whatever work might be found proper for the central authority of London. He then proceeded to remark in detail on the work of the principal committees. With regard to the Asylums Committee, Sir Arthur mentioned that the existing asylums provide for 10,400 patients, and that the Council had approved the erection of a new asylum at Bexley for 2,000 patients, the cost of which, exclusive of site and equipment, will be £375,000. He congratulated the Bridges Committee on having surmounted the main difficulties in the construction of the Blackwall Tunnel, the cast-iron-lined portions of the tunnel being already far past the centre of the river bed. The number of men working in compressed air is about 120, and there have been only five cases of serious suffering from the peculiar nature of the work. The opening of the tunnel will probably take place in 1897. The next great work of this committee, which has been sanctioned by Parliament and has received the Royal assent, will be the new Vauxhall Bridge, 80ft. wide, with gradients of 1 in 40, to be constructed at a cost of £380,000, including £30,000 for a temporary bridge. The building Act Committee had, he thought, done wisely to retain as their chairman that member of the Council who, more than any other, laboured for the passing of the Building Act of 1894. Their thanks were due to Dr. Longstaff for the assiduity and ability he displayed in the promotion of that statute by which the Council have secured consolidation of the law regulating streets and buildings in London. Among other valuable functions, the Corporate Property Committee have entered upon the preparation of a ground-plan of London, and 206 estates, representing about 30 square miles, have been delineated. He hoped, however, that the Council would not proceed in minutest detail to examine the tenure of all land in London, because the difficuty and cost of that operation would, in his judgment, very far outweigh its value, which, with constant changes of ownership, would not be permanent. The Fire Brigade Committee are proceeding with the provision for additional protection from fire. The staff already numbers 920. The annual cost of this department, which is now £210,315, must increase. By the substitution of "H." for "F.P." in all parts of the county, the public can judge how largely the Council have caused fire-hydrants to be substituted for the obsolete fire-plugs. In the report of the Highways Committee will be found statements of the policy and proceedings of the Council with regard to electric lighting, tramways, and the telephone service. In two places where gates have been removed under the Acts of 1890-93 it has been found that an average of 2,200 and 1,131 vehicles now pass daily. The committee find that out of more than 200 railway stations in London not fewer than 177 need improved accommodation, and have made suggestions, which they are at present powerless to enforce upon the respective railway companies. The Improvements Committee are controlled in their larger schemes by the financial policy of the Council. But the committee were, he thought, entitled to congratulation upon the position of the Wellington-street improvements in connection with the Duchy of Lancaster, of the Tower-bridge approach on the south side, and upon the instruction they have received from the Council to prepare a scheme for the formation of a new street from Holborn to the Strand, subject to the conditions as to betterment imposed in the case of the Tower-bridge approach.

The Chairman dwelt at considerable length on the work of the Main Drainage Committee. When the Council came into existence the river was more foul than at any time since the construction of the main drainage system nearly forty years ago. The pumping machinery at Abbey Mills and elsewhere was obsolete and dilapidated, and the low-level sewer was overcharged as far eastward as Somerset House. By compounding the engines at Abbey Mills and by repair of the pumps they have accelerated the self-cleansing flow of the main drains, the low-level sewer is not over-full, and has now always a steady flow in dry weather. The committee have cleansed the river by carrying away to sea 2,000,000 tons of sludge per annum, in six vessels which have cost about £147,000, and the effluent passing into the river after the removal of the sludge is clearer that the river water, and can be made innocuous by passing it through filters of coke breeze. The sludge vessels made over 2,000 passages last year at a total cost of about £40,000, or of £19 3s. 2d. per trip. There is no deposit on the sand in the Barrow Deep where the sludge is emptied. £150,000 a year is spent in connection with Barking and Crossness in thus dealing with the sewage. The most interesting experiments been in the filtration of sewage and in examining the atmosphere of sewers. A filter of one acre has been constructed, the material consisting of 3ft. of coke breeze covered for retaining purposes with 3in. of gravel. The quantity of effluent running through this filter is about 1,000,000 gallons daily, and the clarified result passing into the river has so improved that fish live for many weeks in it. If it were desired, the whole Metropolitan sewage could be treated in this way upon about 180 acres of land, with perfect freedom from noxious smells in the operation, and then the effluent would be much less foul than the ordinary waters of the river. The cost of making this filter, exclusive of land, has been about £2,000 for the acre. The Council lately engaged Mr. Parry Laws to make experiments in sewer air, and his investigations show most clearly that there is no resemblance whatever between micro-organisms of sewage and those of sewer air. He found that not any of the organisms which predominate in sewage existed in sewer air, and the experiments demonstrate very strongly that the possibility of the existence of the typhoid fever bacillus in the air of sewers is indefinitely remote. The chairman next dealt with the probable limit to the purity of the river. The drainage system is, he explained, so constructed that $\frac{1}{4}$in. of rain per day may possibly pass away by the sewers into the precipitation tanks at Barking and Crossness; but if $\frac{1}{8}$in. falls in a single hour upon ground already saturated, then all the main sewers begin to pour their overflow directly into the river. This overflow occurs perhaps 20 times in a year, and is not to a certain extent preventable. It is evident, therefore, that a perfect cleansing of the river is impracticable; but the question will soon arise whether the main sewers have reasonably adequate capacity for the increasing area and population. In order to make the main drainage system capable of discharging, without overflow into the river, $\frac{1}{3}$in. of rainfall in 24 hours, a further expenditure of about $2\frac{1}{4}$ millions will be needed for the construction of new main sewers from Paddington on the north side and from Balham and Streatham on the south side, and, indeed, if the capacity of the main sewers are to be made proportionate in efficiency to those of other cities, this work must be undertaken forthwith. The acreage, under the control of the Parks and Open Spaces Committee, has risen from 2,656 to 3,684, but the cost of maintenance has grown in much larger proportion from £52,751 to £100,932. The area of Royal parks within the county is 1,438 acres, and the expenditure £56,058, so that if the expenditure of the committee was upon the same proportion, it would amount to £130,000 a year, and it may be added that our open spaces are small and scattered, and therefore more costly than the Royal parks in regard to management. The Public Health and Housing Committee labour under the weight of the vast problem which connects them with the housing of the working classes of the Metropolis. The committee have had to provide housing in some cases upon sites which no private enterprise would look at, and the result has not, Sir Arthur admitted, been wholly satisfactory from the financial point of view. On a total estimated capital cost of £146,785 there is a probability of an annual charge of £669, or say $\frac{1}{2}$ per cent., falling on the rates for the next 54 years. It must not, however, be assumed that the same proportion of loss would result from every scheme. But progress in this work must be cautiously scrutinised. The Council have lately resolved that before deciding to acquire or appropriate lands for the purposes of Part III. of the Act, the Finance Committee shall report on the estimated financial effect of the scheme, including the erection of dwellings on such lands. The Stores Committee have continued the plan of limiting contracts to one year only, and, in order to afford facilities for manufacturers of special goods to submit prices, the tenders for each item in the schedules are considered separately. The Water Committee have done much to prepare the basis for the Bills recently before Parliament, and are now inquiring as to suitable gathering grounds in Wales for the future supply of London, in pursuance of a recent resolution of the Council. The Water Committee have also been much concerned with the results of the severe frost, which demonstrated the insufficient depth of many of the companies' mains and service-pipes. It is noticeable that in capitals where there is much greater severity of frost the freezing of water-mains is uncommon, because of the greater and uniform depth at which they are laid. He congratulated the Works Committee upon having overcome many of the difficulties inseparable from the commencement of an undertaking so novel and in circumstances of great emergency and exigency, and not less upon the fact that the character of the work they have executed has been acceptable and generally excellent. He should be surprised and disappointed if the excess of cost which has occurred in so many cases should be continued. In his opinion the establishment of the Works Committee was a necessity. Trade-union rate of wages, in practice obtained by the co-operation of employers and employed, is the only rate of payment which can meet the just claims of the whole body of electors, and the adoption of this rule undoubtedly led to so much difficulty with the contractors that the institution of the Works Committee was the unavoidable result. It has never been suggested that the Council should cease to deal with contractors, and, as a matter of fact, they have never ceased from such dealings. But he was sure that the existence of a Works Committee exercises a salutary influence, and in giving or withholding work from that committee, the members must not forget that they will soon have a large capital invested in shops and stores, the charge for which must be distributed throughout their operations. In conclusion, Sir Arthur referred with approval to the work thus far accomplished by the Technical Education Board; but suggested that the title ought to be changed from "board" to "committee."



COVENTRY MUNICIPAL BUILDINGS COMPETITION.

THE FIRST PREMIATED DESIGNS.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

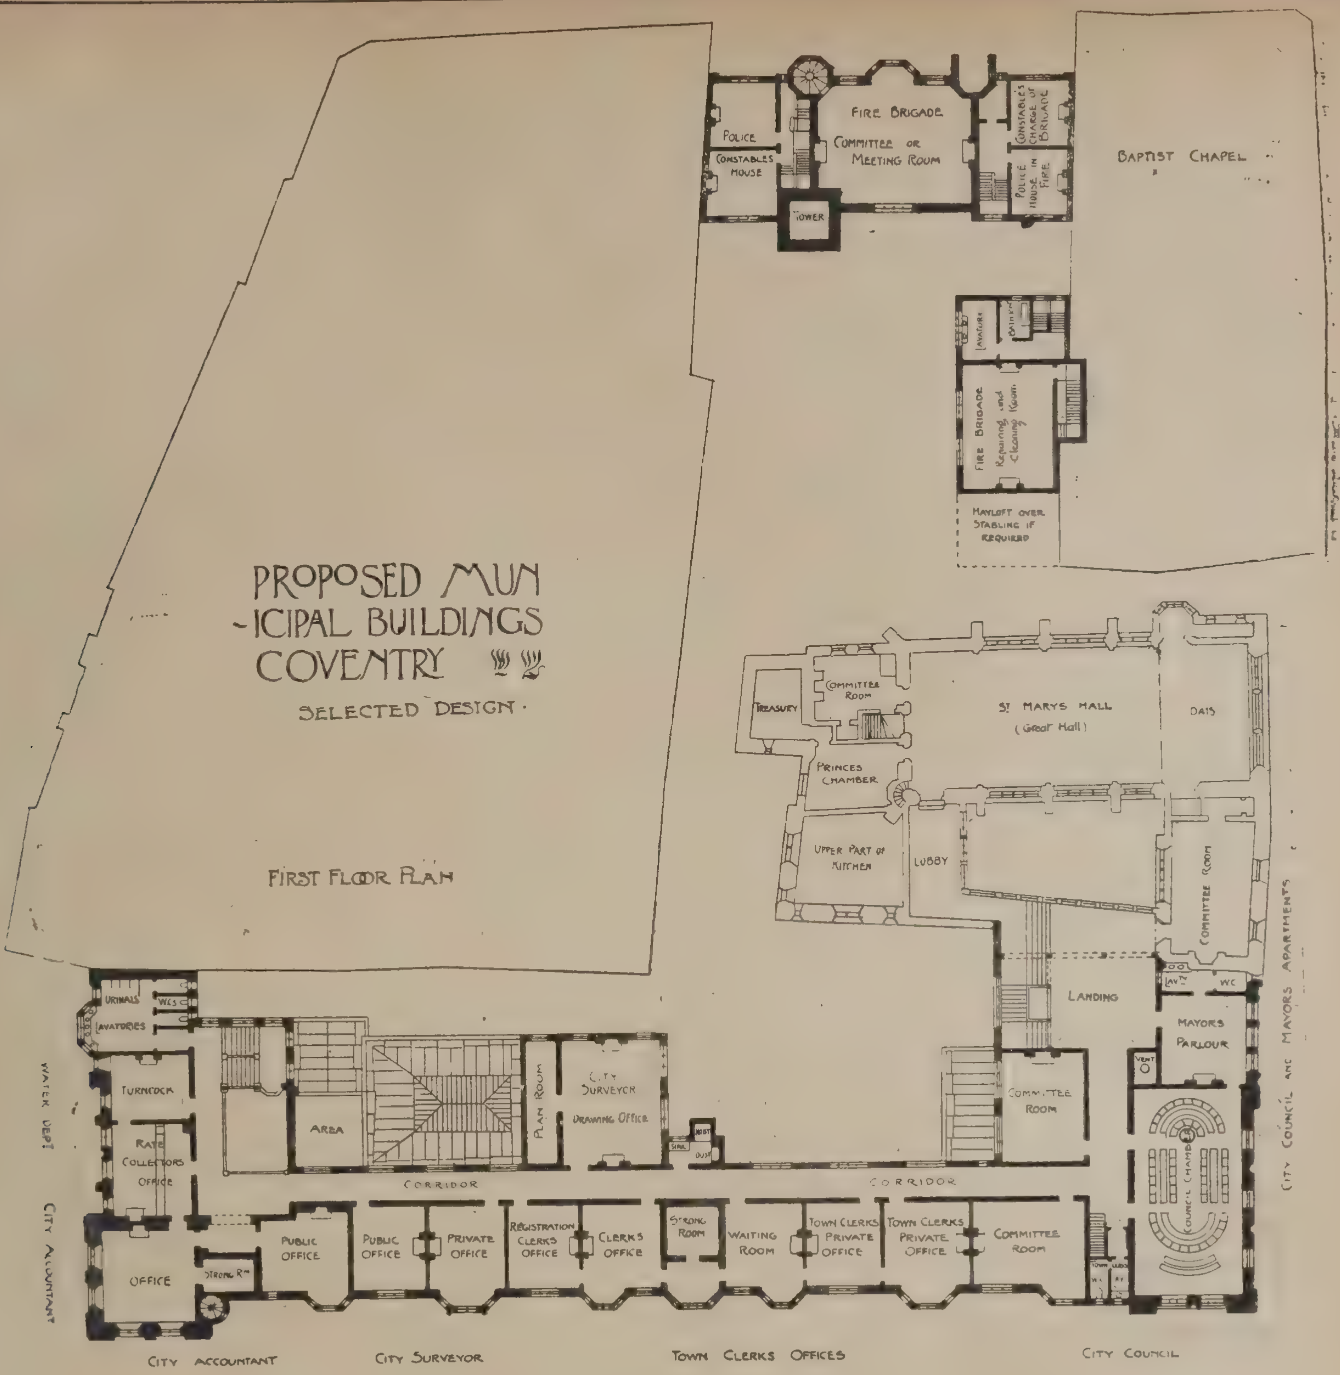
THE competition for these important buildings was recently decided by Mr. C. Barry (the assessor) in favour of the drawings submitted under motto "Leofric the Saxon," the authors being Mr. Harry Quick, of Coventry, in conjunction with Messrs. Brewill, Baily, and C. E. Mallows, of Nottingham and Bedford. The drawings published herewith sufficiently explain themselves; the leading characteristics of the scheme generally are studied simplicity of plan, economy of space on an unusually cramped site (where ancient lights are an important consideration), and adaptability of the new work in plan and elevation to the fine old hall of St. Mary, which has been incorporated with the new buildings so as to be used *en suite* with the council chamber and mayor's parlour, which are placed for that purpose on the Bailey-lane, or northern, front, facing the south side of St. Michael's Church. That this might be made the quietest portion of the site was another excellent reason which determined the position of the council chamber, and also led to the placing of the police-court to the position it occupies, at the back of St. Mary's-street front, and near to the principal entrance on the ground floor. The entrance to the council chamber is through the 15th-century groined gateway in Bailey-lane, which has been used for that purpose for ages, and which it was thought best to retain in order not to disturb old traditions. The continuity of the plan is kept, and suitable provision for the various municipal offices best provided for in the main block by placing the Fire Brigade station and drill-yard, &c., to the Hay-lane frontage, which, owing to that street being rather narrow, has been set back some feet in consequence. Externally, the type of Late Gothic (of which St. Mary's Hall is such a beautiful example) has been adopted, and an earnest attempt has been made on the Bailey-lane front and elsewhere to properly carry out the lines of the old work, so that the new shall be in artistic sympathy, not only with St. Mary's Hall itself, but with the surrounding architecture generally.

* * *

The Duchess of Devonshire laid on Monday the foundation-stone of a new infant-school in connection with St. Mary's, Ulverston.

PROFESSOR BOYD DAWKINS ON THE AGES OF MAN.

PROFESSOR BOYD DAWKINS opened, on the 17th inst., the Antiquarian Section of the Royal Archæological Institute, the members of which have been holding their annual meeting at Scarborough. He said that the study of antiquities, so long a mere *dilettante* study, had now become an exact science, and the question of the antiquity of man, so eagerly discussed in the "sixties," had now passed into the region of well-ascertained fact. The Palæogean implements associated with the remains of the extinct mammalia, such as the mammoth and the woolly rhinoceros in the caves and river deposits, proved that man found his way into Britain when our land formed part of the Continent, and when the winters were sufficiently severe to encourage the migration of reindeer and other Arctic animals, while the summers were sufficiently warm to allow of the hippopotamus wandering as far north as Kirkdale and Leeds. The relation of Palæolithic man to the glacial phase of the Plesiosaurus period was clearly shown by the distribution of his implements in Yorkshire and in the South of England. The Palæolithic implements in the caves in the districts covered more or less



by the glacial drift showed that man was living in Yorkshire in pre-Glacial times. A Palæolithic man was about 5ft. 3in. high. The skulls and bones of Palæolithic man which were beyond dispute were too fragmentary to allow of their being identified with any existing race. They were, however, sufficient to prove that when he first appeared in Northern Europe he was a man, and not a missing link. The Garden of Eden, in which he was evolved from a low ancestry, was to be looked for in some part of the world other than Europe, and up to the present time unknown. The higher antiquity of man had not as yet been established. The relation of the Neolithic to the Palæolithic age, keenly discussed during the last ten years, had not yet passed into the region of undisputed fact. For his part, he was unable to recognise a trace of continuity between them in this country, or in Europe, or in any other part of the world with which he was acquainted. To him, as a geologist, they were separated from each other by a profound change in geography, in climate, and in animal life in Western Europe. If, however, the Palæolithic and Neolithic inhabitants of the British Isles were separated by these great changes, which, from their experience, they might take to have been slowly brought about in untold ages, still more were they separated by their habits, manners, customs, mode of life, and general condition. The Palæolithic men were nomad hunters, ignorant of all arts except sewing, implement-making, and the use of fire. It was strange that, in the midst of this savage life, one section of the cavemen should have left behind figures of the animals on which they lived. The Neolithic men were not only hunters, but farmers and herdsmen. To them they owed the domestic horse, so dear to all true natives of Yorkshire. They were spinners and weavers, and miners of flint for the manufacture of implements, which they turned to use in the clearing away of the forest and the development of carpentry. They lived in fixed habitations; but in spite of this immeasurably higher culture, they were singularly devoid of the art of reproducing natural forms, which their Palæolithic predecessors carried to so high a pitch in England, France, and Switzerland. While there was no proof of the contact between the Palæolithic and Neolithic dwellers in Europe, all who believed in the descent of man from one stock must hold that in some quarter of the world the Palæolithic hunter gradually became educated into the Neolithic farmer. Professor Dawkins referred to the "Bronze Age," and said that the many skeletons which had been met with in almost every part of the British Isles proved that the use of bronze was introduced by the tall, broad-headed ancestors of the Irish Celts and the Gaels of Scotland. Dealing with the prehistoric archæology of the district of Scarborough, the speaker said it had yielded an abundant harvest to many explorers during the last ten years. The physical characters of the district were very remarkable. To the north and west lay the lofty Oolitic heather-covered moors of Cleveland, deeply cut into well-wooded ravines and valleys, leading southwards into the great alluvial plain of the Upper Derwent, which extended eastward almost as far as the line of cliffs between Scarborough and Speeton. To the south of this were the lofty and precipitous range of chalk wolds sweeping from Settrington eastward to Speeton, and gradually descending to the south-east along a line from Bridlington to Driffield and Beverley, and from Hessle to the marshes and ancient moors of Holderness. It was also divided by a central valley into two parts. It was in the higher grounds that they met with traces of man in this district, in the implements and weapons, in the ancient dwelling places and burial mounds, and last, though not least, in the series of earthworks which guarded the uplands from attacks. The axes and some other stone implements found in the surface soil of the district and in burial-mounds proved that it was inhabited in the Neolithic age. They were, however, few in number, and implied a sparse population, who interred their dead in a crouching posture. In the Bronze Age the population was very considerable, as was proved by the large number of tumuli, most of which contained stone implements known to have been used at that time from their association with bronze implements elsewhere. They burned their dead, as a rule, in that age, although the practice of interment was still carried on. Were it not for this they would have had no material for identifying the men of the Bronze Age with a living race. The Neolithic remains belonged to a small, long-head Iberic race of men—the oldest stock in Europe, to whom the living small, dark Yorkshire men and women owed not only their dark hair and eyes and long heads, but the taste for horseflesh which, as everyone knew, was one of the attributes of the dwellers in the county.

THE INTERNATIONAL HEALTH EXHIBITION, PARIS.

THE International Health Exposition, organised by the newly-formed Society of Sanitary Architects and Engineers, was opened on the 27th of last month at the Palais dés Arts Liberaux, in the Champ de Mars, and will remain open until the 15th of September next. This exhibition is enjoying an almost unexpected success; the various sections of exhibits are exceedingly well arranged, and there are a large number of very interesting novelties and apparatus pertaining to the service and practice of sanitation. A list of the sections and subdivisions of the exhibition has already been given in the BUILDING NEWS. The five chief sections consist of—sanitation of private and collective dwellings, town sanitation, sanitary science and health statistics; food, clothing, and physical exercise; industrial and professional sanitation. Before making a summary description of the exhibits, of which sketches of the most novel may be given, or entering into the matter of the congress of sanitary architects and engineers, which was held in the Exhibition buildings from the 7th to the 13th of this month, at which a number of very interesting reports were read and discussions raised, mention might be made to the society which took upon itself the duties of organising the exhibition. The idea pervading the formation of this society, in April last, was to found and to make known the professions of sanitary engineer and sanitary architect—professions up to this time unknown in France. The design of the society is to group together engineers and architects taking a special interest in sanitary matters; to discuss in common questions relative to sanitary science; to facilitate the study of sanitary science, and means of application, to young engineers and architects; to encourage the study of the best means of applying practical sanitation to towns and dwellings; to reach by means of the members workmen and foremen, and induce these latter to interest themselves in practical sanitary work; to facilitate, by means of discussion and practice, the development of inventions relating to sanitation; to provoke a healthy competition amongst manufacturers; to reward the creators of new apparatus, contractors, and skilful workmen; and, lastly, to keep the members of the society constantly informed of the work being done in foreign countries by means of communications and publications. Each member should, during the year following that of his admission, address the society on a question relative to the science or practice of sanitation, or a description of some important sanitary work lately completed. The official publication of the society is the *Genie Sanitaire.* Sir B. W. Richardson, president of the Sanitary Inspectors' Association, is a foundation member of this society, and it is hoped that, by means of constant correspondence between the Sanitary Institute and societies of England and the newly-formed French society, to do much good work in the interest of the two countries. The readers of the BUILDING NEWS will be kept well informed of the doings of their French neighbours, and of the interesting novelties and appliances relative to sanitary matters.

Just making a rapid view of some of the exhibits, before entering more into the details of the most interesting, we find a certain quantity of novelties, some put forward as perfect for doing away with all the inconveniences of the Tout à l'égout, and not a small number adapted from English invention or apparatus which has borne the test of experience in England. It is regrettable that English work is not more fully represented at the exhibition, very few of our well-known manufacturers exhibiting.

A sanitary architect, of Laffcrgue, exhibits an automatical apparatus for the evacuation of drainage and waste water. The inventor claims for his apparatus an economy in the quantity of water necessary for the proper flushing of w.c.'s. Again, ordinary river or canal water may be employed, economising greatly the expense which would be necessary if spring water was used. The apparatus is placed at the bottom of each down-pipe, the risk of freezing being thus lessened. All matter falls into this cistern, which is fed by a constant supply of water, and fitted with a siphon on the compressed-air system, allowing periodically a powerful flush, carrying away the contents of the cistern, and at the same time cleansing the near portion of the drain.

The Compound Siphon Co., of College-road, exhibits an installation of the compound siphon of Captain Nadieïn, composed of a series of single siphons of different diameters, each one connected with the other, and ultimately joining that of the largest diameter; a slight quantity only of liquid being necessary for starting the smallest siphon, putting the whole battery into immediate action. This apparatus is specially adaptable for urinals, necessitating only a small feed of cleansing water. The Chamberland filter, system Pasteur, has an interesting installation of the various forms of this filter, which appears to have an increasing success in France. This filter, in its simple form, consists of a metallic tube, inclosing a second tube of porcelain, having an outlet at its lower end. The metallic tube is fixed to the water supply cock, the pressure of the supply forces the water contained between the outer tube of metal and the inner tube of porcelain through the pores of the latter, flowing in a perfectly pure state from the lower orifice, all impurities remaining on the outer surface of the porcelain, which may be easily cleaned from time to time. The filter is also arranged in batteries of three, five, and eight tubes, that of three tubes giving an average supply of 15 gallons per 24 hours.

Another filter, system Breyer, exhibited by Blumenfeld and Co., of Vienna, attracts considerable attention, owing to its powers of filtering and sterilising large quantities of water in a very short space of time, the filter No. 1 exhibited at the Champ de Mars furnishing over 100,000 gallons of filtered and sterilised water per 24 hours. The liquid is sterilised by means of steam jets forced through the apparatus in the same direction as the flow of the filtering liquid. The cost of filtering and sterilising large quantities of water comes to about 3s. for the above quantity. Several portable filters for travellers, &c., supplying three gallons of water per minute, and weighing 15lb., are also on view.

The Society "La Force Motrice Gratuite" has an installation of apparatus for filtering and sterilising water by means of boiling at high pressure. The apparatus consists of a tubular boiler, a changing cylinder, and a filtering reservoir. The water is first boiled at a temperature of 135° Centigrade, and under pressure by means of a steam "bain-marie," and is thus sterilised by the time it has passed under this degree of heat through a series of steam bath boilers; the liquid then passes through the changing cylinder when it is cooled, giving a portion of its heat to fresh supplies of water, which pass through this cylinder on the way to the boiler, thus economising to a large extent the fuel for heating the boiler. At its exit from the cylinder the water is nearly cold, and is sterilised, having now only to pass through the series of filters forming the third portion of the apparatus. A smaller apparatus is made for domestic uses, consisting of a boiler containing about nine pints, and heated by gas or spirit, the second portion of the apparatus being a double reservoir for receiving the sterilised water and supplying fresh water to the boiler, to which is joined an apparatus for filtering. This domestic apparatus extinguishes automatically the gas furnace as soon as the water attains the temperature of 135° Centigrade, and an alarm signal gives notice of this fact, and that the boiling water is ready to be let into the changing cylinder. In the case of a second immediate supply the operation of heating is more quickly performed, and an economy of gas obtained, for the fresh supply of water is, from its contact with the outgoing flow, already heated up to 50°.

The well-known Maignen filter is also represented at the exhibition; the filtering matter through which the water passes is composed of a tissue of asbestos and carbo-calcis.

Howatson and Co. put forward their well-known system of filtration of water for drinking and industrial purposes, the filtering matter for the former purpose being silex and polarite—a porous, spongy, and absorbent mineral substance containing a large percentage of iron, its special properties being its powers of clearing water of all traces of iron or lead, at the same time adding a certain amount of oxygen to the purified liquid. The purification of water for industrial purposes is done by means of a filtering base of broken silex.

Flicoteaux and Co. have an important installation of sanitary apparatus and appliances. They are giving much advertisement to a flushing cistern called the "anti-fuites," or safety against leakage. This apparatus consists of the ordinary floater attached to the supply-cock and the siphon providing the flush. The special portion consists of a dry compartment containing a second floater attached to the supply-cock. In the case of leakage the water in the outer cistern rising above the level of the dry compartment fills this latter, and thus the floater closes the supply before the water has time to rise high enough to give flow to the siphon. No further water supply for flushing can now be obtained until the leakage, from whatever cause, has been repaired. They also exhibit a flushing cistern for w.c.'s containing neither valve nor floater. The siphon flush is produced by pressure on a push-tap placed on a level with the seat, and connected with the cistern by means of a ½in. pipe leading from the supply to the cistern. Pressure on the push allows a quantity of water sufficient to start the siphon to pass from the supply to the siphon.

Bogier and Mothes exhibit a large installation of w.c. apparatus and cisterns, the latest models of which will be interesting to deal with in detail later on. The "Compagnie Anglaise" exhibits all the latest improvements in apparatus and appliances.

Emile Merty, of Bale, exhibits an interesting hydraulic ventilator for private and public buildings. Water under pressure is employed for working this ventilator. With a pressure of five atmospheres a supply of 1,800c.ft. of fresh air per minute may be obtained. The revolving ventilating fan is worked somewhat on the principle of the water-wheel. The jet of water necessary to turn the fan-wheel rapidly is of the diameter of a darning-needle; the supply of water needed with a pressure of five atmospheres being about thirty-five gallons per hour, the waste water may also be re-utilised. The ventilator is very light and compact, and may be fixed in the window or door-frame, in the ceiling or wall, and the inventor claiming that there is no danger of leakage of water, the supply tap may be placed anywhere within reach of the hand.

A warmed w.c. seat, exhibited by Barbas and Balas, is a novelty here. A wide groove made in under side of the seat contains metal wires offering a great resistance to an electric current obtained from a lighting supply, giving to the upper surface of the seat a moderate warmth, which in no case can exceed 30° C. This system can be applied to all existing seats of whatever material.

The Syndicate of Plumbers of the Seine department exhibits the plumbing work done by the apprentices and pupils of the Plumbers' School at Paris. This syndicate has organised an interesting course of lectures and practical classes for sanitary plumbing work, and does a quantity of good work by this means. A. C. Walters, R.P.C., has a number of well-executed samples of plumbing work done at the Shoreditch Municipal Schools.

There are a large number of exhibits of work in iron trellis and cement for drain-pipes of large diameter, walls, partitions, vaults, and floors, several of which systems are earnestly advocated and employed by the well-known architect, M. de Baudot, partisan of the rational system of construction with materials produced by the present age, and fit for the wants of the present time.

Coignet and Co., the well-known inventors and manufacturers of concrete work, constructors of the imitation stone base of the Eiffel Tower, and makers of the concrete stonework for the monumental fountain, balustrading, stairways, &c., for the Exposition of 1889, still existing without any appreciable signs of wear or deterioration, have an interesting installation of samples of such work, and a number of panels of their very successful and artistic Venetian mosaic work.

Boulenger and Co., of Choisy-le-Boi, exhibit specimens of their beautiful artistic ceramic ware and faïence for architectural purposes, such as monumental chimneypieces of faïence, wall-linings of ceramic ware, and several wonderfully-executed and deliciously-coloured specimens of relief panels, vases, pilasters, balusters, and consoles, manufactured in one piece, and suitable for all kinds of decoration in architectural work.

The St. Gobain Glass Co., and the contractors for Paris, Piet and Co. and Henri Mcuret, have very important and complete installations of natural and decorated "Opaline," manufactured by the St. Gobain Co. This interesting material, brought out about two years ago in France, and which has been patented in England and is being introduced into that country, is one of the successes of the exhibition, and attracts much attention from architects and sanitary engineers, owing to its adaptability for a very large number of uses, such as wall-linings for w.c.'s and lavatories, laundries, hospitals, and laboratories; also backs and partitions for urinals and w.c.'s, wall-covering for subways, counters and slabs for butchers' and other shops, lavatory table-tops—in fact, for all uses where marble or other slabs are now employed, and where absolute cleanliness is desired. Of white opal tone, with a hard surface, either with a natural grain or polished, in large slabs manufactured up to a hundred super. feet and more, thus avoiding the numerous joints of tile work, it is said to be the coming material for sanitary purposes. Several very artistic panels of decorated and enamelled opaline are also exhibited, as well as samples of bricks and moulded work of the same material.

Henry Mouret has an interesting exhibition of hollow porcelain bricks and moulded work, enamelled on one or more faces. These bricks have been employed for lining the subways of the first portion of the Seaux railway. They present an exceedingly hard polished surface. The price of £40 per thousand for the bricks enamelled on the narrow side, and £48 for those enamelled on the flat side, appears at first sight rather high.

Elastic emailline is a new anti-salpetrous hydrofuge, invented by A. Bayard. This material is employed for coating the damp walls of w.c.'s, lavatories, laboratories, &c., and may be applied against wood, stone, or cement by means of the brush; it should only be employed for interior surfaces.

A very neat installation of the various sample designs of zinco-tectum, a lately-invented wall-lining of enamel on zinc in very thin sheets of large size, enjoys also considerable success. This material, manufactured by Coubé and Co., and now introduced into England, is much employed for covering the walls of w.c.'s, lavatories, toilet rooms, and all places where walls are damp, or where neatness of effect and great cleanliness are desired. The sheets of zinc being extremely thin are very easily applied to the wall or other surfaces, and being of large dimensions, joints, which for wall-coverings should be avoided as much as possible, are few and far between, and are, owing to the slight thickness of the material, scarcely visible.

The Vallieres alabaster quarries make a strong advertisement of an alum albaster plaster, called "alabastrine," concerning which a paper was read at the Congress. This material, invented in England by Keene nearly fifty years ago, was first patented in France by an Englishman shortly after. It is now largely employed in France for a variety of purposes, coating of walls, stucco-work, imitation stone, and such like. Its price at the works ranges from 3s. 6d. to 8s. the cwt., depending upon the colour.

The Congress of Sanitary Engineers and Architects was held from July 7th to 13th last. On the first day a visit was made to the new works for purifying drainage matter, and the lands destined for spreading purposes at Clichy and Acheres. A visit was also made to the aqueduct of Acheres, inaugurated on the same day. The Congress was opened on the following day (Monday) by the Minister of the Interior. In the morning a report was read by M. Petsche, engineer, on the treatment and utilisation of house refuse; a second report being made by M. George, architect, on the employment of siphoid, stop-valves in the interior drainage of dwellings. In the afternoon communications were made concerning the system of pneumatic drainage at Levallois, by M. Chardon, engineer; the rational installation of fitters in private and collective dwellings, by M. Georgeon, engineer; and a respiratory mask against dust, by Dr. Detourbe. A visit was made to the disinfection station of the Rue des Recollets.

On Tuesday, papers were read, first, by M. de Baudot, architect, on the planning of dwellings and their interior arrangements; the second by M. Morin-Goustiaux, architect, on the necessity of an efficient control over the sanitary inspection of dwellings. In the afternoon a visit was made to the works of the Société de Salubrité, at Levallois-Perret. On Wednesday, a report was made by M. Philippe, engineer, on "Public Baths," M. Jourdain, town engineer, reading a paper on the rules and regulations of public roads and streets. In the afternoon, M. de Baudot conducted the members of the Congress to the Sevigné school for girls, a building constructed by this architect after his much-studied ideas of rational design and construction. An interesting visit was afterwards made to the Paris drains and catacombs, the day's work ending up with a banquet on the first platform of the Eiffel Tower. A visit was made on Thursday to the slaughter-houses of the Villette, where an inspection was made of the various modes of killing. In the afternoon, communications were made, by M. d'Anthony, engineer, on the system of heating schools; by M. Pignant, engineer, on the necessity of a sanitation law in France; by M. Bougarel, on the system of purifying drains; house refuse, by M. Bonvellain, engineer; the rearrangement and utilisation of drainage work existing in towns not yet properly drained, by M. Montricher, engineer; and three examples of the utilisation of waste water outside Paris, by M. Lacau, architect. On Friday, M. Cacheux, engineer, read reports on the evacuation of waste water in small towns and villages; M. Ch. Gautier, architect, on the rational system of heating and ventilation of dwellings; also several minor communications in the afternoon. The proceedings terminated on Saturday by papers on the interior and exterior sanitation of cheap dwellings, by M. Charles Lucas, architect; the organisation of a professional teaching in sanitary matters, by M. Benouville, architect; and several minor discussions in the afternoon.

Summaries of the most interesting reports will be given, with the discussions or important communications made by the members of the Congress.

Paris, July 22. ARTHUR VYE PARMINTER.

SALISBURY CATHEDRAL.

SIR ARTHUR BLOMFIELD has reported to the Dean and Chapter that unless repairs of two turrets of the central tower are immediately commenced the tower and spire of Salisbury Cathedral will be most seriously endangered. The work is strictly a work of repair, not of restoration, and no feature of the tower and spire will be injured, under the careful superintendence of Sir Arthur Blomfield, and Mr. Thompson, the contractor, who has so skilfully succeeded in similar works elsewhere.

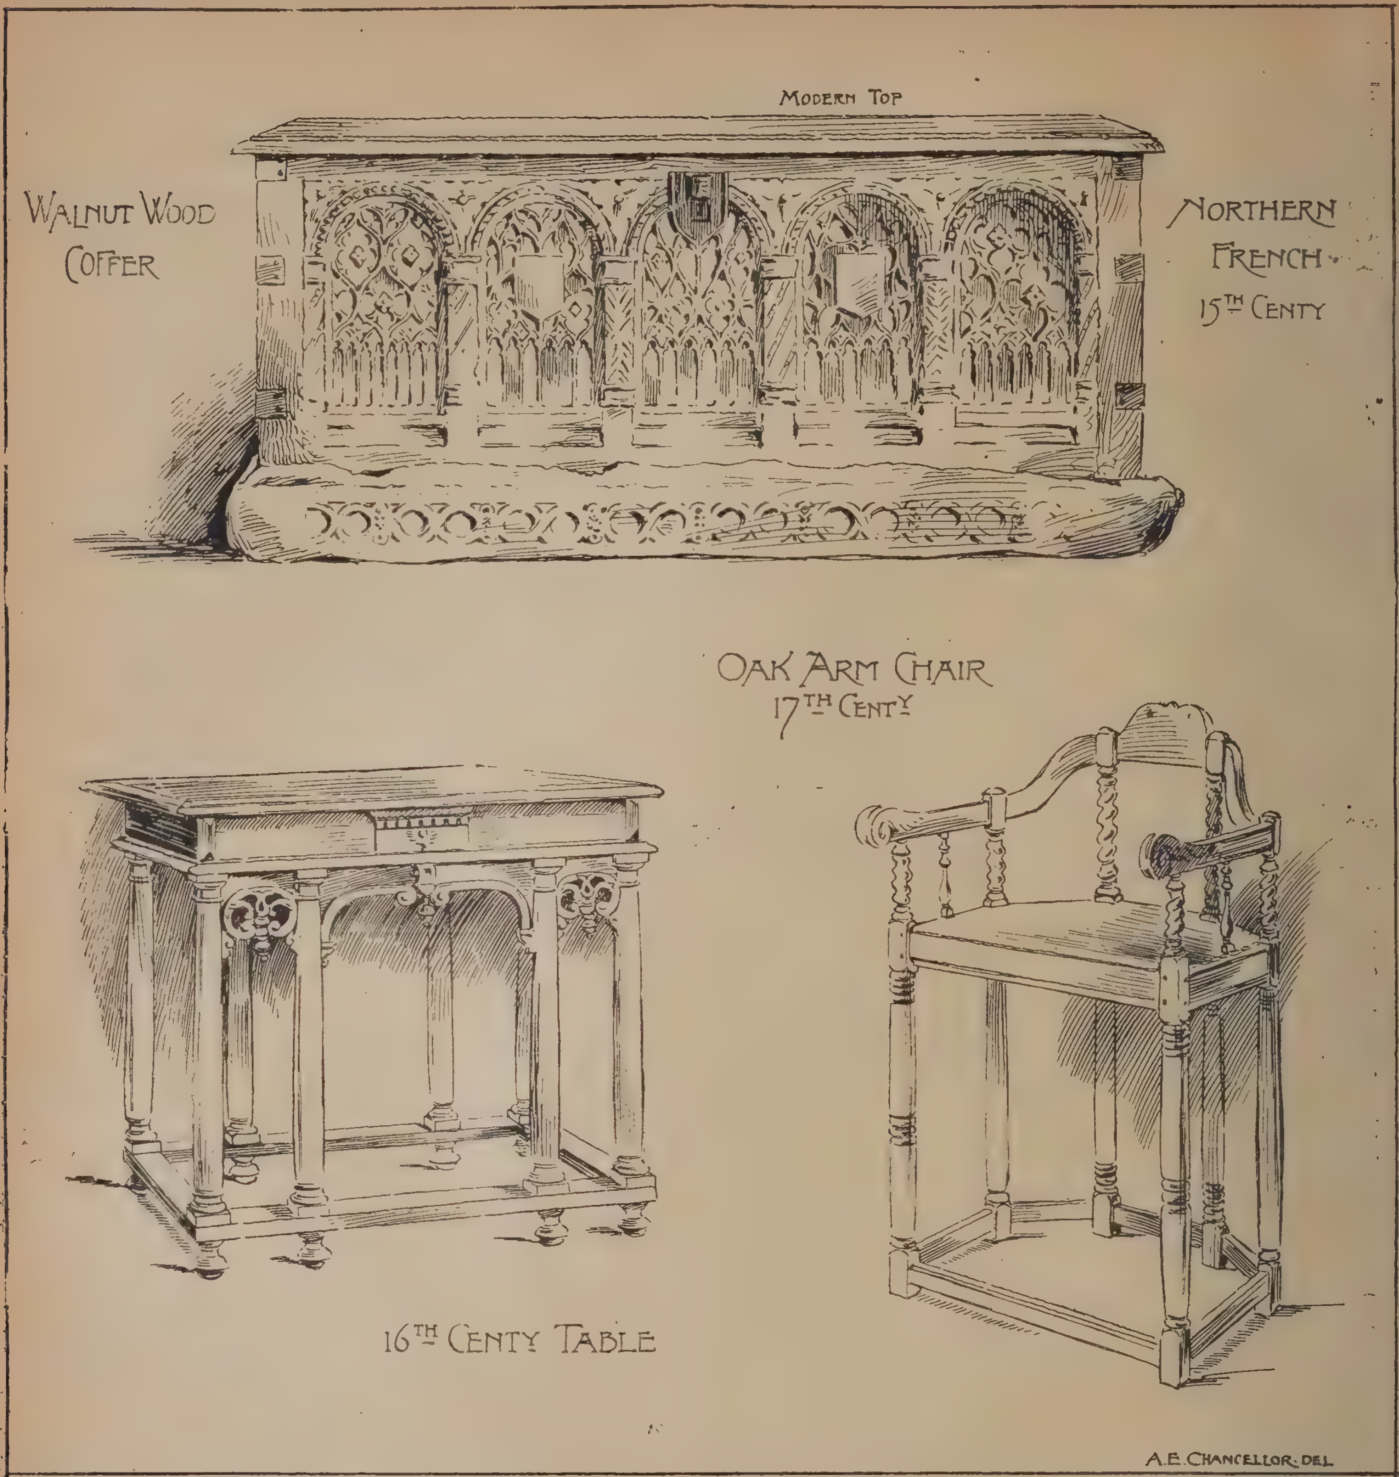
To complete what Sir Arthur Blomfield suggests will involve an expenditure of at least £5,000. From the funds intrusted to their care for the fabric of the cathedral, the Dean and Chapter are only able to promise £500 in two years, and the Bishop, the Dean, and Chapter, and members of the Greater Chapter have already undertaken to give £800 in two years. The Dean therefore hopes that he may be assisted by the contributions of those who are anxious to preserve so noble and interesting a memorial as the tower and spire of Salisbury. The following is Sir Arthur Blomfield's report:—

"During the progress of certain minor repairs in the central tower it became evident that something was seriously amiss with the upper part of the two western stair turrets which required investigation. A scaffold was accordingly erected round the north-west turret, from which a close and careful examination has been made, with the result that its state proves to be even worse than was feared. A good deal of the external stonework is split and fractured and is in so loose and unsafe a condition that no assurance can be given of security from some serious disaster which might at any time occur. Certain cracks which are observable internally, especially one in the base of the spire at this angle, though they are certainly not altogether new, show indications of a slight recent movement which would inevitably become dangerously aggravated by any considerable fall of portions of the external stonework. It is difficult to determine with certainty the precise cause of the present state of things in these turrets, but various adverse agencies have, no doubt, been gradually at work for many years past. Of these the principal are, first, the numerous iron bands, rods, and ties which have been introduced from time to time, many of them in the most injudicious manner. An attempt has been made to protect some of them with lead from wet and consequent corrosion, but this has in many places altogether failed and made matters worse rather than better. The next agents are wet and frost, which have gradually done much damage; and the third is to be found in the great thrust of the spire, which is continually active. Nothing can be done to lessen or modify this last element of danger, but it is imperative to render the angle turrets, which receive so much of it, as sound and strong as they can be made. For this purpose any attempt at small repairs or patching would not only be useless, but positively dangerous. The work that is called for by the necessities of the case is emphatically not one of restoration, but of repair, which is absolutely essential for safety, and which to be effectual must be complete and thorough. The greatest care, caution, and skill will be necessary in dealing with the damaged portions of both these turrets. I should recommend the completion of the north-west turret first, to be followed immediately by the repair of the corresponding one on the south side. It is impossible to give any accurate estimate of the cost of the work necessary to put these turrets in a sound and satisfactory state, but it will probably amount to about £5,000."

THE ENGINEERS' AND ARCHITECTS' SANITARY CONGRESS IN PARIS.

THE newly-constituted Society of Sanitary Engineers and Architects of France have been holding a congress at the International Exhibition of Hygiene in Paris. Though not strictly speaking an international congress, some Dutch, Belgian, and British sanitarians attended. The latter, to the number of 16, included 10 sanitary inspectors from different London districts.

The idea dominating the organisation of the congress seems to have been, says a *Times* correspondent, that hygienists had terminated their mission, had solved the problems affecting public health, and that the time had now come for practical men to apply the theories evolved by the hygienists. The speeches of the congress, nevertheless, showed that various most important sanitary problems were far from settled, and that the practical men were not as yet forthcoming with practical measures. Thus on the disposal of household refuse no emphatic opinion was pronounced, some speakers preferring destruction by fire, others utilisation for agricultural purposes; the only real agreement being that railway companies should reduce their charges for transferring the contents of dustbins to rural districts. In respect to domestic drains, no agreement could be arrived at as to whether there should be an intercepting trap between the house and the sewer, or whether every soil-pipe should be utilised as a sewer ventilator. On the other hand, papers were read before the congress proposing all manner of contrivances to economise the use of water in drains. A good deal was said about the control of the plumbing and sanitary work in dwellings, a duty generally left to the municipalities; but little was said as to the incapacity of the many municipalities who, in France at least, know little or nothing of sanitary matters. It was, however, agreed that the technical schools of sanitary plumbing established in Paris should be encouraged, and a diploma of capacity should be given to the students after examinations following on three years' training. It was also agreed that a chair of hygiene should be established in the schools of architecture. Such teaching is, however, already given in some of the schools of architecture. There was a very lengthy discussion as to the rules that should govern private thoroughfares, and it was finally decided that such thoroughfares, if frequented by the public or inhabited by several individuals, should be subjected to the same regulations as public roads. But the congress could not come to any understanding as to height of houses in proportion to the width of roads. To the proposal that the window of every inhabited room should receive direct rays of sunlight, M. Bechmann, chief engineer of the town of Paris, replied that it was not possible to pull down the whole capital of France so as to conform with the decisions of the congress. There was a very interesting debate on the heating and warming of dwellings, when M. Emile Trélat's well-known theories were very generally approved. Stoves were very energetically condemned and steam-pipes widely commended. The principle of open windows, of cold air but warm walls, was unanimously



EXAMPLES OF EARLY FRENCH · FURNITURE · FROM THE "PAYRE" COLLECTION · AT · S·K·M·

approved, but the difficulty of application equally recognised. M. Emile Trélat thought that even unhealthy portable stoves might be employed to superheat a room, on condition that the stove was removed and the windows thrown wide open before anyone entered the room. Resolutions were also passed in favour of giving douches in all schools, of building cheap working - class dwellings, and other similar measures. The members of the congress visited the pneumatic drainage works of the Société de Salubrité at Levallois-Perret, and discussed at some length the Liernur system of drainage. The congress also visited the model disinfecting station in the Rue de Récollets, the Paris sewers, the slaughter-house and cattle-market at La Villette, and were entertained at a banquet on the Eiffel Tower. Altogether upwards of 300 members joined the congress, for the most part architects and engineers.

* * *

Six memorial-stones have been laid of an enlargement of the Antley Wesleyan chapel and school premises, Accrington, which is to cost about £3,000.

EARLY FRENCH FURNITURE FROM THE PAYRE COLLECTION.

In last week's "B. N." we gave a notice of this remarkable collection now on exhibition at South Kensington. The Coffer, elaborately carved in walnut-wood, is a fine specimen of the 15th century, and though considerably decayed about the plinth, the rich Gothic tracery is in a good state of preservation. It comes from the North of France, is 5ft. 6in. long, and 2ft. 6in. high; the top is the only modern portion. The framework has been bound with iron angle-pieces to keep it together. The small Table, also in walnut, with its eight circular and slightly tapering columns supporting the top, is 16th-century work. It is 3ft. 1½in. long, 1ft. 7½in. wide, and 2ft. 9in. high, and contains one long drawer. The oak arm-chair, of quaint and unusual design, is worthy of a place in any museum. The arms and back are remarkably low, giving the seat an appearance of greater height, although it is only 2ft. from the ground. Two of the small balusters from the raking pieces in the back are broken away. The chair is 2ft. wide, and the depth of seat is 1ft. 2in.

OBITUARY.

The sudden death is announced, at the advanced age of four-score years, of Mr. **Samuel Hemming**, formerly and for many years in practice as an architect—first in Parliament-street, Westminster, and subsequently in Temple-row, Birmingham. Mr. Hemming, who had retired from the profession, died on Thursday, the 18th inst., at 81, Stockwell-road, Brixton.

* * *

At the half-yearly meeting of the Liverpool Tramways Company, on Saturday, it was reported that the directors had just let the contracts, amounting to £7,694, for constructing an extension of the tramways from the Bootle boundary to Litherland bridge, being a length of about 1,303 yards; and from Everton to Walton-road, thus connecting Breck-road, Everton, with the North Docks, a length of 1,236 yards; and also 290 yards length of tramway line in Oakfield-road, connecting the company's Belmont-road lines with those of the city. The total length of these extensions measures about 1 mile 1,609 yards, the contract price being only a little over £4,500 a mile.

NEW MUNICIPAL BUILDINGS, COVENTRY.—NEW BANK AT HALIFAX.—R.I.B.A. SILVER MEDAL DRAWINGS OF LLANDAFF CATHEDRAL.—"OUR HOMES," BY R. BARRY PARKER.

Our Illustrations.

COVENTRY MUNICIPAL BUILDINGS COMPETITION.

(For description and sketch plans of first premiated design see pp. 110 and 111.)

NEW BANK, HALIFAX: SELECTED DESIGN.

The new banking premises about to be commenced for the Halifax and Huddersfield Union Banking Company is an outcome of an open competition in which prizes of £100 and £50 respectively were offered. Forty-three sets of designs were sent in, and Messrs. Horsfall and Williams, of Halifax, were awarded the first prize of £100, and have been intrusted with the carrying out of the work; Mr. Mitchell Withers, of Sheffield, winning the second premium of £50. The architects' detailed estimate for the building was £12,000, and the contracts have been let for £20 within this figure. The whole of the three principal elevations will be of cleansed ashlar, from quarries in the neighbourhood; the four circular columns supporting the front entrance pediment being of polished red granite. The entrance vestibules will be finished in Doulton ware, and the pavements of all vestibules, corridors, and public portion of large banking hall will be of mosaic, the remaining being of oak blocking. It is intended that the premises be used solely for a bank, and they will therefore be of two stories only. The ground floor is set apart for the large central banking-hall, which is surrounded by manager's room, having three waiting-rooms adjoining, and sub-manager's room overlooking the administrative, directors' room and offices, accountant's office and book safe, bullion and plate safe, calling-over room, clerks' and keeper's entrance and offices, and an additional lavatory being provided for the public. The first-floor plan, surrounding or flanking the banking-hall on three sides is set apart for book-stores, manager's private rooms, and the bank-keeper's residence. The large hall will be lighted by a large dome-light of coloured glass, and the walls will be pilastered, panelled, and decorated with fibrous plaster, and the fitting will be of wainscot oak. The site of bank is in the most commanding position in the town, the style of architecture adopted being Classic, and the drawing which we reproduce herewith is hung in the present Royal Academy Exhibition.

LLANDAFF CATHEDRAL WEST FRONT: R.I.B.A. MEDAL DRAWINGS.

We have already, in the Building News for the 12th inst., published the plan and several drawings made by Mr. J. H. James of this great Welsh cathedral. We then gave a short account of the history of the building. To-day, from the same series of drawings, for which a Medal of Merit was awarded by the Royal Institute of British Architects, we print a large scale detail of the west front as measured and drawn on the spot. The sections of mouldings freely figured, with full dimensions to every part, will be appreciated by our practical readers, as they must be by everyone who cares for the study of our national architecture of the Middle Ages.

"OUR HOMES."

(For further sketches and descriptive article see pp. 105-8.)

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

Northern Architectural Association.—The annual excursion of this association was held on Saturday last at Chesters, the residence of Mr. N. G. Clayton. The following twenty-one gentlemen from Newcastle, Sunderland, South Shields, &c., were present:—Mr. F. W. Rich (vice-president), Messrs. J. H. Morton, J. T. Cackett, A. B. Plummer, E. Shewbrooks, W. Glover, F. Caws, H. Grieves, H. C. Charlewood, G. T. Brown, W. Hope, H. Gibson, C. S. Errington, H. Cayley, H. Oswald, R. Morton, E. J. Watson, M. Martinson, R. Sisson, and R. Rich. Mr. Robert Blair, F.S.A., was also present with the party during the day, and conducted the members over the remains of the Roman station of Cilurnum, and explained the plan to the members of the association. Mr. Rich conducted the party over the new buildings, and explained that Chesters has been in possession of the Clayton family for about 90 years. It was originally built by the Erringtons. Some additions were made to it, chiefly in a portico on the north side in Mr. Dobson's time. The present owner, Mr. N. G. Clayton, has had extensive alterations made. The old mansion house has been gutted and nearly rebuilt, and forms a very small portion of the mansion of to-day. This is built of stone throughout from the neighbouring quarries, is lighted by electric light, generated by Mr. Clayton's own installation, and is supplied with water from a never-failing spring about three miles away. Chesters is a great storehouse for Roman antiquities, standing as it does on one of the Roman stations, and a great number of objects of antiquity are cared for. Before the present additions, these were partially stored in one of the rooms of the house, partly in the portico, and other places. Mr. Clayton, however, has now built a museum near the entrance lodge, in which to store all the objects of antiquity. New stables have been built a short distance from the house with all the modern improvements. A new carriage drive is also being made, with entrance lodge and gates. The contractors for the work have been Mr. Walter Scott, of Newcastle; Messrs. Middlemiss Bros. for builders and joiners' work; Mr. Civil, of Hexham, for part joiners' work; Messrs. Watson and Sons, Newcastle, for plumbers' work and heating; Mr. Smith, of Hexham, for part plumbers' work; Mr. Baty, of North Tyne, and Mr. Charlton, of Stamfordham, for tiling and slating; Messrs. Wilkinson and Co., for plasterers' work; Mr. Ellis, of Hexham, for painting and glazing; and Messrs. Musgrave and Co., for stable fittings. The mansion has been carried out from the designs of Mr. Norman Shaw, of London, and the rest of the works in museum, entrance lodge, gates, stables, houses for coachman, gardener, &c., from designs by Mr. Frank W. Rich, of Newcastle-on-Tyne. After dining together at the George Inn at Chollerford, the party returned to Newcastle by the 8.25 p.m. train.

Somerset Archæological Society. — The forty-seventh annual meeting of the Somerset Archæological Society is being held in Bath this week, and has extended over three days. The proceedings opened on Tuesday, when Mr. H. D. Skrine, this year's president, took the chair at the annual meeting at the Royal Literary and Scientific Institution, which has been chosen as the headquarters of the association during the meeting. Mr. F. T. Elworthy read the report of the council, which stated that the society numbered 569 members, though the balance in hand had been reduced to 17s. 2d., against £49 4s. 2d. the previous year.—Sympathetic references were made to the deaths of Sir Jerom Murch (who was president of the meeting held in Bath nineteen years ago), Mr. Moysey, and Colonel Ewing. Nineteen new members were elected, and Mr. E. B. C. Trevellan (retiring president) and the Bishop of Bath and Wells were added to the list of vice-presidents. The president's address, which was of considerable archæological interest, dealt with the occupation of Hampton and Claverton Downs just outside Bath by the Belgic conquerors of the south of England.—After the annual meeting the Mayor entertained the society to luncheon at the Guildhall, and the afternoon programme included an inspection of the Roman remains and recent discoveries, as well as visits to the Abbey and Museum.—In the evening a meeting was held at the Literary Institution for papers and discussion. The Dean of Wells (Dr. Jex Blake) presided. Rev. Canon Church read some interesting notes which he had made on the cartulary of the Priory of SS. Peter and Paul, Bath. Rev. T. S. Holmes gave a paper written by Bishop Hobhouse on a map of the forest of Mendip; and the Rev. F. W. Weaver read some of the late Sir John Maclean's notes on the Clyveden family of Somerset. An excursion was made on Wednesday to Great Chalfield church and manor-house, Bradford-on-Avon parish church, and the Saxon church at Bradford; the Bridge Chapel, Kingston House, and the 14th-Century Barn having been viewed, Westwood church and manor-house, Hinton Abbey, Charterhouse Hinton, were also seen. Yesterday (Thursday) the first place visited was Chapel Farm, Lansdown, viewing the site of the battle of Lansdown, the camps, and the monument of Sir Bevill Grenville, thence to Cold Ashton church and manor house, and on to Marshfield church. The party then proceeded by Bannerdown and Batheaston, to Claverton Manor, and the camps in the neighbourhood.

CHIPS.

A new organ has recently been built by Messrs. Abbott and Smith, of Leeds, for the Church of St. Lawrence, Adwick-le-Street, near Doncaster, at a cost of £310. The dedication took place last week.

The Duchess of Albany opened at Leatherhead, last week, a three-days' bazaar in aid of the funds for restoring the tower of the parish church. The work of restoration is being carried out under the supervision of Sir Arthur Blomfield, and is estimated to cost nearly £2,000.

The Improvement Committee of the City Council of Birmingham finally considered, on Tuesday, the applications for the post of secretary and manager of the department, rendered vacant by the resignation of Mr. A. H. Davis. Originally there were 222 applicants. Of this number the committee last week selected four, and of this four they yesterday selected Mr. Peter Addie, of Fairhead, near Lytham, for the office. Mr. Addie is thirty-five years of age, has had large experience of the management of property, and for five years was steward to the Swansea Corporation.

Memorial-stones were laid, on Tuesday, in connection with the new district council chamber and public offices at Coseley. The building will consist of two stories. The old local board room, on the ground floor, will be converted into offices for the surveyor, sanitary inspector, and rate-collector, with hall and corridor; and the floor above, which will be an entirely new structure, will comprise a council chamber and an office for the clerk to the council. The work is being executed by Mr. T. Jones, of Roseville, to plans prepared by Mr. C. W. Shackleton (surveyor to the council), and will cost £450.

The half-yearly report of the City and South London Electric Railway states that in accordance with the resolution passed by the shareholders, plans have been prepared for the extension from King William-street, City, to Moorgate-street, and negotiations have been opened for acquiring some of the property involved. The line will diverge from the existing system at the Borough High-street, and proceed under the Thames by entirely new tunnels, a little eastward of the existing ones under the river. Preliminary borings have also been made in preparation for the authorised southward extension of the system from the present terminus at Stockwell to Clapham Common.

A service of thanksgiving has been held at Toppesfield Church, near Halstead, Essex, to celebrate the completion of some important repairs and improvements to the fabric of the building. The works carried out comprise the renewal of the whole of the windows in the nave in stone, and reglazing of them; a new east window in the chancel, of stone, the one removed having been constructed of wood. The original stone tracery being completely destroyed, it was found necessary to erect an entirely new window. The gallery in the south aisle has been removed, and the seating accommodation has been rearranged in the aisle. The old stone porch is being restored, but is not yet quite finished.

DESIGN FOR THE LIVING ROOM IN A HOUSE WHICH HAS THIS ROOM, SCULLERY, A LITTLE SANCTUM, PANTRY, LAVATORY, AND BEDROOMS ONLY.

Building Intelligence.

Edinburgh.—The Town Council of Edinburgh, at their meeting on Tuesday, ordered a block bill to be prepared for the extension of the city boundaries and the amalgamation of Edinburgh, Leith, and Portobello, and plans were submitted for the extension of the city chamber. By these plans the proposed new council-room, to occupy the first floor at the north-west corner of the Exchange-square, would, with galleries, have three and a half times the cubic capacity of the present chamber; the proposed new burgh court-room, on the floor level, under the new council-room, would be double the size, and have twice the cubic capacity of the existing court-room; much-needed additional accommodation would be provided in the town-clerk's and chamberlain's departments. An amendment that a more comprehensive scheme be devised, in view of the amalgamation of authorities, was rejected by 23 votes to 4, and it was decided that the scheme be sent back to the Lord Provost's committee for further consideration, and, if so advised, getting an estimate for the block immediately adjoining the present buildings on the west side of the square.

Exeter.—The new wing of the Albert Memorial Museum, Exeter, was opened on Friday last by the Duke of Devonshire. The style deviates slightly from that of the old building. The walls are of Pocombe stone with Hamhill dressings; the huge columns in front are of Devonshire granite polished. The tracery of the windows is of Hamhill stone. From the main entrance of the museum in Queen-street there is a passage way, on each side of which there is a class-room, 30ft. by 22ft., with wooden dados and floors of wooden blocks, which have been used throughout. On the Paul-street side there is a spacious museum-room, 57ft. 9in. by 41ft. 6in. Upstairs and immediately above this museum-room there is a very large apartment set apart for the art gallery. Upstairs there are also two well-lighted lecture-rooms, one about 48ft. by 22ft., and the other 48ft. by 27ft., both to be used for lectures in connection with the technical college. The chemical and physical laboratories, a portion of which was erected by means of the Jubilee fund in 1891, have been extended by the aid of the Kent-Kingdon bequests. There is now a lecture-room for teachers of chemistry, precisely the same size as the chemical laboratory, but not as yet fitted with students' benches. The architects are Messrs. Fulford, Tait, and Harvey; the builder is Mr. Woodman. Messrs. Easton and Sons supplied the stonework. The carving in connection with the new additions has been carefully and skilfully carried out by Messrs. Harry Hems and Sons, ecclesiastical sculptors, of Longbrook-street, Exeter.

Hackney New Free and Parochial Schools.—The foundation stone of these schools was laid last Monday week. The building, which is to supersede the old schools in Chatham-place, which has an unbroken record since 1714, is two stories high, and is designed to accommodate 300 boys and 300 girls. It is provided with a school-room and three class-rooms on each floor, with cloak-rooms at the rear near the entrances. The school is planned and fitted up to date in all requirements. The amount of the contract is £7,704. Mr. Alfred Cox, of 37, Baker-street, Portman-square, W., is the architect, and the contractor is Mr. W. Shurmur, Riverside Works, Upper Clapton, N.

Handsworth.—The new church of St. James at Handsworth was consecrated for public worship by the Bishop of Lichfield on Tuesday. The old church, which dated back to 1838, was not only inadequate in size, but in its interior arrangements it was entirely out of harmony with present-day ideas. The services of Mr. J. A. Chatwin, architect, of Birmingham, were accordingly requisitioned, and he submitted designs for the rebuilding of the greater part of the church. The original structure was an unattractive building with a huge gallery, very deficient in ventilation. Mr. Chatwin's proposal was to remove the old gallery and add a new nave, chancel, south aisle, baptistery, and organ chamber, at a cost of about £7,000, and, his designs being approved, the work was commenced about twelve months ago. The style of the open work is Geometrical Gothic. The old church now forms the north aisle, and the chancel becomes a morning chapel. Seats are provided for a congregation of about 1,200, or 350 more than could be accommodated in the old edifice. A debt of about £3,000 remains on the building fund. The baptistery at the west end and a south porch have yet to be added. The contract for the work was carried out by Messrs. Barnsley and Son, of Birmingham.

Landrake.—St. Peter's, the venerable parish church of Landrake, has had in the shape of a handsome reredos a seemly addition to its interior. The material of which the reredos is made is veined and polished alabaster, but the panels and statues, however, are of Castellino marble of the finest whiteness. Rising from the floor of the chancel, the principal portion of the reredos proper is, up to the massive retable, of plain polished alabaster. Upwards from this point the structure is divided into five compartments, of which the middle one is the largest, and each forms a niche or recessed panel. Filling the central one is a figure of our Lord ascending in the midst of glory surrounded by a vesica piscis, His right hand raised as if bestowing a blessing. The recesses on both sides contain statues of the Four Evangelists. The sculptors were Messrs. Harry Hems and Sons, of Exeter.

Richmond, Surrey.—The foundation-stone of the technical institute and secondary school now being built in Selwyn-avenue, Richmond, for the Surrey County Council, was laid by the Duke of Cambridge on Wednesday afternoon. The object of the building is to provide an efficient modern education in science, art, manual work, and commercial subjects during the day, for 350 to 400 scholars, and to serve all the purposes of a polytechnic, including women's classes in the evening. The premises will cost, when completed, £6,467. The portion now being erected will cost £4,626, towards which the Richmond Town Council contributes £1,250, and the Department of Science and Art £650, leaving the balance to be obtained from the County Council and subscriptions. The County Council, besides its grant of £2,500, has purchased the site costing £1,577, to the amount of close upon £500 a year. Chemical and physical laboratories, a school of art, class-rooms for carpentry, carving, and plumbing are all included in the portion now to be erected. This will be one of a series of new technical buildings erected or being erected by the County Council in the seven principal towns of the county, at a cost of over £20,000, supplemented by votes of nearly £6,000 from local rates or subscriptions. The architects were Messrs. Fryer and Barr, of Queen Anne's Mansions, Westminster.

Royal Free Hospital.—The Prince and Princess of Wales and their daughters visited the Royal Free Hospital, Gray's Inn road, on Monday afternoon, and the Princess opened the new front building, which is to be called the Alexandra Wing. The new front completes the reconstruction of the hospital, which was established in 1828, and now contains 160 beds. The cost of the new buildings, including a laundry at the rear, re-construction of the drainage system, fire-extinguishing appliances, and other necessary improvements, has been about £30,000, towards which sum £26,000 has been raised. The new buildings, which front on the Gray's Inn-road, have been designed by Mr. W. Harvey, and carried out by Messrs. G. H. and A. Bywaters and Sons.

* * *

The Secretary of State for Foreign Affairs has received a copy and translation of a notice issued by the municipality of Vienna, calling for tenders for plans, construction, and working of a network of electric railways in and round that city. The tenders must be sent in before the 14th of November next. The notice may be seen at the Commercial Department of the Foreign Office, S.W., between the hours of 11 and 6.

An inquiry was held at the Temperance Hall, Ossett, on Tuesday, by Colonel W. M. Ducat, R.E., of the Local Government Board, into an application by the Ossett corporation for sanction to borrow £3,300 for extending the Eastern Outfall Sewage Works. The works will deal with the sewage of a population of about 7,000 persons. They were constructed eighteen years ago from the designs of Mr. M. Paterson, C.E., of Bradford, and deal with an average of 300,000 gallons of sewage in twelve hours. In consequence of the growth of the borough, the corporation found it advisable to enlarge the works. Mr. Paterson was again consulted, and has prepared plans for the enlargement. Additional settling tanks, with a capacity of 180,000 gallons, are intended to be provided, and six or seven acres more land laid out for filtration purposes.

COMPETITIONS.

West Ham, E.—The Technical Institute competition, for which somewhere near seventy designs were received in June, is not likely to be settled for another month, so those who are interested in the contest may enter upon the holiday season without any undue anxiety as to being suddenly recalled to town to receive the premiums. Unforeseen difficulties have rendered it impossible to place the designs submitted in the hands of the assessor earlier than the 1st of August; but it is hoped that the result of the competition will be made known during that month.

CHIPS.

Mr. Ernest A. E. Woodrow, A.R.I.B.A., upon his retirement from the Theatres Branch of the London County Council, has accepted the invitation of the Actors' Association to become their honorary consulting architect. The appointment, we learn, was offered him by the council of the Association, upon the suggestion of Sir Henry Irving, on account of Mr. Woodrow's intimate knowledge of the requirements of theatres.

Messrs. Fambrini and Daniels' Architectural Concrete Works, Lincoln, are now supplying a series of decorative pierced panels for the new lifeboat house, Whitby, Mr. W. T. Douglas, Westminster, architect. Some of the above panels are over 15ft. long, cast in one piece, and are to be in a very exposed position. This firm have also appointed Messrs. Butson and Roberts, 67 and 69, Chancery-lane, W.C., as their sole agents for London and districts.

The Parks and Galleries Committee of Glasgow Town Council considered, on Tuesday, an offer from the trustees of the Bellahouston estate offering it for sale for £50,000. The committee drove to the estate, which extends to 170 acres, and the opinion was expressed that it would form one of the finest public parks in Scotland. Ultimately the committee unanimously agreed to recommend the council to accept the offer. The estate is situated south-west of the City and immediately to the south of Govan.

The steam tramway between Rye and its rising marine suburb, Camber-on-Sea, was completed last week, and was opened on Saturday afternoon.

The latest discoveries that have been made in the course of the excavations at the ancient temple of Delphi comprise a head of Hera, from a marble statue of that goddess belonging to the Classic period of ancient Greek art; likewise the marble head of an ox. Both pieces are in an excellent state of preservation, and have been deposited in the museum at Delphi.

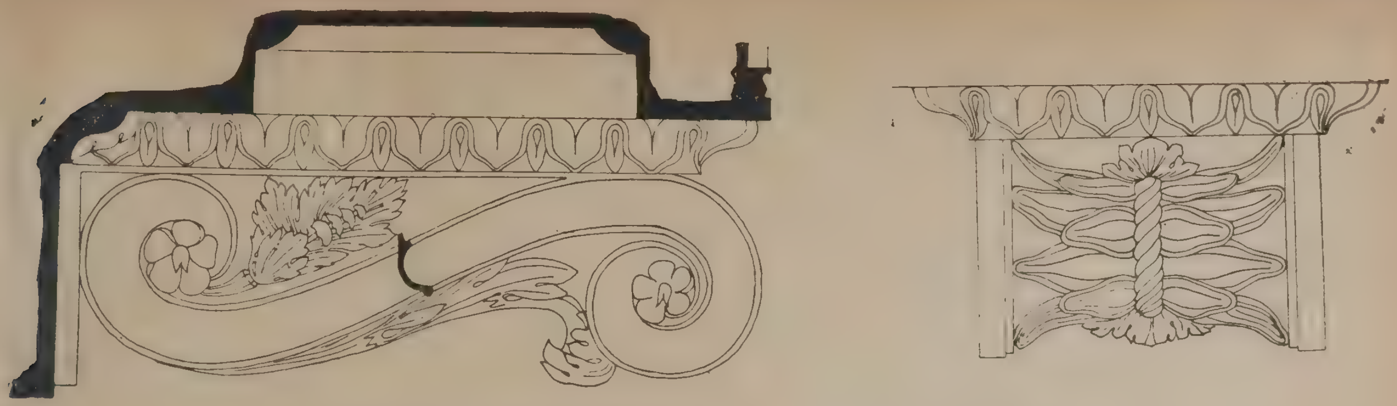
Signor Spartaco Vela, painter, son of the celebrated sculptor, Vincent Vela, has died at his native village of Ligornetto. He has bequeathed to the nation a châlet containing a gallery of art treasures, which is famous chiefly for a collection of the father's works.

Mr. Joseph Robson, of the firm of Messrs. Nowell and Robson, builders and contractors, Kensington, died at his residence, 22, Kensington-crescent, on Wednesday, aged 62 years.

At the half-yearly meeting of the London Brighton, and South Coast Railway, held on Wednesday, the chairman announced that the preliminary works on the new line between Croydon and Earlswood, including the long tunnel (parallel with the existing main line belonging to the South-Eastern Company), will soon be commenced.

On Saturday afternoon the corner-stone of the new south transept of St. Clement's Church, Chorlton-cum-Hardy, was laid with Masonic rites. The church itself, which replaced an ancient structure, was built some thirty-five years ago. A north transept was afterwards added, and the addition, of which the corner-stone was laid on Saturday, is a replica of it. It will provide accommodation for over one hundred worshippers, and will cost about £1,500. The architects are Messrs. W. and G. Higginbottom, of St. Ann-street, Manchester.

The Dean of Guild Court of Edinburgh have just passed plans for altering one of the few remaining ancient buildings of the High-street. The tenement adjoins the assembly hall, and was purchased last year for the Church of Scotland. It is situated in a court known as Boswell's Court, so called from one Dr. Boswell, who lived there about 1760. The plans now passed will complete the improvement scheme of the assembly hall. The architects, Messrs. Hardy and Wight, have provided on the two lower floors ample accommodation, much needed by the assembly. Committee-rooms, conversation-rooms, &c., and the two upper floors are arranged as commodious dwelling-houses. The external aspect of the old building will be carefully preserved in all characteristic features, and the rough walls roughcasted and repaired.



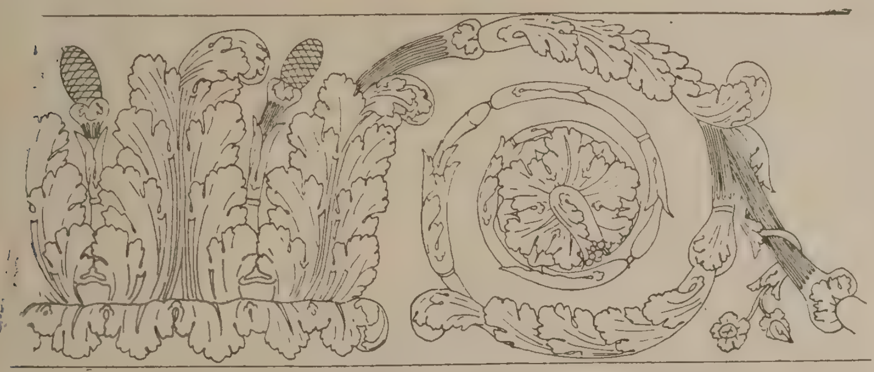
Cornice Console, Temple of Jupiter Stator, Rome. (From Taylor and Cresy.)

CLASSIC DETAILS AND THEIR APPLICATION.*

By G. A. T. Middleton.

V.—CLASSIC TIMES: THE CONSOLE AND THE SCROLL.

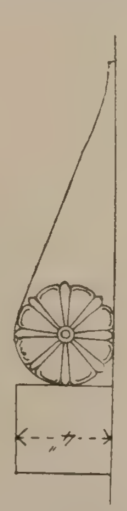
WHILE the cornice was usually the crowning feature of a building, yet even in Egypt, in the Theban period, it was commonly found also over the doorways to pylons and tombs, serving no other purpose than to mark these entrances; and from the few indications we have left to us, we infer it to have been similarly employed by the Greeks, knowing it to have been so used, at least, in the one Ionic example of the Erechtheium. In Egypt, however, the simple cavetto cornice, with its enrichment of the carved winged globe, was simply planted upon the face of the wall, and this want of apparent support was just the description of artistic blot which the Greeks would naturally be expected to remedy. The means adopted was that of the vertical truss or console projecting out of the masonry on either side of the door, which, while serving no constructional purpose, just satisfied the æsthetic needs of the case. The example illustrated herewith, from the Island of Kos, is of uncertain date, and exceptionally simple outline and small size; but these which flank the Erechtheium doorway are elaborate in their ornamentation, with crisply-carved acanthus leaves, and with a detached anthemion filling up the angular space under the volute of the truss, much as the bud does under the spiral in the Corinthian capital at Epidauros, already illustrated.



Portion of Frieze Scroll from the Maison Carrée at Nismes.

A detail like this, occupying a definite position to which it was well adapted, was not likely to be neglected by the Romans. Using it in its proper position, they produced several good examples, amongst the best being that upon the highly-refined Maison Carrée at Nismes—a building which, in spite of its late date, remains to us as one of the best of the Roman Empire, and upon this console, as illustrated, the use of projecting acanthus rosettes in the eyes of the volutes, and of the plaited hair ornament in bands down the front are noticeable, as is the form of the anthemion in low relief. Long before the date of this building, however, the Romans had employed the console elsewhere. In the Arch of Titus it is found forming the keystone to the great arched opening, and supporting the cornice over—a most questionable position for its employment when the order was a decoratively applied order only, presumably carried by the columns at the side, and not by the arched construction. More frequently, however, it is found with its greatest length horizontally in buildings of the Corinthian order, acting as a support to a greatly projecting cornice, the bed-mould being carried round it, and the effect, owing to its occurrence with but little space between, being much that of an elaborately enriched dentil course. As a rule, its employment in such a position seems legitimate enough, though it must be owned that it appears more often to depend from than to support the cornice over, this being in such cases due to error of design, not only the appearance but the actuality of support being intended.

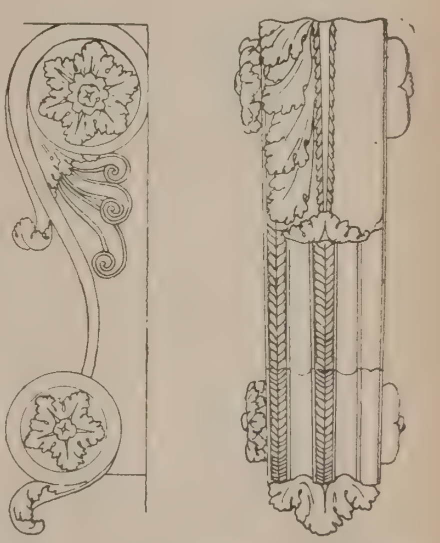
Its use as a bracket once established, however, its degradation was certain, and its employment to carry sills of niches, upon which sills rest small orders—as at the palace at Spalatro—can hardly be defended, their apparent weight-carrying power being insufficient for the task imposed.



Door Console from Charmyleion Pyli, in the Island of Kos.

(From Newton and Pullan's "Halicarnassus.")

Another detail which was eminently suited to Roman tastes, and which it was left almost entirely to the Romans to develop, was the acanthus scroll, and so long as it is found without the intermixture of natural forms, taken from either the animal or the vegetable kingdom—so long, that is, as it was entirely conventional—so long was it invariably pleasing. In fact, the scroll with which the frieze of the Maison Carrée is enriched has rarely been surpassed for richness and voluptuous beauty of design, without over-much of self-assertion, it being carved in sufficient, but not overwhelmingly powerful, relief, and being suitable to its position as a band of ornament, at a considerable height above the eye, upon a rich Corinthian building.



Door Console from the Maison Carrée at Nismes.

DESIGNING OF STEEL BRIDGES, THEORETICAL AND PRACTICAL.—XX.

IT is not until one proceeds to the investigation, step by step, of the separate stresses acting upon the individual members of all open-web girders, frames, and trusses, that one becomes both theoretically and practically acquainted with what may be appropriately termed the anatomy of articulated structures. Under this category are included bridge girders, roof trusses, and all types of similar constructions, whether horizontal, curvilinear, or polygonal in outline or elevation, which are built up of distinctly separate parts, united together at their junctions by rivets, pins, bolts, gibs, and cottars, or other species of connections. Around these points which constitute the joints or articulations, the various members are supposed to be free to move, and, in fact, do move, and also deflect to an appreciable degree under concussion produced by the impact of a heavy passing or travelling load. Another *sine quâ non* in the definition of a properly articulated structure is that each separate member is considered to suffer stress solely in the direction of its own length, and should never be exposed to stresses of a transverse character. In badly-designed and proportioned girders, the different parts are no doubt subjected to the action of transverse stresses. It may be advanced that "After all, it does not much signify," as some of these defective girders do their duty satisfactorily. We are perfectly aware of the truth of that statement, and could point to existing examples; but it is nevertheless a practice more honoured in the breach than in the observance. The danger attending the placing of parts of an articulated truss under stresses of a transverse nature, is that they become liable to distortion and deformation. It is, moreover, a matter of notoriety, and abundantly proved by the examples of the failures of girders and trusses, that deformation and distortion have invariably preceded their collapse. Even cast-iron girders, brittle as they are, deflect and give some warning of their approaching destruction, unless there should be some very serious flaw or local weakness in the material itself.

When the great variety in the forms of trusses, girders, and other examples of steelwork is considered, it might not unreasonably be supposed that any arrangements of parts or different members, provided they were solidly secured at their junctions, would in themselves constitute a truss. Such a supposition would be entirely erroneous. Every properly and scientifically-designed girder, whether of the regular curvilinear form of the bowstring, crescent, or braced arch type, has to fulfil certain conditions with respect to the number of its parts and the angles they contain. It is true that a perfect system of bracing can be constructed of any polygonal figure, whether it be regular or irregular, symmetrical or unsymmetrical, provided certain rules are adhered to. The designing and construction of trusses, which are essentially braced structures, were very imperfectly understood until architects and engineers found it necessary to altogether abandon timber for bridges and roofs of large span. Previously to this period, some very fine specimens of timber roofs had been erected, and exist to this day; but they may perhaps be regarded rather in the light of a *tour de force* than in that of a legitimate use of the most suitable material. As a proof that bridges of timber are still built, even in countries near home, we may quote the example of one put up barely a year ago in St. Petersburg, and intended to connect the quarters of the old town with the district of Vassili Ostroff. Although of considerable convenience to the inhabitants, the bridge in other respects is a failure. It interferes to so serious an extent with the navigation that vessels which were formerly in the habit of frequenting the waterway crossed by it have discontinued their visits, and make instead for the newer and more commodious harbour of Gutuyeff.

FIG. 1

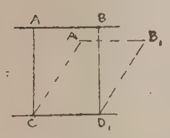

FIG. 2.

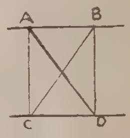
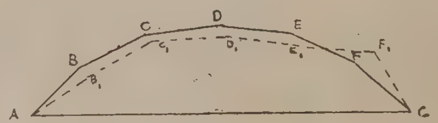


Three parts or members are the minimum number required to constitute the simplest form of truss or system of bracing, which gives us at once the triangle, the figure of all others the best adapted for the purpose, since it cannot undergo a change of form without altering the length of its sides. However complicated a truss may be—that is, however great may be its number of separate parts, it will be found that they are always so arranged as to form a series of triangles. In a trussed roof the principal or main triangle composing the rafters and tie is invariably subdivided or split up into a number of smaller or secondary systems of triangular bracing—a feature which is common to all polygonally-shaped girders, trusses, and frames. The first essential condition in every truss or system of bracing, simple or compound, is that it should be indeformable, incapable of distortion, twist, or alteration of figure without breaking. An illustration will best explain the necessity for this state of indeformability. Let A, B, C, D, in Fig. 1, represent one of the panel lengths of a bridge truss, which is purposely shown incomplete. It is evidently deformable since it can be shifted into the new position shown by the lines $A B_1 C D_1$, without altering the lengths of those lines—that is, of the sides of the figure which constitute the several parts, or members, of the truss. In order, therefore, to enable this quadrilaterally-shaped truss to fulfil this first requisite, it becomes necessary to add one or other of the braces A D or B C in Fig. 2. Both may be added, as is usually done in the central panel lengths of large bridges; but under other circumstances one only is needed, and the other is what is called a redundant member, as will be presently alluded to. This is a simple case; but without some general rule it would be impossible for the student and beginner to ascertain how many additional members were required to render any incomplete or defectively-designed compound truss indeformable. A certain number of parts are necessary, and no more. If the correct number is exceeded, some of the parts are redundant, and cause a waste of material, even if they are not productive of something worse. As a matter of absolute experience, an excess of material in the wrong place has frequently done serious injury to bridges and roofs. A skeleton elevation of a polygonally-shaped truss, A B C D E F G, is shown in Fig. 3, which is clearly deformable, as its form can be imagined as altered to that shown by the lines $A_1 B_1 C_1 D_1 E_1 F_1 G$ without altering the original lines or sides of the polygon. In Fig. 4 is introduced in the same truss a system of bracing which will prevent the possibility of the deformation in Fig. 3, or of any other form of distortion. It will be seen at once that the principle consists in dividing the original figure or primary truss into a number of secondary or subsidiary triangles, which should be as few as possible, consistent with certain practical considerations. It is not always possible to employ the minimum number of parts, which the theoretical rule lays down, for rendering a truss indeformable. A truss will, therefore, be deformable or indeformable, according to the relationship which exists between the number of the original sides or separate members, and the number of apices, corners or angular points in the primary figure. If we make S equal the number of sides in the primary truss, and A the number of apices, we shall always have for an indeformable, simple, or compound truss of any form whatever, the general equation—

$$S = (2A - 3).$$

FIG. 3



In the case of the simplest form of truss—that of a triangle, and of a triangle only—this equation has a special value of—

$$S = A.$$

Referring to Fig. 1, and applying the equation to it, we have S = 4 and A = 4, which gives a result of—

$$4 = (2 \times 4 - 3) = 5,$$

showing that the truss is clearly deformable. By the introduction of the additional brace, either A D or C B, but not both, we obtain, inserting the proper values for S and A—

$$5 = (2 \times 4 - 3) = 5,$$

which is an identity, satisfies the equation, and renders the truss indeformable.

The other example on a larger scale of a primary truss will, in Figs. 3 and 4, tend to make the subject much clearer. In Fig. 3, we have S = 7 and A = 7, so that the equation would give—

$$7 = 14 - 3 = 11.$$

The primary truss is, therefore, manifestly deformable, as shown by the dotted lines in Fig. 3. But if we apply the general equation—

$$S = (2A - 3)$$

to the same truss, systematically braced as in Fig. 4, it will be satisfied, for in that case S = 17 and A = 10, so that we equate—

$$17 = (2 \times 10 - 3) = 17.$$

It is evident that this theoretical rule, similarly to all rules of the same character, although it demonstrates very satisfactorily how to employ a sufficient number of parts in a primary truss, so as to render it indeformable, affords no information regarding the absolute smallest number that may be used. Neither does it—as, indeed, it cannot—indicate the best manner in which to arrange the system of bracing, for a truss may be braced so as to prevent all danger of deformation in a variety of ways, all of which would satisfy the general equation, but a large majority of them would be quite unsuitable in a practical point of view. The knowledge necessary to distinguish between proper and improper systems of bracing cannot be acquired solely from extraneous sources. It must depend upon the skill, the experience, and judgment of the designer, who can impart it himself to others. In Fig. 5 another system of bracing for the same truss is represented, which, while entirely unsuitable for construction, yet, as will be seen, fulfils the conditions laid down by the general equation. The value for S is 13, and for A is 8, so that we obtain the identity—

$$13 = (2 \times 8 - 3) = 13.$$

In this arrangement the number of separate parts is only thirteen instead of seventeen, as shown in Fig. 4, but, as already stated, the particular type is not adapted for practical requirements. The small angle made by the inclined struts, B O and F O with the horizontal, together with their enormously disproportioned length, would render them inadmissible in either a bridge girder or roof truss of even a fairly moderate span. It would also be inadvisable to have so many members of a truss meeting at one and the same point. The number of rivets, pins, or bolts would occasion a serious local weakness at the common point of junction. We must reserve for our next article the subject of redundant members or parts of trusses, for it must be borne in mind that all counter-braces are, in one sense, regarded as redundant members. Nevertheless, under certain conditions of a moving load, they are by no means redundant. On the contrary, they are as necessary to the safety of the structure as the principal or main braces, and must be designed with the same care and attention as the other parts of the truss or girder. Bridges have broken down for the want of proper counter-bracing. It is only comparatively recently that the subject has received the consideration which its importance deservedly calls for.

FIG. 4.

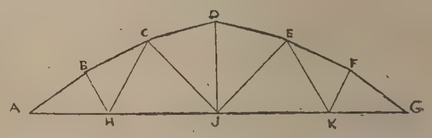


FIG. 5.

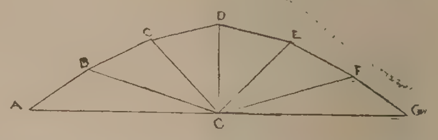

HOT-WATER HEATING IN A CHICAGO APARTMENT-HOUSE.

THE J. F. Matthews Apartment-House on California-street and Washington Boulevard, Chicago, Ill., is about 60ft. by 80ft. in size, and three stories high above the basement. Each of the three main floors is aranged in three nine-room suites, and the basement is fitted with billiard-room, laundry, storerooms, and janitor's rooms, intended to furnish in all a complete and well-equipped house for the best class of tenants. The building is heated by a hot-water apparatus installed by the Illinois Heating Company, Chicago, from whose working drawings and specifications this description has been prepared by the *Engineering Record*.

The heating system consists essentially of two vertical cast-iron heaters in the basement, with their flow and return pipes so connected that either or both may be operated or cut out at will, so that the maximum capacity can be secured in severe weather, or the service reduced and economy of fuel promoted by cutting out one heater in moderate weather, thus securing maximum efficiency of firing and fuel.

The flow-pipes from both boilers unite in a vertical pipe that rises above the attic floor and there branches into two horizontal mains that circumscribe the building, and are branched at

THE ENGINEERING RECORD

Fig. 3. ATTIC FLOOR PLAN

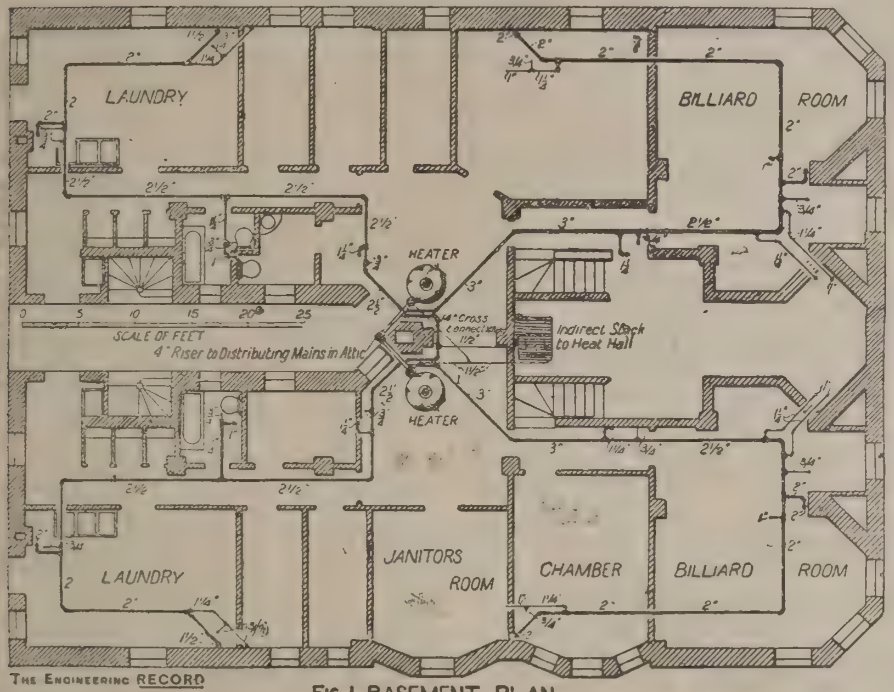

Fig. 1. BASEMENT PLAN

different points with twelve 2in. pipes and two 1½in. pipes that supply two 1½in., 1¼in., and 1in. vertical drop-pipes feeding the radiators which are disposed in vertical tiers beneath them in corresponding positions on the different floors.

These single drop-pipes, which are concealed in the partitions, also serve as return-pipes from their radiators. Each radiator discharges into it below the point whence its supply is taken; and at their bottom ends, in the basement, the pipes are connected to a belt-pipe on the ceiling that brings all the return-water back to the boilers and delivers into one or both of them as desired. Both this pipe and the attic pipe increase towards the boiler in proportion to the added number of radiators served.

All the radiation is direct, proportioned and located as shown in the plans, except one large indirect stack near the basement ceiling, which receives cold fresh outside air from the west side of the building, and delivers through a 16 by 24in. electro-bronze floor radiator into the lower hall, thus warming the whole entrance and stairway. The sectional hot-water heaters have round firepots and grates. The grates each have areas of about 9sq.ft., heating surfaces of 150sq.ft., and are each furnished with one hot-water angle thermometer, one 5in. dial altitude gauge, one ¾in. Jenkins pop safety-valve with water relief, one ¾in. Pratt and Cady check valve, one ¾in. drain cock, one ¾in. feed-cock, and are connected to the water-service and sewer system. The smokepipe is fitted with a cross-ratchet damper. The 16in. by 36in. heavy galvanised steel expansion tank is

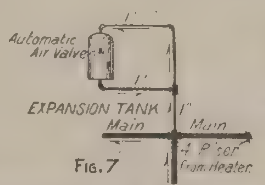

Fig. 7

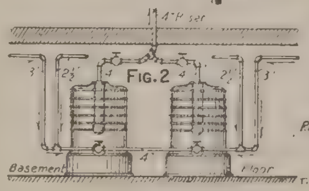

Fig. 2

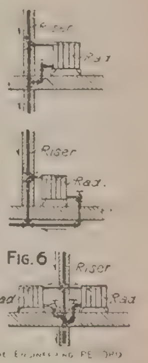

Fig. 6

connected with flow and return pipes to prevent danger of freezing. All pipe lines in the basement are supported by ring hangers securely fastened to the joist. Where pipes pass through floors the openings are fitted with old copper floorplates, and where pipes pass through walls in basement they are fitted with sleeves equal in length to the thickness of the wall, and on either side fitted with a pipe flange held in place with a set-screw. Each radiator is furnished with an old copper cherrywood wheel, quick-opening Union radiator valve, an old copper Union elbow, and an old copper air-cock with shield and key.

The direct radiation is decorated and the boilers and pipes in the basement painted black or maroon japan, two coats. The indirect stack is securely supported from the basement floor with 2in. iron-pipe columns, and is incased with matched boards and lined with red rosin paper, asbestos, and bright tin, the tinwork extending up to the face of the register. The 3,700sq.ft. of direct radiation is of the American Radiator Company's manufacture, and the 300sq.ft. of indirect radiation is of the standard pin type, made by the Standard Radiator Company, of Buffalo, N.Y.

The heating contractor guaranteed complete circulation with the temperature of water at 100°, that the apparatus should be noiseless in operation, and capable of heating all the rooms in the house to a temperature of 70° during the coldest winter weather, when the water at the boilers does not exceed 180°.

Fig. 1 is a basement plan showing location of heaters and size and position of return mains.

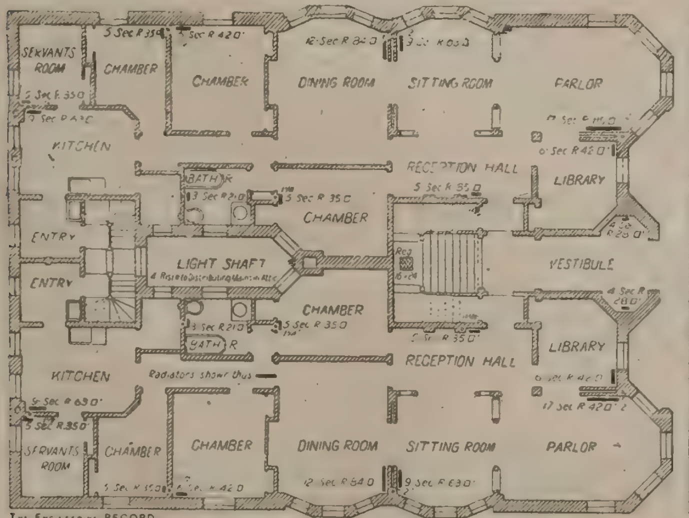

Fig. 4. THIRD FLOOR PLAN

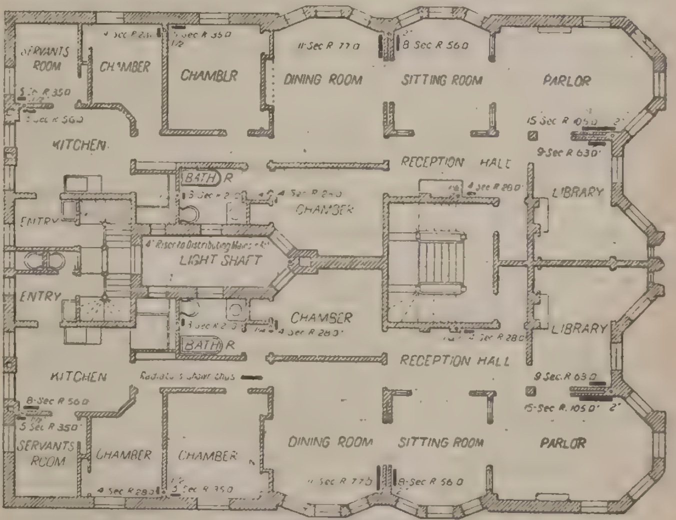

Fig. 5. SECOND FLOOR PLAN

Fig. 2 is an elevation of the two heaters, and shows the method of connecting flow and return mains.

Fig. 3 is a plan of the distribution main in the attic.

Figs. 4 and 5 show the arrangement and proportioning of radiators on the first and second floors. Those on the third floor are similar to those on the second floor.

Fig. 6 shows the different methods of connecting radiators singly and in pairs to the drop pipes, with valves on the return only, and Fig. 7 shows the connections made to insure circulation in the expansion tank.

CHIPS.

Damage to the extent of £2,000 was caused by a fire which broke out on Saturday night in the premises of Messrs. S. B. Dix and Co. at Cheltenham.

The result of the appeal that has been made to the City companies and the merchants and bankers of the City to combine in subscribing towards the celebrated Holbein picture, at Barbers' Hall, has admittedly proved very disappointing. Less than one thousand pounds have been subscribed towards the £15,000 asked for.

Although some of the larger properties offered failed to change hands, the aggregate for last week's sales at Tokenhouse-yard was fairly satisfactory, being £179,772. Messrs. Debenham, Tewson, Farmer, and Bridgewater held, on Friday, a sale of freehold ground-rents in Creechurch-lane, Leadenhall-street. Prices varying from 27 to nearly 31 years' purchase were realised, although the reversions will not fall in for upwards of 75 years.

Mr. Bruce Joy has recently executed for the Benchers of Lincoln's Inn a replica of the bust of Earl Cairns which he made some years ago for his family. The bust has been placed in the vestibule of the hall of Lincoln's Inn.

After ten years of quiet work in temporary buildings, the authorities of the Cambridge Training College for Women Teachers have been able to erect large college buildings by means of a grant from the Pfeiffer bequest and voluntary subscriptions. The new buildings will be formally opened on Saturday, October 19, by the Marquis of Ripon.

The Burns monument at Ayr, unveiled in 1891, will be completed by a bronze panel about the latter part of August, representing "The Parting of Burns and Highland Mary," the sculptor being Mr. George E. Bissell, Poughkeepsie, New York. Three sides of the monument have already been filled. The fourth panel, fronting the west, which was left for friends in the United States to complete, will therefore soon be occupied.

Kinghorn Parish Church, N.B., was opened on Saturday after entire reconstruction. The galleries have been removed, and a new roof has been put on. The building occupies the site of a pre-Reformation Church, and the old chancel-arch has been opened up and a new apse built behind it. A new west gable, tower, and entrance-door have been added. The architects are Messrs. Sydney Mitchell and Wilson, Edinburgh.

A committee of the city council of Bristol have under consideration plans prepared by the city surveyor, Mr. Yabbicom, for new meat and fish markets in Queen-street, Tower-hill, and Passage-street. The scheme, if adopted, would, after providing for the widening of the thoroughfares, provide two blocks of markets 37 per cent. larger in area than the existing ones.

Mr. W. Urquhart, the vice-chairman of the Fire Brigade Committee, laid on Monday the foundation-stone of the new fire station now in course of erection in Renfrew-road, Kennington, for the London County Council.

For the ventilation of the Balgray Girls' Industrial School, Dundee, now in course of erection, Messrs. James McLaren and Sons, architects, the latest improved form of the "Climax" direct-acting, invisible roof ventilators, and the "Climax" direct-acting, continuous-exhaust ventilators have been supplied by Messrs. Cousland and Mackay, entilating engineers, Glasgow.

M. Paul Alfred de Curzon, the eminent French landscape painter, has just died at Paris in his 75th year. Born near Poitiers, he first exhibited at the Salon in 1843, and six years later gained the highest distinction a landscape painter can obtain in the Ecole des Beaux-Arts. Among his best works are "Les Parques de Béranger," "Dante et Virgile sur le Rivage du Purgatoire," "Les Ondines," "Triptyque," "Graziella," "Le Bois de Boulogne," "Le Tasse à Sorrente," and "Les Fortifications de Paris." He also accomplished much work in lithography, etching, and pastels, including "Les Baigneuses," "La Sérénade," and "Le Tonnelier de Nuremberg."

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—J. S. Parsons.—T. W. and Co.—V. R. G.—Bellagio.—J. D. R. and Co.—S. B. (Chester).

THE ARCHITECTURAL PROFESSION IN THE NORTH OF ENGLAND.

To the Editor of the Building News.

Sir,—As one who has had an experience of twenty years in various architects' offices in the North of England, I cannot understand how an architect here could expect to win competitions in the way described by your correspondent, "An Old Subscriber."

In my experience I have been more successful in preparing competition plans in the South than in the North, and just recently I did the principal part in designing plans that were placed first in a large competition within a short distance of London, and if the competition had been in the North, I venture to say there would have been more able competitors.

As for the quantities, I cannot but think that the builder referred to by your correspondent must have got hold of a specification, not knowing which was which.

I frequently observe that architects in the North give more sketches in their quantities than those in the South. This I account for by the fact that they are taken off more by those who prepare the plans, and who are able to give better ideas of what is required than if taken off by a quantity surveyor.—I am, &c.,

Gateshead. W. S.

Lady Howard de Walden laid the foundation-stone of an enlargement in connection with Holy Trinity Church, Shoreditch, on Saturday afternoon.

The engineers of the Snowdon Railway have decided to construct it on lines similar to the latest Swiss mountain railways. The gauge will be 2ft. 7½in., and the sharpest curves will have a radius of four chains. The length of the line will be 4⅝ miles, and terminal stations will be erected at Llanberis and the summit. The locomotives are being manufactured in Winterthur, Switzerland.

Intercommunication.

QUESTIONS.

[11381.]—**Dancing Floor.**—Can any of your correspondents kindly give me particulars of the very best dancing floor that can be produced, expense being no object? Size, 40ft. by 21ft.—Philip T. Hopwood.

[11382.]—**Mastic for Wood-Block Floors.**—Can any reader say of what mastic used in laying wood-block floors is composed of, whether there are different makes with different materials, and which is the best, and how to make?—Enquirer.

[11383.]—**Fountains Abbey.**—Can any correspondent inform me whether any permission is required to measure at Fountains Abbey, and, if so, from whom? Is there any good work accessible without the use of long ladders?—Ivy.

[11384.]—**Damp Floor to Cellar.**—Can any of your numerous readers inform me of a thoroughly dry floor for a new cellar?—as the one that has been formed is not so. The subsoil outside the cellar walls (which, by the way, are built hollow work) is of a light-brown wet loam and clayey gravel, the strata immediately below this being the Oxford blue clay. The ground above the blue clay has been thoroughly drained to just below the cellar-floor level. The surface drainage does not sink below the level of the top of the blue clay. The cellar floor has been laid down in cement concrete of extra thickness, and rendered to a fine face with cement rendering. Now the trouble and singular part of it is this—viz., that in dry weather the floor becomes covered with moisture and dampness, whilst in wet weather the floor is fairly dry. There are "Rock" and other compositions in the market. Would a coating of any one of these effect a cure of the evil? It is a cellar to a large house, which is required to be used as a brushing room. The height must not be very materially diminished.—J. Feacey.

REPLIES.

[11377.]—**Water-Colours.**—I proceed to give a few hints from my own experience as to sketching from nature in water-colour, and laying on tints, &c., for the benefit of "A Sketcher." My first master was a water-colour artist of local distinction, after which I availed myself of the instructions given by the master of a school of art, whose sketches were above the average, and I took private lessons from him. But of course I had that intuitive feeling for colour which helped me much, and which has never left me. One of the first lessons I learned was to work with good materials; to use Whatman's thick rough drawing-paper damped and stretched on a drawing-frame or in the solid drawing-block, and work with good colours with sable brushes. "Atmosphere" was impressed upon me as of first importance, to secure which a general or local tint over everything was first put on. I would recommend "A Sketcher" to lay in a first tint of grey and brown, beginning with the grey at the top and working down, blending in the brown towards the foreground. Cover the white paper with this tint, except any high lights in the sky and foreground. You preserve air and space by this means. The after-tints for light and shadow ought to be put in with precision and boldness to the pencil outline, and they should be bright and pure, and flat. Take care to lay the tints to the edge of outline, and keep them clean and sharp; never retouch them, and use a full brush. Never retract, and be particularly careful to leave the edges of these tints untouched, the after-tints and detail being kept rather within. The next thing is to put in the detail on this general massing of light and shadow. Here, also, boldness and decision of touch is essential, so as to preserve the forms of the objects. Never mind raw edges: they are better than re-worked muddy edges, produced by retouching, so dear to the novice. It must be remembered that a sketch is not a finished picture. In fact, finish is often inimical to effect, and many painters regard their rough out-of-door sketches as more successful than their finished colour drawings made from them. Remember you require three washes to express your meaning: a general broad and flat tint for high lights, a middle tint, and shade. Contrast is another essential quality, and every shadow should be a true contrast to the light. Thus, blue is opposed to orange, red to green, and yellow to purple, and all contrasts are obtained on this principle of opposite colours. A shadow made by deepening the colour of the light, as, for example, the shadow of a stone building, would be tame and dull to an extreme, producing a dirty effect. Again, contrast is valuable to force the effect of colours, and to make a colour look light or cool or warm by its opposite. I wish to impress on the learner the value of a course of neutral tint drawing before commencing water-colours. My first drawings were monochromes of sepia or bistre; the system familiarises the hand with the handling of washes and tints. Colours like sepia and indigo, Indian ink and indigo, the latter for the distances. Indian ink or sepia will give every foreground tint, especially if a little of the warmer pigment be used in the details of foreground and parts in sunlight. This system is generally taught in the schools of art, and is an excellent preparation for colour sketching. A few well-selected colours (moist) are better than a large number of pigments of doubtful value. A box of 12 colours may include gamboge, raw sienna, yellow ochre, burnt sienna, crimson lake, light or Indian red, vermilion, cobalt, indigo, brown pink, Vandyke brown, Payne's grey, all these being given in some boxes. Brown madder, Prussian blue, sepia, burnt umber, and Chinese white are also useful. For stonework in sunlight, yellow ochre, warmed sometimes by a little lake or Indian red or brown pink, may be used in the strong warm parts, or a grey composed of light red and indigo for the shaded portions, the cooler blue tint prevailing. Blending the warm and cool grey tints in the first wash on a damp surface is sometimes practised with effect, and the rough texture of wall surfaces is sometimes imitated by scraping, by sponging, or sand-papering the granular surface of the rough paper. What are technically known as "dry touching" and "dragging," or "scumbling," are other processes which give the same effect, but these can only be used after some mastery has been obtained. For old stone buildings cool grey tones are most to be desired. Warm shadows are to be avoided, as they produce unpleasant contrasts with the lighter parts, and too yellow or warm tints generally give a cheesy appearance that is unpleasant.—G. H G.

Legal.

A BUILDING LINE CASE.

THE case from the City-road, London, has been confirmed on appeal (*Times*, July 17), and so it comes to this—that the long forecourts with dwarf walls and iron railings in front must remain as they are; at all events, for the present. It is true a future County Council may be persuaded to grant a license to build shops upon these useless gardens, as has been done in so many similar thoroughfares around London; but it is certain that, without this license, nothing can be done to render available this valuable freehold land. It appears that the owners of the house had begun by putting a hoarding on the dwarf wall, and against the iron railings, as an advertisement; but upon objection being made by the Council this was removed. Since then he had built a wall 11ft. high in place of the dwarf wall of some 3ft. and railings of about 5ft., and the question then arose whether that was not a building or structure beyond the building-line, and so should be removed.

The case has been fought right through, the architect's certificate that the line of the old house was the general building line of the road having first been appealed against and confirmed. Then the magistrate's ruling that this wall was "a building structure or erection" within the words of the Metropolis Management Act of 1862, and therefore illegal, as being beyond the building line, was made the subject of an appeal—first to a Divisional Court, and now to the Court of Appeal—only to be confirmed by both tribunals. The magistrate also found as a fact that the wall was intended to be used as an advertising station and as a boundary to the forecourt. The order to demolish the structure, therefore, stands good, and the owners have to pay all costs. It is rather difficult to see how they can have expected any other result. At the same time, the case is of much practical importance, as affecting the value of old property of this kind, which, having long ceased to be really residential, is more fitted for commercial purposes, for it shows that the conversion of such forecourts into shops may be made quite impossible by the action of the local authorities. **Fred. Wetherfield**, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

X. Y. Z.—Urban District Council.—Division.—Wards.—It does not seem to me clear that an election is rendered necessary. That is a point upon which the Local Government Board should be applied to for directions.

P. H. A.—Building.—City of London.—I do not know of any. But there may be general orders or by-laws, as to which it would be well to consult the Commissioners of Sewers.

LEGAL INTELLIGENCE.

Sewage Nuisance at Leyton.—Attorney General v. Walthamstow Urban District Council.—A motion was made on Friday last by the Attorney General on the relation of the Leyton Urban District Council for a sequestration order against the defendants, the Walthamstow District Council, for their disobedience to an injunction granted by the Court in 1875, restraining the Walthamstow local authority from discharging the sewage of their district into the Leyton Level Brook so as to cause a nuisance. The nuisance complained of had been a long-continued subject of complaint by the Leyton local authorities. The brook in question receives the sewage of Walthamstow, and after flowing through Leyton discharges itself into the tidal waters of the River Lea. After the injunction granted in 1875, the Walthamstow Board made a sewage farm extending over 160 or 170 acres, and sewage works. In 1884 the Leyton Board took further proceedings to enforce the injunction of 1875, and the Walthamstow Board gave an undertaking to comply therewith. Frequent complaints had been made since, but no further proceedings were taken until the present time. It appeared that the population of Walthamstow had increased from about 12,700 persons in 1875 to 24,800 in 1884, and 56,600 in 1895, and that the total sum expended on their sewage works by Walthamstow was some £112,000, of which £45,000 had been spent since 1884.—The Judge said the applicants had made out their case, and were entitled to the enforcement of their rights. He granted the order asked for, but directed the order to lie in the office until April 1, 1896, with liberty for the respondents to apply for further extension of time.—It was stated on behalf of the Walthamstow District Council that it would be at least two years before they could complete the new sewage works.

Infringement of School-Desk Patent.—Bennet v. Bruce.—In this action, in which judgement was given on July 20, in the Scottish Court of Sessions by Lord Low, James Dick Bennet, cabinet-maker, 40, Tennant-street, St Rollox, Glasgow, sought to have Alexander Bruce, joiner and builder, 37, Commercial-street, Maxwelltown, Dundee, interdicted from infringing his letters patent for improvements in schools-desks and seats, and from applying a registered design of which he is proprietor, to school-desks or seats. The respondent denied the alleged infringement. Lord Low held that there had been infringement of the patent, but not of the design, and, as regarded the former, granted interdict, but refused it as regarded the latter. The complainer was awarded expenses.

Speculative, but not High-class.—At Marylebone, John Sanders, a builder, of Lisburne-road, Hampstead, was summoned last week by Mr. William Smallpiece, the district surveyor for East Hampstead, for using mortar the ingredients of which did not conform to the requirements of the by-laws of the London County Council. The evidence in support of the summons was that the defendant was the builder of a house in the Constantine-road, Hampstead, in the erection of which he had used mortar deficient in lime to the extent of 15 degrees. For the defence it was admitted that the defendant had committed a technical breach of the by-law, but it was urged that similar mortar had been commonly used in the Metropolis for years past, and that if the prescribed amount of lime were used, the mortar would set too quickly. A witness called by the defendant stated that the mortar used was good enough for "speculative buildings," but it was not "high class." The magistrate said it was clear that the mortar was not up to the standard which the public had a right to expect. The public were absolutely at the mercy of the builders, and if they used inferior mortar it was nothing less than a fraud upon the persons who took the house. He imposed a fine of 40s., with 23s. costs.

Customs of Foremen Joiners in Southport.—At Southport County-court, on Tuesday, a foreman joiner, who sued a contractor for moneys out of pocket, and wages in lieu of notice, said some of the money disbursed was in treating a clerk of works on each visit—a well-known custom, he averred. Plaintiff added that, in the interest of his employer, he had made out false time-sheets, and had stolen windows. He denied that he was summarily dismissed for deceiving his employer, but admitted that he entered a man on the wage-sheet at 8½d. an hour, of which the man was only to get 7d., while plaintiff pocketed the difference for the loan of two planes and other tools—another well-known custom. The defendant denied all knowledge of any of these practices, personally or in the trade; and said that, on finding the irregularity in the wage-sheet, he summarily dismissed the plaintiff, who, as he had admittedly been drinking, might not remember exactly what passed. As to the charges made by the plaintiff, he warned him of their seriousness, and of the danger to himself.—His Honour (Judge Collier) held that the dismissal was warranted, and gave judgment for the defendant with costs.—Defendant said he had no vindictiveness against plaintiff, and he would forego a counter-claim for the difference between the 7d. an hour which the man actually received and the 8½d. which plaintiff obtained from him.

In re Saunders and Leadam.—The bankrupts, who had traded as merchants of foreign hardwood at 5, New London-street, under the style of Godfrey S. Saunders and Co., applied for their discharge. The receiving order was made in November upon the petition of the Comptoir National d'Escompte de Paris, and proofs amounting to £45,480 have been lodged, about £2,750 further being outstanding. The assets have realised £6,608, and £842 further is expected to be received. The Official Receiver (Mr. A. H. Wildy) opposed on statutory grounds. Mr. Registrar Linklater, in giving judgement on Monday, said it was reported that the bankrupts had continued to trade, and had contracted the whole of their indebtedness, amounting to about £48,000, with knowledge of insolvency. Saunders had previously failed, but had not profited by that experience, and now failed again. He held that the charge of trading, after knowledge of insolvency, had been substantiated, and he regarded it as a serious offence. A charge of misconduct in relation to certain trust moneys had also been made out in the case of Saunders, but displaced as to Leadam. A charge of rash and hazardous speculation had, in his (the Registrar's) judgment, fallen to the ground; but, with regard to Leadam, it appeared that he had contributed to his bankruptcy by unjustifiable extravagance in living. The discharge of Saunders would be suspended for six years, and that of Leadam for three years from the date on which the public examination was concluded.

Damages from Sewage-Farm Flooding.—Clayton v. Croydon Rural District Council.—In the Queen's Bench Division, on Friday, before Mr. Justice Grantham and a special jury, this action was tried, in which the plaintiff, a farmer, sought to recover £160 damages for injury to his crops in consequence of the overflow of a sewage farm constructed and worked by the defendants at Merton. For the defence, it was contended that the overflow was caused by excessive rain, and was therefore such as nobody could be reasonably expected to anticipate or prevent. The plaintiff quoted the printed reports of the sanitary authority's own engineers, who, since March, 1893, had called attention to the leakage of the sewers and other defects, and had suggested remedies, which the authority had been considering for two years, and were still considering. The following cases were relied on for the defendants:—"Dixon v. Metropolitan Board of Works"; "Whitehouse v. Birmingham Canal Company"; "Thomas v. Birmingham Canal Company"; Box v. Jubb"; "Nitrophosphate Company v. St. Katharine Docks Company"; "Nichols v. Marsland"; "Fletcher v. Rylands," and it was urged that the case ought not to be submitted to the jury. A verdict was, however, returned by the jury for the plaintiff for £115, for which judgment was entered, execution being stayed for a fortnight.

Covenants to Repair.—Jaquet v. Edwards.—An action was heard by Mr. Justice Wright, without a jury, last week for the recovery of some premises in Bermondsey for breach of a covenant to repair. The premises in question were a hat manufactory at 132, Long-lane, and had been granted on a repairing lease to the defendant in 1889. Previous to the execution of the lease there had been an agreement between the parties whereby the defendant agreed to accept a lease after certain repairs had been executed by the plaintiff. One of the points of the defence was that some of the repairs now alleged to be necessary were repairs that the plaintiff was liable to do under that agreement, and it was said that the execution by the plaintiff of these repairs was a condition precedent to the defendant's liability. "Neale v. Ratcliff" (15 Q.B. 916 and "Coward v. Gregory" (L.R. 7 C.P., 172) were cited in support of the contention, but Mr. Justice Wright decided against it. The defendant, besides denying that any repairs were necessary, further contended on the authority of "Skinners' Company v. Knight" (1891, 2 Q.B. 542) that the notice required by section 14 of the Conveyancing Act, 1881, duly served on him before the action, was bad on two grounds—(1), because it included among the repairs therein specified, a charge of £39 10s. for drainage which the plaintiff had been compelled to incur at the instance of the sanitary authority—a charge which had now been abandoned—and also included the repairs above alluded to, which the plaintiff ought to have done; (2) because the notice gave six weeks within which the repairs were to be done, and that time was an unreasonable one, looking at the amount of the work required; and, in addition, there being a covenant in the lease to repair upon six months' notice, that time must be taken to have been agreed upon as a reasonable time. For the plaintiff it was argued that the covenant to repair and the covenant to repair upon notice were distinct covenants, and that the Act not having required that any time should be named, the notice was not invalidated by its specifying too short a period, so long as action was not brought within a reasonable time afterwards. Neither was a notice bad merely on the ground that it included things which were not afterwards insisted on. Mr. Justice Wright found that there had been a breach of the covenant to the extent of some £5 or £6 in respect of repointing a certain wall, but not to the extent claimed; so he gave formal judgment for the plaintiff, and granted relief to the defendant on his executing the above repairs.

CHIPS.

Christ Church, Ilfracombe, has just been restored, receiled, and reseated from plans by Mr. H. W. Weir, of that town.

The commemoration of Archdeacon Denison's jubilee will take the form of the restoration of the cross in the churchyard at East Brent, the base of which has been standing for some five centuries. The work has been put in hand, and will be completed by Saturday week.

The loan exhibition at the Guildhall Art Gallery closed on Sunday evening, the number of visitors since its opening having been 262,810, and the average attendance on Sundays 1,518. The total number of those who have visited the four exhibitions organised at the Guildhall is 908,921.

Our Office Table.

Three fresh pictures have just been hung at the National Gallery. Of these, the principal one is the work by John Sell Cotman (1782—1842), "A Galliot in a Gale," recently acquired for the trustees at a sale at Christie's. It represents a vessel sailing under mainsail on a stormy sea, a town perched on rising land being seen to the right. The work is the second example in the collection by the leading spirit of the Norwich school, is numbered 1456, and is hung in Room XX. No. 1459 is a portrait group, by Gerbrant van den Eeckhout (1666-95), a Flemish artist not previously represented in the Gallery, and is hung in Room XI. It is a large work, showing four men consulting a drawing and book on a table at which they are seated. In front is a terrier. The third work, No. 1460, is "Smugglers on the Irish Coast," by Julius Cæsar Ibbotson (d. 1817), also a new name in the Gallery catalogue. A crowd of men and women are transferring casks and other contraband goods from the shore to carts.

Mr. Edgar Barclay, who exhibited three years ago in the Conduit-street galleries a number of oil-paintings representing Stonehenge from every aspect and under every condition of atmosphere and lighting, has just published a quarto volume on the remains, entitled, "Stonehenge and its Earthworks." Mr. Barclay gives an exhaustive summary of all the writers who have attempted to account for the circle of great stones on these high-lying downs, from the time of Inigo Jones to the present day. His own conclusions are thus expressed:—(1) That Stonehenge is a temple, not a tomb, though many funeral barrows are in its immediate neighbourhood; (2) that it is not pre-historic, or of the Bronze age; (3) that it is not so late as James Fergusson would have placed it—the time of the Saxon conquest; (4) that it is not, as Dr. Guest conjectured, the work of the Belgæ; (5) that the blue stones are certainly foreign, and must have been transported over sea; (6) that the work is in all probability one of those undertaken by Agricola to pacify and employ the people of Southern Britain.

The remarkable collection of objects made and utilised by the so-called "New Race," found by Professor J. E. Flinders Petre, with the assistance of Messrs. Grenfell, Price, and Duncan, along the desert edge between Ballas and Nagada, and about 30 miles north of Thebes, are now on view at University College, Gower-street. The conjecture is that the remains date from about 3,000 B.C., and that they are the work of the people who overthrew the first great civilisation of Egypt at the fall of the VI. Dynasty, and were in turn overthrown by another Dynasty rising at Thebes. The earliest remains found are Palæolithic flints from the top of the plateau, and in the gravels of the Nile plain; but there are also pieces of pottery of many shapes and primitive ornamentation, and various other objects found in the graves of the New Race. Not the remotest traces of anything approaching Egyptian civilisation—and, indeed, nothing Egyptian—has been found in their graves, and the pottery, made by hand, indicates ignorance of the potter's wheel which was in use with the earlier race. With their dead were placed many large jars containing ashes of the funeral feast, though the body was never burnt, also drinking vessels, and before the clenched hands of the deceased was a slate with malachite ground on it, and a pebble grinder, and sometimes a bag of malachite and galena in one of the hands. Many beads were found on neck, arms, wrist, fingers, and ankles. The remains excavated represent nearly 2,000 graves, and two small towns built of mud-brick. The flint implements show very fine workmanship. The pottery includes a group of jars with marks scratched on the surface, the nearest approach to writing discovered in the doings of the New Race, and there are also black incised bowls.

In connection with the 63rd annual meeting of the British Medical Association, to be held in London next week, a series of conferences on hygienic subjects will be held under the auspices of the Sanitary Institute, at the Parkes Museum, Margaret-street, W., on Tuesday, Wednesday, Thursday, and Friday next, between the hours of 4.30 and 6 p.m. On Tuesday the subject of the positions of medical officers of health in regard to the administration and working of the Infectious Diseases Notification Act will be introduced by Sir Thomas Crawford. On Wednesday Professor A. Wynter Blyth will give a demonstration of the teaching of hygiene, as illustrated by the Parkes Museum. Thursday's meeting will be devoted to a discussion on the pollution of streams, a subject to be brought forward by Dr. George Reid, medical officer of health to the Staffordshire county council; and at the closing meeting on Friday, Aug. 2nd, Professor Percy Frankland will lecture on the "Bacterial Purification of Water."

The Birmingham Architectural Association second annual sketching excursion is to be held at Ludlow and the neighbourhood on the 3rd, 4th, 5th, and 6th of next month. The number is to be limited to twenty, and photographers are requested to bring their cameras. Messrs. Charles E. Bateman and Herbert T. Buckland are the hon. secretaries. The Feathers Hotel, Ludlow, will be made the headquarters, and the various excursions from Ludlow (with the exception of the visit to Richard's Castle on Sunday) will be made in a brake. On Saturday, Whitton Court, Burford, and Tenbury will be visited. It is proposed that Sunday should be devoted to Ludlow and the vicinity. A walk of about three miles takes one to Richard's Castle, where an old church, with detached bell tower, and a new church, by R. Norman Shaw, R.A., are to be seen. On Monday, the party will drive to Stokesay Castle. The church contains some Jacobean panelling and pews. The Rev. J. D. La Touche has kindly promised to exhibit some ancient drawings and other objects of interest (bearing on the history of the castle) which he has collected. On the return journey, Bromfield Church will be visited. It is proposed on Tuesday to leave by train for Church Stretton. Plaish Hall, a quadrangular Elizabethan stone mansion of much interest, will be visited. From here it is proposed to go on to Church Preen, a fine house by R. Norman Shaw, R.A., and an old private chapel. Hughley, about two miles from here, will be taken on the way to Presthope Station for the journey home. The church is a good example of Late Decorated work, containing a good rood screen and half-timbered bell-turret.

Some time since it was stated that the old Rolls Chapel in Chancery-lane was to be transformed into a museum, and thus made the connecting link in the chain of buildings forming the old and new Record Offices. The necessary authority for stopping the services and generally preparing the way for the alteration had been granted, but even now the services are being continued, though the new Record Office, which faces Chancery-lane, is almost completed, and quite hides the ancient chapel from public view. The services will be stopped next month, and the chapel will then be placed in the hands of the builders, who, while they have to retain as far as possible the historic portions of the building, have several alterations to make in order that the structure shall become perfectly proof against fire, for its walls will contain some of the most valuable documents that the nation possesses, including autograph letters of our leading statesmen, papal bulls of great antiquity, and, above all, Doomsday Book. The chapel will be so inclosed by the outer walls of the new Record Office that it will be necessary to provide a top light, and this will necessitate several extensive alterations, while the Rolls House, formerly the residence of the Master of the Rolls, is to be swept away, in order to make room for the wing of the new building.

The annual meeting of the general committee of the Palestine Exploration Fund was held at 24, Hanover-square, on Tuesday. Mr. James Glaisher, F.R.S., occupied the chair. The report of the year's work includes an account of the excavations at Jerusalem, which have resulted in the discovery of an ancient wall running south of the present city wall down towards the eastern valley, where, at a point south of the Pool of Siloam, it turns towards the north. In this wall several towers and two gateways of great interest were found. Herr Baurath von Schick also reports the discovery of a stair and postern in the old north wall of Jerusalem, between Damascus Gate and the north-western corner of the city. Another discovery of importance is that of a Latin inscription of the period of Trajan, built into the wall of Neby Daûd. In the spring of the year Dr. Bliss, who is in charge of the work of the fund, made a journey to the country of Moab, visiting Madeba, Kerak, and other places of historical interest, in the course of which he discovered remains of an ancient Roman fort and a Roman town, which do not appear to have been previously observed.

On Friday last the annual exhibition of drawings, needlework, and other handwork executed by scholars and pupil teachers attending the London board schools was opened at the Hugh Myddelton School, Clerkenwell. Work has been sent by six classes of deaf children and 26 special classes of physically and mentally defective children; 175 schools are represented by needlework exhibits, 55 by kindergarten work, 150 by laundry work, 52 by various occupations, 100 by drawings and designs, 18 by clay models; and there are 53 centres showing woodwork, and eight evening continuation schools a variety of articles. Many of the studies in light and shade are particularly well done, as are also the outlines from plants, casts, and models. There are some artistic designs in coloured paper, a subject which is taught to give dexterity of hand, to quicken the colour sense, to cultivate the sense of taste and design, and a better appreciation of form. The clay models, which include some portrait medallions, deserve praise, and there are many highly-finished and accurate specimens of woodwork.

The Canadian Government have given fair trials during the past few years to the systems of executing works of engineering and building carried out by day-labour or by contractors, with the result that public opinion in the Dominion is in favour of letting the work to contractors. The town council of Toronto are, however, trying a fresh experiment as their own contractors for the completion of the municipal buildings in that city, which will be watched with interest. The municipal buildings were begun under contract, but had only reached some 20ft. above the ground level, when the contractor (Captain Neelon) was dismissed in July, 1892. Owing to difficulties in obtaining satisfactory tenders for the completion of the works, it was decided to proceed with them by day-labour. In the mean time, the late contractor is seeking compensation in the law-courts, basing his claim on the allegation that he was dismissed owing to the bad faith of the architect, Mr. Lennox.

"The Hospital" refers to the new ailment said to have been produced on rather an extensive scale, as a result of the action of the prolonged dry weather on the wood pavements of the London streets. The symptoms, which are very distressing, manifest themselves chiefly in the mucous membrane of the nose. The membrane becomes inflamed and thickened, the blood-vessels are turgid, and on very slight provocation there is bleeding to a considerable amount. The affection is said to be due to the millions of small particles of straw and other *débris* that lie in the wake of the vast horse traffic which from morn till midnight congests the leading London thoroughfares. Last year the same, or a similar, ailment was complained of, and certain steps were then taken by the central and local authorities with the object of mitigating the danger. Those steps consisted almost entirely in flushing the principal thoroughfares well with plain water once or twice a day, and in adding to the water a percentage of Condy's fluid for those particular localities where the street debris seemed to be most offensive and dangerous. No remedy in our opinion will ever prove effectual. The wood pavements are dangerous to health in dry weather, and damaging to clothes and house fronts in wet.

The late James Renwick, of New York, who was a rich man for an architect, left to the Metropolitan Museum of Art in that city a collection of pictures which he had been many years in forming, and which is said to contain some good examples of Italian masters of the first rank of the Cinque Cento period, besides a number of pictures by painters of the same school, but of the second rank—such as Bronzino, Carlo Dolce, and others less known. Under his will, the pictures are to kept together in a room by themselves, and designated by name as the Renwick Collection, in the same way that the Wolfe Collection of modern French pictures is shown in the same museum, which, hitherto, has been exceptionally poor in works of the Italian schools of the 16th century. A considerable portion of the collection just bequeathed originally belonged to the late William H. Aspinall, whose eldest daughter married Mr. Renwick.

◆

A memorial bust of the late William Alexander, LL.D., of Aberdeen, the author of "Johnny Gibb, of Gushetneuk," has just been executed for subscribers for erection at Aberdeen. Mr. Pittendreigh Macgillivray, of Edinburgh, is the sculptor.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2117.

FRIDAY, AUGUST 2, 1895.

SALISBURY SPIRE.

THE report of Sir Arthur Blomfield, A.R.A., on the critical condition of the western turrets and spire of Salisbury Cathedral, which we published last week, will be received with some anxiety by all admirers of that graceful and unsurpassed structure. For some years past attention has been bestowed upon the question of the condition and stability of this structure, poised so beautifully and elegantly over the crossing of one of the finest Early English cathedral churches of our land. Not many years ago —in 1875, we believe—the late Sir Gilbert Scott was engaged in strengthening the tower and spire, which was done by a system of iron ties, devised by Mr. Shields, C.E. We have no doubt that eminent engineer succeeded in temporarily securing the spire, and in preventing any further deflection from the vertical; but whether the presence of so much ironwork in the stone structure was judicious we very much question. In his report Sir Arthur Blomfield, in speaking of various adverse agencies which have been gradually at work, alludes to the "numerous iron bands, rods, and ties which have been introduced from time to time, many of them in the most injudicious manner." The gradual declination of the spire, which had been noticed, we believe, in Wren's time, has been the cause of many efforts and tinkerings. Several methods had been devised before Sir Gilbert Scott took the structure in hand, and Price, in a work published in 1750, describes some of them. We believe, indeed, that the great architect of St. Paul's was engaged by the Dean and Chapter of his day to do something to the spire, and that he introduced an internal framework or scaffolding for the purpose of checking any further deflection. We know that, at Chichester Cathedral, Wren (on the authority of Elmes) constructed a pendulum stage in the upper part of the old spire to counteract the south-westerly gales which had forced it out of the perpendicular. From the finial stone was suspended a balk of timber 80ft. long, loaded with iron. At the bottom two oak floors a trifle less than the interior masonry were suspended, and when the wind blew the spire out of the vertical, the pendulous floors touched the lee side of the spire, and tended to restore the equilibrium. The failure of this spire owing to the instability of the piers ought to be a warning to all custodians of our great churches having central towers. The spire of Salisbury is stated to be 404ft. high from the pavement; its thickness at the bottom is only 9in., diminishing to 7in. at the top. The necessity of lightness for a spire of this height is a sufficient reason for reducing the spire walls to the least thickness compatible with safety. Probably, in these days, if we had to erect such a spire, a light iron-framework to support the shell of stone might be used, as was done in the re-erection of the spire to St. Stephen's Church, Vienna.

The unique design and beauty of the Salisbury spire can only be appreciated by those who have seen it from all points of view—both elevationally, in front of one side, of the tower, and diagonally. With the exception of the beautiful spire, with its clusters of pinnacles and turrets, of St. Mary-the-Virgin, Oxford, very few structures can be compared with it. St. Michael's, Coventry, can show a very elegant arrangement at the springing; but the beauty of Salisbury is unquestionably its double tier of turrets at the angles, the upper tier being set within the lower anglewise, thus giving a pleasing contour to the base of spire, especially when seen in the diagonal view. Besides external design, the advantage derived from these turrets at the corners in a mechanical sense is important. The thrust of the spire, which, as Sir Arthur Blomfield says, is great, and is "continually active," is met and neutralised to a large extent by the weight and mass of the angle-turrets, which tend to divert the lateral thrust, and to verticalise its direction in the same manner as a pinnacle does which receives a flying buttress. The report says, truly, "Nothing can be done to lessen or modify this last element of danger (the thrust), but it is imperative to render the angle-turrets, which receive so much of it, as sound and strong as they can be made." For this purpose "small repairs or patching" are pronounced not only useless but dangerous, and, the report says, the work called for is "not one of restoration, but of repair," which should be complete and thorough. It is recommended to deal with the north-west turret first, to be followed by the repair of the corresponding one on the south side. Care will have to be exercised in the removal of any of the stonework, so that no great lightening of the weight of the turrets should be attempted. Theoretically, the object should be to bring down the weight of the turrets within the angles of the tower, and this is generally accomplished by corbelling the angles of the tower inside to receive the weight of the splayed sides of the spire across the angles—*i.e.*, what is technically known as constructing "squinches," or a series of arches across the inside angles to receive the alternate sides of the octagon spire. By this device the weight of the spire is brought down and distributed over the tower walls. But there may be practical difficulties in the way of lowering the weight, and, further, it would be obviously undesirable to increase the load on the existing central piers, which by some authorities are supposed never to have been intended to carry a spire, but only the tower.

In any repairs, the existing ironwork will have to be cautiously dealt with. Iron bands, ties, and rods have been introduced from time to time, and to these must be attributed much of the split and fractured stonework. We believe that most of the damage to the spire and the fractures of the turrets is due to the tampering with the stonework when these iron bands and ties were put in. They must also have become much corroded by age. As the report informs us, attempts have been made to protect the iron with lead; but these have failed in many cases, rendering the iron more exposed to the wet and corrosion. At the bases of many spires, or inserted within the masonry of the tower at the springing of spire, bands of iron or chains are introduced to prevent the thrust, and these bands have been sometimes used at intervals in building the spire. Unless these are properly imbedded in the masonry and made secure against the intrusion of air and moisture, they are subject to corrosion, and are more prejudicial than useful as ties. The stonework becomes fractured by the oxidation of the iron, or frost enters, which also does incalculable injury. The care and maintenance of our great towers and spires is a duty which requires considerable care and architectural appreciation. No other portion of our historic edifices needs greater skill or caution. The steeples of many of our finest churches, including that of St. Mary's, Oxford, have suffered from bungling "restorations" and repairs, where portions have been rebuilt, turrets taken down and restored in the worst possible taste, regardless of the original detail, and even stucco and cement substituted for stone. For instance, at Ely, Wyatt substituted the then newly-inverted Roman cement for the lantern and great part of the west front, and there are records of other substitutions and disfigurements to our cathedrals made by Wyatt, Blore, and others, who appear to have thought little of taking down and substituting for the old, poor copies, or modern ideas of stone masonry, devoid of all the spirit and feeling of the original work. It would have been far more cautious if our tower and spire "restorers" and mutilators had paid more attention to the root of the mischief, and instead of tinkering at the summit, had made sure of the foundations, and strengthened the supporting piers of these structures. In many of our cathedrals the central piers have been found defective and weak, much too weak to bear the weight of a spire, which was generally a later addition.

* * *

RAILINGS, FENCES, AND GATES.

A RECENT law case, relating to property in the City-road, has drawn attention to what is and what is not permissible in the matter of London street fences. A dwarf garden wall and railing had been removed, and a solid brick wall 11ft. high substituted. The magistrate ruled that this was a "building structure or erection" in the legal sense of the term, and as it was beyond the building line of the houses, he condemned it. His decision was confirmed on appeal. But the facts were somewhat peculiar. They do not justify the inference that whoever has railings must have railings still, for the wall went 2ft. higher than the ironwork which it superseded; and, moreover, the magistrate found, as a matter of fact, that it was meant to be used for an advertising station. This case, therefore, does not show us what would befall the man who simply took away his railings and built himself a boundary wall of moderate height, and still less what would happen if he put up some other kind of close, or nearly close, fence instead of his open one.

The objection to close fences in towns, unless they are kept very low, is that they hinder the circulation of air. But the one-story appendages which, in the long-run, are built over so many London gardens, hinder it much more, and yet their number is constantly being increased. The strips of ground in front of a terrace grow dingier and dingier, the rents fall, the class of tenants who once occupied them move further out, and then, if permission can be obtained, the proprietor's only idea seems to be to bring out shops to the pavement line. Where it pays, no doubt, this will continue to be attempted. But it does not always pay, and then it might be worth while to consider other ways of making such unattractive property more popular. Look, for example, at the Euston and Pentonville roads. Measured across from front to front, they are of admirable width. For many people, who must live in-town, they are conveniently situated, and yet how depressing it would be to reside there. With such an outlook, on grimy gardens, box-like houses, and soot-covered trees, even Mark Tapley himself could hardly have kept up his jollity. The shops that have been brought forward here and there do not seem to prosper much, which is probably the reason that there are no more of them. But something could surely be done, even in a case like this. If a dozen gardens, here and there, were thrown into one, the trees thinned out, so as only to leave two or three of the best ones, and the open space planted with a succession of the flowers (numerous enough when sought for) which will really flourish in spite of smoke, half the repellent look of the place would be gone. A road, of course, would have to be formed between the houses and the flower-beds, and the latter inclosed so as not to shut out the view. The buidings might, at the same time, have a little outward beauty bestowed on them, and they would once more become, in the dialect of the auctioneer, "desirable residences."

This brings us back to the nature of the inclosure. It is too hastily assumed that iron railings are essential because of the difficulty of climbing them. But anybody who really wants to get over a fence, looks out for an easy point, and he seldom fails to find one. Either at the gate, or at the ends, where there is a pier or a junction with some other fence, there is pretty sure to be a satisfactory foothold, and then what is the use of all the difficulties that have been put in the way of climbing at intermediate points? When this is once realised, it becomes clear that many other materials are quite as suitable as metal. Open work in terracotta, or even in brick, combinations of brick and stone, brick and wrought iron, or wrought iron and concrete, are all available, and any of them may be made to look incomparably more cheerful than the ordinary cast-iron bar with an "ornamental" head on the top of it. They must be reasonably troublesome to surmount. We do not advocate anything over which the street rough can vault, pull up his handful of flowers, and vault back again. But there is reason to hope that the street rough of this type is growing scarcer. Even he may be educated to some extent by trusting him, and the ordinary passenger, of whatever rank, would soon learn to protect, instead of to injure, whatever was designed to make ugly places brighter.

In the country a wider range is possible. Low quickset hedges are cheap and pleasant-looking, but they do not keep out dogs. They are liable to be thinned near the base by the first stray goat that takes a fancy to them, and, moreover, they encourage the precise class of insects which do most harm to rose-trees. Holly hedges will keep out both dogs and cats, but it takes years to grow them. Yew hedges grow still more slowly, and the giants which the gardener sometimes tried to clip out of them, in the "topiary work" of two centuries ago, were apt, as Pope remarks, to be rather stunted. All hedges harbour snails, and these, with a man who grows flowers of any rarity, is reason enough for avoiding them. Rubble walls built without mortar do the same thing, but they offer some compensation in furnishing places for many interesting plants. But in some parts of Cornwall they have a system which retains their good and gets rid of their evil. The walls are built with mortar, and the coping is made with long, sharp-pointed stones set on end. These are not merely put *on* the top horizontal course, as is the fashion elsewhere: they run down below it into the wall here and there for a foot or more, and are securely bonded in. At irregular intervals one of them is omitted, and this omission produces a kind of rough square box, without a lid, amongst the coping stones. This box, which may be as big as a large flower-pot, has only to be filled with earth, and it then forms a place in which anything will flourish which affects that sort of position. Succulent plants do well there, and the wall-tops in summer are as gay as the garden borders elsewhere.

In Norfolk reed fences are not uncommon. They are less frail than might be supposed, for round the Norfolk Broads the reeds grow long and stout. A light wooden framework serves to stiffen them, and though a foot, or even a fist, can easily be thrust through them, they do sometimes serve to keep out, or even to keep in, cattle. It makes one think that cows and horses must have a kind of conscience—a rudimentary sense of right and wrong—since they could walk through these fences without the smallest effort, if they did not feel it to be improper. Split oak fences last long and answer well. The boards are thin, but they are supported at top and bottom by triangular rails. Sometimes there is a capping in addition; but this is a doubtful improvement. It certainly adds nothing to the appearance; boards cut alternately short and long, after the manner of battlements, look much better. If any dressing is given to woodwork of this class, Stockholm tar is about the least objectionable. Paint and stains are an abomination on it. An old red-brick wall, when the bricks are worn by age and overgrown here and there by climbing plants, stonecrop, and similar things, forms a picturesque and interesting boundary. What with the wild bees which burrow in its mortar, and the still brighter winged insects which watch their movements in the hope of plundering their nests, there is always something going on there, at least in sunny weather. Walls of stock brick rarely gain any charm from time. Their originally ugly tint grows uglier, and nothing loves them or takes to them. Open fences in which posts and rails are crossed by light spars arranged lozenge-wise look well in small quantities. They make, for instance, a good inclosure to a churchyard; but their pattern is too pronounced to bear much repetition. This is where amateurs go wrong in ordering goods from illustrated catalogues. They pick out what strikes them as prettiest when only a yard or so is shown in the sketch; but it does not occur to them that 50 yards of it—not to say 500—will be more than mortals can bear.

A good fence is often spoilt by a vulgar gate. For this those laggards in the race for improvement, the "ornamental" ironfounders, are commonly to blame. Their gates are as bad as their grates, and sometimes even worse. It is best to keep quite clear of them, and where an iron gate is indispensable, to design a simple wrought one. For wooden ones, ash is nearly as good as oak, and much cheaper. Yet a wholesale manufacturer of gates stated not long ago that he had never made an ash gate in his life, and was sure (because he had never tried) that they would not last. This is the sort of groove into which the mechanical repeater of stock patterns naturally gets. He learns nothing and forgets nothing, and nothing can be taught him. The "ornamental" gate of the villa garden is usually badly framed, and nearly always badly designed. Very often it has no bracing at all, and if it has, the lower end of the brace, instead of being tenoned into the heelpost, frequently rests on the bottom bar. At other times one sees it framed like a roof or a quarter partition—that is, as if it were supported at both ends, and not merely at one. But its mechanical necessities are easily mastered. Its possibilities as to architectural design are varied enough. Here manufacturers' pattern-books are useful as a warning, for they illustrate nearly all the faults into which a beginner is likely to fall. We should advise the student, therefore, to preserve them carefully, and to consult them with the same intention with which orthodox Mohammedans are said to ask the advice of their wives—that, namely, of doing the exact opposite of whatever they recommend.

LIGHT IN TOWN BUILDINGS.

THE extent to which the London Building Act has restricted building in the Metropolis, or, rather, restrained the free hand of the architect, especially in the more crowded parts, raises the question of the means of lighting our many-storied buildings and warehouses in all close-packed neighbourhoods. At the best of times our City offices and warehouses have suffered from a want of light, and all kinds of devices and expedients have been called into requisition to meet the difficulty, such as lens-lights in the pavement and areas, reflecting surfaces of white glazed bricks, silvered reflectors, light areas, &c. Yet still the difficulty increases year by year with the erection of loftier buildings by the covering of larger areas of ground and by other causes. The London atmosphere gets, if anything, thicker and denser with the rapid increase of the number of coal fires, and to all these causes we must add the restricting provisions of the new Building Act, which, by insisting on a certain angle for light, compels owners to raise the height of the remaining portion of their premises. And another section, the setting back of building lines, operates also in the same direction. As light, imponderable an agency as it is, can only penetrate in two directions—from above vertically downwards, and laterally at a certain limited angle to the sides of a building, or in a street building only through two sides, front and back—it follows that a street building can obtain light only in two ways, either directly through the roof by means of skylights, or in a slanting direction through the windows of front and back. These are the only possible ways it can be admitted. From which it will be seen that the architect's power is restricted very much. He can only obtain light through skylights when he has a top floor to deal with, or only a ground-floor story with nothing over it; but for all intermediate floors top light cannot be used. For all these intermediate stories, then, he can only get light through vertical windows, and these are to a large extent obstructed by adjacent buildings and other causes. He can, it is true, make his window openings large and place them high, so as to get all the light he can; but, as a rule, a large window is only practically available for a part of its height—the upper portion—as lateral obstructions often render their lower areas almost useless. In fact, the craze for large windows and plate-glass has not solved the problem of lighting in town streets. Very few rays of light can enter a window horizontally in the lower stories of a street house; in fact, it has been generally recognised by all competent observers that below an angle of forty-five degrees with the horizon the light from the sky is practically *nil*, and this limit has therefore been generally accepted, though repudiated by the Bench as a test of sufficiency of the amount of light. The idea of the angle of 45° arose, no doubt, from the Building Act Amendment Act, 1862, which determines the width of the street by the height of the houses; but for all that, it is a useful and reasonable test of sufficiency of light, if the angle be taken from the zenith, and we believe any court would consider such an angle of light sufficient. Taking it as some measure of adequacy, we can say that all buildings in streets whose width is equal to their height, or nearly so, are well lighted in front; but such a happy condition by no means exists in many of the London streets. In a large number of them, the width between the houses is not more than half the height to the parapets, which practically means that only the upper half of the houses on either side are sufficiently lighted, the lower half being in comparative gloom during the greater portion of the day. The direction of a street has, of course, a little to do with the light, and the northern sides of streets are necessarily worse off than their southern sides. Practically, however, in this northern climate, where the sun is seldom seen during the winter months, the diffused light from the sky is all we depend on, and therefore the luminous sky-area is the main source of light to our windows. To obtain as much of this sky-area through our windows as we can is what the architect desires. How to calculate the area of light by means of squares is laid down in treatises on light, and Professor Banister Fletcher's work on the subject shows, by diagrams, an excellent means of calculating the amount of light each window receives, and the way of estimating the amount of obscuration resulting from buildings near. There is also a certain angle on each side of a window within which light may come. How to secure this light is the question for the architect to consider. Building legislation has done little for him; in fact, the London Building Act, 1894, only provides for a minimum of light under certain conditions, and has in its 41st section laid down an angle (63½°) with the horizontal line which is quite inadequate for domestic buildings and offices. This rule only applies to the space at the rear of domestic buildings abutting upon streets laid out after the commencement of the Act. Another section provides a space in the rear of habitable basements of not less than 100sq.ft., and the 45th makes it necessary that every window of a habitable room opening into an inclosed court shall have a certain space in front of it equal to half the height from the sill of such window to the top of the court. This last rule, it will be seen, is equivalent to the angle made by the diagonal of a double square, or is equal to the statutory angle of 63½° with the horizontal, so that the real angle of light measured from the zenith would be only the complement, or 26½°. The practical effect of this rule is that no window lighted from an inclosed court is to be placed lower than a certain distance from the top.

These are the ordinary means of obtaining light in the architect's hands. If internal courts are to be of any use, they must be made large enough to secure the necessary angle of light to the lowermost window, in which case the width of every inclosed court must be equal to half its height. Thus a building 60ft. high must have a court nearly 30ft. in width. In many of the large blocks of offices in the City and Victoria-street the courts are very contracted, and the light received through the lower windows so small in amount that the offices require gas or artificial light all day. Here and there reflectors are fixed below the windows to reflect the top light through them; but those remedial measures are, at the best, subterfuges, and beg the real question. What other constructive methods are open to us? One principle must be acknowledged—namely, that top light directly admitted is worth all the light that can be obtained laterally through windows, and if we can admit this top light to every intermediate story of a lofty building the problem is solved. The plan we are about to propose will no doubt be objected to by those who are anxious to make all their floors of equal area, so as to utilise every foot of space they can, even at the risk of having gloomy rooms. The tenants and the occupants, however, of our large city buildings have an interest in the question quite as much as the owner; the public have a voice in all that affects the well-being and health of those engaged in mercantile business and in city offices; and those in whom the sanitary laws are vested have the obligation imposed on them of securing by the best means in their power the attainment of an object so essential.

The effect of the statutory diagonal line for the regulation of lofty buildings in the rear is to make a series of offsets backwards from the vertical to a sloped line, as shown by the diagrams in the Amendments of the L.C.C., embodied in the new Act. The principle we propose is to utilise as far as possible the offsets for the purpose of giving light to the intermediate stories. The setback of each story within the lower to be utilised to form a series of glass roofs or skylights, which, if made flat, and covered with Hayward's semi-prism lens-lights, might form a series of balconies. Or these top lights might be applied only to the lower and darker stories. And, of course, the same principle of sets-off may be adopted to the front of a building in a lesser degree; thus the façade would form a succession of stories each set back within the lower one, or the lower stairs only, each flat forming a top light and a balcony. Architectural variety would be introduced of a kind impossible with a vertical front. Constructionally, each wall thus set back over the ceiling of the room below would be carried by an iron girder, the ends resting on the party-walls. This method of raking back the rear walls of town houses and warehouses has been followed in several City buildings, but we are not aware that the flats or roofs have been made useful for the admission of top light in the way suggested. The plan deserves at least a trial. Vertical, and therefore the most valuable, light is obtained over the front of every story, which it would be easy by refracting semi-prisms to direct into a room of considerable depth. The principle of catching the vertical light, and of then reflecting it, is one deserving of attention. How far it would be possible to introduce projecting lens lights over the upper portions of ordinary windows we cannot say, but in narrow streets and courts we think the experiment worth a trial. We know, for instance, how, by the use of these means, a narrow pavement of lens lights can be made to illuminate the whole interior of the basement, restaurants, and Turkish baths below the street level. What can be done in basements ought to be more easily accomplished in the lighting of upper stories, where the light is less obscured and stronger. The ordinary methods of obtaining light by courts, and by borrowing through other rooms, are at present very insufficient in our towns, owing to the increased height of adjoining premises and the very limited area of the courts. Under the old law there has been nothing, excepting the law of easements (which is applicable only to a few buildings), to prevent one building owner raising his premises to such a height as to materially darken the windows of all rooms and offices in its vicinity. Submission to or acquiescence in such interruption of lights is sufficient to establish the right of such interference.

And it is worth notice in this connection that the general effect of building regulations like those of the new Act, and also of a right to the access of light by the Prescription Act, or by prescription at common law, is to make our town buildings conform more and more to a sloped or diagonal line in their section, such as we have noticed, by setting back the rear walls of buildings. The back walls and inclosing walls of courts will have to be more and more sloped back, to satisfy dominant owners and the local authorities. An inclosed court will thus assume the shape of a truncated pyramid, with its larger end uppermost—the only natural form of well for admitting light and air to the backs of buildings. The existence of "ancient lights" in so many of our old buildings which have been exposed by street improvements and rebuilding necessitates the reconstruction of the new buildings on this plan, and as the tendency to erect high buildings increases, so will the necessity arise of increasing the angle of light as measured from the zenith. So that out of evil good will come by the maintenance of those statutory rights of light which every building owner is supposed to have. The effect, indeed, of these rights will either be to increase the angle or to limit the height of buildings.

MR. ALMA TADEMA ON ART TRAINING.

IN the lecture theatre at South Kensington, Mr. L. Alma Tadema, R.A., has distributed the medals and prizes gained by the students of the National Art Training School in the sessions of 1893-94. The holders of the travelling scholarships were Miss Lilian Simpson, with the gold medal; Mr. George Scott, with the silver medal; and Mr. William B. Dalton, with the bronze medal. The report, read by Mr. J. C. L. Sparkes, the principal, stated that more than 27,000 students have passed their apprenticeship in art in these schools.

Mr. Alma Tadema, addressing the students, observed:—Art teaching is a field in which I have had some experience, for I have been a frequent visitor to the Royal Academy schools for the last 20 years. True, my work there was confined to teaching drawing and painting from the life model, but that is the highest in art, by which all the other branches are guided. Did not the Greek art, the highest of all, emanate principally, if not completely, from the study of the human figure? The human figure contains the completest curves and balances in lines that exist, and is consequently the best guide for all art, and, therefore, it is a great advantage for an art teacher to know the human figure as completely as possible. Of course, knowledge alone is not art; but, then, art without knowledge is incomplete and unsatisfactory. I should like to insist on the word "traditions," for art is not spontaneous. Art is not so much the outcome of an individual brain as it is the continuity of experiences which, concentrated in one specially gifted brain, produces those incomparable artists which are the crowning features of their time and country. Art is, with literature and music, the flower of civilisation, and, like civilisation, it is a development of what was done before. The Egyptian and Babylonian art shows the origin of the Greek forms as developed under new conditions. The Roman art was the outcome of the Greek, and the decayed trunk being grafted with Oriental experience produced Byzantine art. The Norman art was believed by their architects to be the continuation of Roman architecture, as it was the dream of Charlemagne and later German Emperors to reconstruct the German Empire, until, with the new religion, came the neglect of old civilisation. The fresh blood and the new contact with the Orient produced the Mediæval art, the beautiful northern flower that gave us our cathedrals. Little by little things forgotten were reinvented, and antiquity asserted itself once more, this time grafted on the Mediæval art, and our modern times begin. To speak of days near to us, we know that Constable and Turner are the fathers of modern French landscape painting; and in 1870 Daubigny, the French painter, said to me, "Without those great men we should not exist." Géricault, the father of Romanticism in France, had studied in England the art of the Reynolds, and the Gainsboroughs, who themselves had derived much from Van Dyke, as the last words of Gainsborough prove they believed themselves. Therefore, go on in study, in order that you may know much of what has been done, in order that you may be able to teach the real art, which is tradition, refreshed by modern feeling and temperament, and the world will gain and you will gain the world's gratitude. I insist on this because I see all around us a kind of painting produced and praised as the highest aim of art where one cannot distinguish an apple-tree from a pear-tree, an Ionian cap from a Corinthian—a world of mist, a regular bubble-and-squeak, which somehow does not satisfy me. I have heard a youngster say that he was saved by the visit he had paid to the painters at St. Ives, as now he painted the mast of a ship with horizontal touches, and not, as everybody else had always done, with a stroke perpendicular, according to the formation of the wood. Surely art is higher than painting with points or lines, or trying to imitate Berlin woolwork, because nobody has ever painted in that way before? And teaching must go deeper into the study of the human figure than time studies can teach. But you are here in a better *milieu*, for serious work is still done in this school. The great work of South Kensington is its museum and its teaching of what is now generally called the minor arts. At the Paris International Exhibition of 1878 there was an English house which took the French quite by storm, and left a decided mark on their production afterwards. The influence of the minor arts is, perhaps, greater than the one exercised by pictures and sculpture and architecture, because it goes deeper into the daily life of the people. The weavings of, and prints on, cloths, carpets, hangings, and wall decorations surround us every moment of our lives, and we form our standard of judgment in art matters very much from them. When Whistler painted the whole of his dining-room canary yellow, and had hangings and carpets and furniture to match, the yellow in which he moved must have had a great

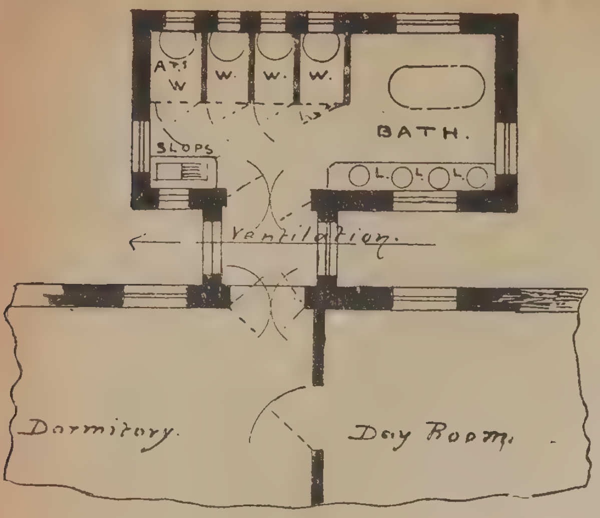

Fig. 38.

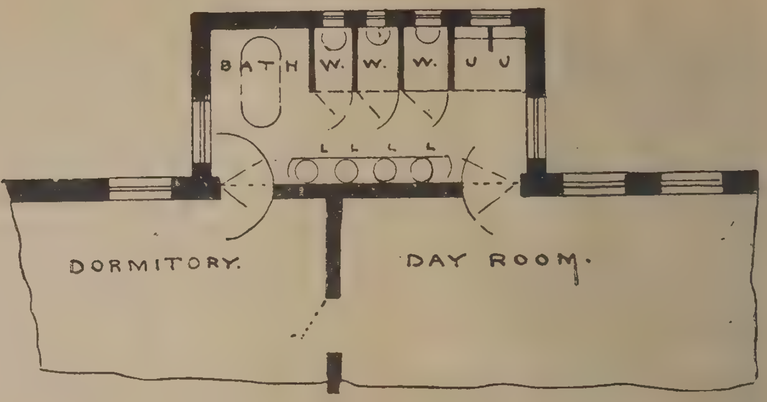

Fig. 39.

nfluence upon his eye. When I found that the black Pompeian decorations of my early Antwerp studio made me paint my pictures too heavy, I had my next studio painted red. Then they got too hot. So, arriving in Brussels, I painted my studio light green; and, when arriving in London, my first studio was blue and green, &c. The influence of all that was such that you can classify my pictures by the influence produced by the surroundings. If such is the immediate effect produced upon the work, it stands to reason that the influence exercised by the surroundings upon the taste of the man who lives daily amongst them must be equally great. Therefore, do not underrate the value of what are called the minor arts. Art is everywhere, and the more it is considered the better for every one; the more you take you vocation *au sérieux* the better it will be; and the more you know about it the better it will be for those who have to learn from it. To know in art is of the greatest necessity. If you know how a plant grows you will be able to render it. If you do not know you will mistake forms for what they are not; for nature is much too complex and far too complete for an untrained eye to understand without knowledge. For instance, a shepherd knows every individual in his flock. I am afraid that few of us would distinguish one sheep from another sheep. A gardener in midwinter will tell you which is an apple-tree and which is a pear-tree. How many landscape painters are there who would be able to do the same? I do not mean that a work of art must give everything the artist can see. What is required is that every touch, every line, slight as they may be, must render the feeling of what it has to represent; and that is not to be done without the necessary knowledge. Some say anatomy is superfluous; but is it possible to find anatomical errors in the masterpieces of the Greeks or the Italian Renaissance? So they must have known anatomy, as it is impossible to be correct without knowledge. I defy ny painter to paint a view of a building without any knowledge of perspective, or to draw a hand without any knowledge of the bones that are within. When a Velasquez summed up in after life with a few well-understood touches and was able to give us those incomparable masterpieces, it was because he had begun so very elaborately. In his picture, belonging to the Duke of Wellington, "The Water Carriers," even the drops of the water running down the pot are finished to the utmost. And so in Rembrandt's so-called "Night-Watch," which is still preserved in the Amsterdam Museum, when looked at quite near, you can well make out the pattern of the lace on the yellow man in the centre, and the drum to the right is rendered so minutely that not a nail fails. Everybody knows by now, through the interesting photographical researches of Mr. Muybridge, that the horses on the Elgin Marbles are the only ones of which the action is true. Are they not the more beautiful for it? And are not those horses preferable to the rocking-horses of the 17th and 18th century? How could a writer give in a few words the deep thoughts and feelings he succeeds in giving if he did not know them thoroughly? If a Holbein succeeds in giving with but an indication of a line more than another artist can do, it is because he knows more about it. To know enables one to render; not to know enables one to blunder. To know enables one to teach; but who can teach without knowing?

COUNTY LUNATIC ASYLUMS.—XXIII.

By George H. Bibby, F.R.I.B.A.

SANITARY BUILDINGS.

However perfectly an asylum may be constructed, lighted, heated, and ventilated, unless there be a thoroughly complete system for the removal of refuse and waste matters, there must always be a risk of the outbreak of typhoid fever, diarrhœa, diphtheria, cholera, ophthalmia, and other diseases; therefore the thorough and speedy removal of all waste matters is of the utmost importance.

A medical superintendent states that "in few asylums is the provision of water-closets sufficient for the population, and the insufficiency leads to constant squabbling and contention among the patients." The proportion, he says, should not be fewer than one to twelve.

In many asylums the closets are placed in small buildings, or annexes built away from the wards, and connected therewith by narrow neck-passages in the manner frequently to be found in modern hospitals, the idea being to obtain cross ventilation between the closets and the main buildings. Some authorities, however, contend that such arrangement (however excellent, to a limited extent, in connection with fever and other hospitals), are unsuitable for asylums, and for the following reasons:

In the first place this arrangement of the closets occasions considerable difficulty in reference to the necessity of a sufficient supervision and *inspection* of patients in the closets—a matter manifestly of the utmost importance if the liability of many of the inmates to commit suicide or misconduct themselves be duly considered. In the second place, some authorities are of opinion that where the closets are cold and the wards warm, there is a tendency for the air to pass from the closets into the main building through the neck-passages (vide Fig. 38 and 43).

Another medical authority prefers that the water-closet buildings should be connected with the wards in such manner as is shown in Figs. 39, 40, 41, or 42.

In Fig. 38 is shown an annexe containing three patients' closets, one attendant's closet, four lavatory-basins and slop-sink. It will be observed that the windows of the dormitory and day-room are placed opposite to windows in the annexe, for the special purpose of affording the attendants and nurses an opportunity of keeping the patients in view, to some extent, without having to actually follow them—which latter precaution, however, is frequently necessary with certain

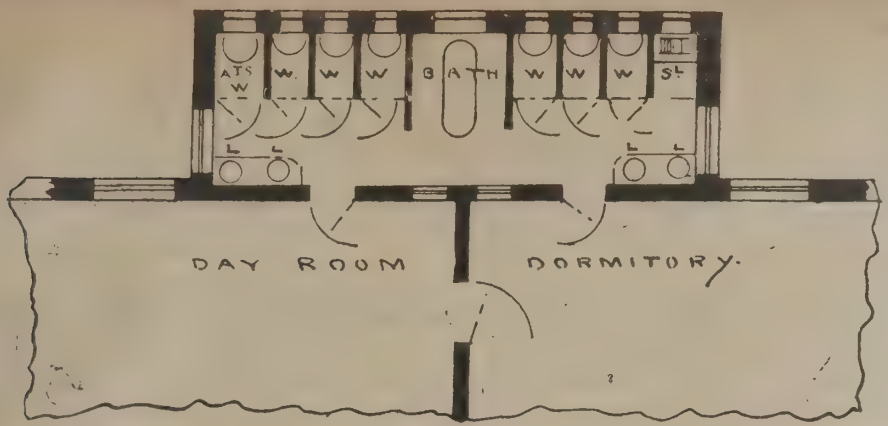

Fig. 42.

classes; many are less capable than very young children, and have to be treated with great care and attention to prevent them from becoming offensive to themselves and those with whom they have to associate. With this difficulty in view, a bath may conveniently be placed in the annexe, as well as a few lavatory basins.

In Fig. 39 is shown an arrangement of water-closets, urinals, bath, and lavatories in which the lavatory is made to answer the purpose of separating the closets from the wards; the doors between the lavatory would have glazed panels, and would serve, therefore, as inspection windows. The partitions between the closets would be about 6ft. in height: it would be unnecessary to make them higher, or to box them up to the height of the ceiling. The doors would of course open outwards, and it would be well to provide these with light closing-springs. To facilitate the work of the attendants, the doors of the closets should not come within 1ft. 3in. of the floor; there should be no projections, brackets, bars, or fixtures of any kind to which it would be possible for a patient of suicidal tendencies to attach a rope. The inside walls and floor should be made perfectly impervious, so that impurities cannot soak into them. For this purpose there is nothing better than glazed bricks or tiles: they form a perfectly smooth surface, and are easily and thoroughly cleaned. If the expense of such a method be objected to, then let there be a dado only of glazed tiles, say 6ft. in height, and the space above covered with hard cement, which may be afterwards painted and varnished.

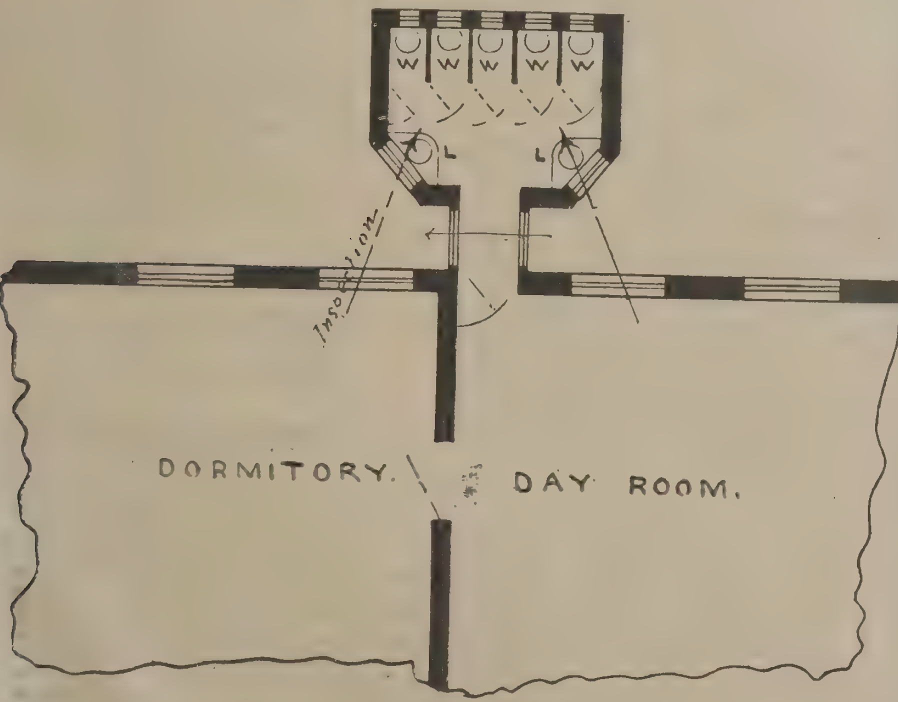

Fig. 43.

In Fig. 40 is shown a small annexe for water-closets, lavatories, and slop-sink only. This is suitable for the use of those patients occupying an adjacent day-room and dormitory, and who, being of clean habits, would take their baths elsewhere in the asylum. The closets are sometimes used as urinals (having a lifting seat), and may then be used also for slops, &c. A great point in the arrangement of asylum water-closets for patients is that the whole shall be schemed so as not to be unpleasantly and obtrusively brought under the observation of the inmates generally, but at the same time with full facilities for inspection without the nurses, &c., having necessarily to leave the day-rooms, or dormitories.

In Fig. 41 is an arrangement of a plan for an annexe when at the corner of a day-room, where it may occasionally be convenient to place it, and where, as in this instance, it is required to secure exceptionally close observation of closets which may be occupied by dangerous, suicidal, epileptic, or troublesome patients. The outer doors having glazed panels, it is obvious that the interior of this annexe would be well under the inspection of a nurse or attendant in almost any part of the adjacent day-room. Here it may be mentioned that for epileptic patients the old form of seat is to be preferred, as it protects them, to some extent, from falling *sideways* to the floor during their fits.

In Fig. 42 is shown another arrangement of an annexe, in which due provision is made for the attendants' and patients' closets, a bathroom, lavatories, and slop-sink. Here the glazed panels in the doors and inspection windows would afford a sufficient means of observation of the patient by the nurses, &c.; but it may be noted that an *excessive* provision of inspection windows is to be deprecated, as it is detrimental to the patients' interests that they should in *all* cases *know* that they are constantly under close observation. Attention has been already directed to a similar point in reference to the patients' single rooms.

In Fig. 43 will be found another form of annexe for closets and lavatory only (unless the closets should have the lifting seats for urinals and slops). Here there are three means of inspection: through a door, and two windows from the dayroom and dormitory. An advantage of this plan is that the annexe would not unduly obscure the light for the dormitory and dayroom windows.

Opinions are divided as to whether or not automatic flushing arrangements (actuated by the door, seat, or other means) should be used in asylums. A medical man writing upon the subject states: “Our object is not to treat insane patients as reasonless animals, but to give them an opportunity for the exercise of their faculties, and to encourage and urge them to give those faculties employment. If everything is to be done for them by automatic machinery, they will not recover their faculties by using them.”

In making arrangements for the sanitary buildings of an asylum, it is most necessary that the comfort and convenience of the attendants should be thoroughly provided for. The habits of the patients are in some instances revolting beyond all powers of description, and anything constructionally practical that the architect can suggest, with a view to mitigate their distressing duties, cannot fail to be acceptable.

An association has very recently been formed, having for one of its objects the purpose of drawing public attention to the classes of persons of both sexes who are engaged in performing the duties of attendants in asylums. In a speech upon this subject Sir Benjamin Ward Richardson remarked that: “He had never yet been able to meet with a correct description of these ‘asylum attendants,’ as they were generally called. Beyond this, the establishment of such an institution as that which was now about to be founded (the Association of Asylum Workers), would bring home to the mind of the nation some idea of the anxieties and responsibilities which fell to the lot of asylum attendants. It would show how much those persons had to do, the heavy and sometimes appalling duties they had to perform, and how hardly they were occasionally treated. It would be the object of the society to make the lives of these people better and happier, and, at the same time, to more thoroughly fit the attendants for their duties. The great aim of the association would be to inculcate among those with whose interests it was intended to deal, patience, firmness, kindness, courage, knowledge, and judgement, so that as public servants they may be made thoroughly competent for their respective positions; beyond this, the society would endeavour to render whatever service it could to the insane themselves, through their attendants. In general hospitals there had been during the last half-century a revolution in the matter of nursing the sick, so that sick-nursing had really become a sort of highly-educated profession, to the immense benefit of the sick; *while no commensurate improvements had taken place amongst the attendants of asylums.* It is for the interest of the insane that asylum attendants should have the highest position compatible with their work, so that the varied and yet limited and repeated phases of insanity might become scientifically known, with proper methods of management scientifically familiarised. Lastly, every effort should be made to relieve the attendants of asylums, to the advantage of the insane themselves, and rendering insanity less dreaded and unconquerable as a disease.”

The lavatory basins should be sufficiently divided from centre to centre so that the patients using them shall not be liable to jostle each other. They should be supplied with both hot and cold water; but the pipes for supplying hot water to each range of basins should have a valve so arranged that the attendant or nurse may be able to turn off the water from all the basins, so that patients may not be able to scald themselves, as some of the more demented are liable to do. The basins should not be cased-in below, but be open and free for inspection and cleansing purposes.

In all sanitary annexes attached to dormitories there should be provided slop-sinks, supplied with both hot and cold water, also a cupboard or receptacle for a *given* number of brushes, &c., all arranged so that if one be *missing*, the circumstance shall be known at once, and for the special reason that a brush-handle may become a dangerous weapon in the hands of an insane patient.

The sanitary annexes should never include within them the sculleries: these are best kept quite separate (and should be kept locked up from the patients.) They should also be supplied with hot and cold water, with plate-racks, dressers, table, towel-roller, &c., and be planned by the architect with special reference to the wards of the particular class of patients for whose benefit they may be intended. For instance, minor cooking operations, and the warming of the food for sick patients, need not be provided for in the sculleries attached to the wards for the able-bodied patients.

(*To be continued.*)

THE CORROSION OF UNDERGROUND PIPES

SOME years ago pipes, whether of cast or wrought-iron, steel, or other material, when laid underground in soil fairly favourable to their durability, might count upon a tolerable longevity. Notwithstanding the large number of all sorts and sizes placed in almost complete juxtaposition, they were good friends and neighbours and lived happily together. In the end, they had certainly all of them to succumb to the inevitable *tempus edax rerum*, but the cause of their gradual deterioration and final decay proceeded from what may be termed natural agencies, and not from the insidious attacks of foreign foes, which, we are about to point out, prevail at the present time. That natural agencies, due to the analytical constitution of the substratum in which the metal pipes are imbedded, and to the leakage always present to some extent, however slight, in gas-mains and frequently in water-mains, do give rise to a certain amount of chemical action, inimical to the life of the underground pipes, is incontrovertible. At the same time, this action, even when the pipes are laid in ground partly saturated with nitre, ammonia, and other ingredients and salts of a most deleterious and corrosive character, will not account for the examples of the violent and rapid manner in which gas and water-pipes are now constantly assailed. It must be kept in view that this is a subject deservedly demanding the closest and most attentive consideration, and also one the importance of which is only equalled by its enormously extensive sphere of action. In the whole of the United Kingdom there is not a town or village possessing a population worth counting in which metal pipes are not laid underground for some purpose or other. If this new cause of sudden and swift deterioration, to which we shall refer, were productive of no other results than the destruction of the mains and subsidiary pipes themselves, and the consequent cost of the renewal of them, the matter would be serious and grave enough; but when, in addition to the mere cost of numerous new pipes, are added the injurious effects which, it is very probable, may be exercised upon the public hygiene from the duplicate leakage both out of and into pitted and corroded metallic pipes, the gravity of the situation becomes very considerably accentuated. Experiment and analysis have previously determined that the subsoils of all roads and streets, independently of the manner in which, and of the material with which, the surface may be paved, contain very appreciable proportions of various soluble chemical salts, all of which are more or less injurious to the life of metallic pipes. Among the principal of these pipe-corroding ingredients, in virtue of the destructive chemical reaction they set up, may be included the nitrates and chlorides of potash, soda, and ammonia. Under these circumstances, which it must be borne in mind have always existed ever since pipes were laid underground, the ordinary duration of the life of a metal pipe might be put at from eighteen to twenty-two years. Pipes have lasted very much longer under exceptionally favourable conditions, but these cannot be fairly included in arriving at a general average of longevity. When, therefore, we find, on undoubtedly sound authority, that an underground metal pipe, 7in. in diameter, was so extensively corroded after about half-a-dozen years of service as to require renewal, it is evident that we must look to some other source than simple chemical reaction for results of a nature so destructive and possibly so disastrous.

It is only very recently that the investigation necessary to discover this new mysterious and dangerous agent has been set on foot. The inquiry and experiments, invariably inseparable from all scientific and technical researches of this character, have led to the utter abandonment of the theory that the corrosion of metal pipes of the magnitude recently discovered could be attributed solely to chemical reaction constantly and always pre-existing. They pointed in the most unmistakable and conclusive manner to the fact that there must be some other agent, hitherto secret and hidden, which must be held responsible for the destructive work so speedily and thoroughly accomplished. It had not escaped general notice that it was not until the introduction of electric installations for lighting and for tramway and railway haulage, with all the accessory conductors, wires, and return currents, that the normal comparatively sound condition of underground metallic pipes was so seriously and suddenly impaired. Clearly that invisible, imponderable, and irresistible electric power was concerned in the change. To what other agent could the eating away of a pipe in the course of a couple of months be attributed? The conclusion arrived at—and from the evidence available it appears to be the only one that could be arrived at—is that the mischief is occasioned by the electrolytic action of the return currents, exercised either directly upon the metallic pipes themselves, or first upon the soluble salts in the subsoil, and subsequently by secondary reaction upon the pipes. Into the question as to which of these two hypotheses has the better claim to the truth it is not our intention to enter, although it is but fair to state that the second appears to have the best of the argument. Either cause would be sufficient to effect the corrosion by itself, and it is not at all improbable that both may have their full share in the work of destruction.

Without entering into any electrical details of a purely technical nature which are not quite suited to the columns of the BUILDING NEWS, it is a simple matter to explain briefly the character of the occurrence and the means to be adopted to counteract it. Our readers are well aware that in sending a current of electricity from one station to another there must be some means provided—that is, some conductor—by which the return current can transport itself back from the second or receiving station to the first or sending station. Until this return is properly effected, the "circuit will not be closed," and there will be no manifestation of any electrical result whatever. In the early days of the old needle telegraph two wires were laid, one being the supply or leading conductor and the other the return wire; but in 1838 Steinhill discovered that the earth itself could be employed as the return wire or conductor, and he so used it. This led to the disuse of the second or return wire. It is just possible that in those times, when electrical conductors underground or along the surface were few and far between, there was, so to speak, plenty of room for the return passage of the current "by earth," and of the metallic pipes, also few and far between. The case, however, is now widely different. Scarcely a week—we might almost say a day—passes without some roadway, some footway, frequently almost immediately after it has been renewed and relaid, undergoing the process of being ruthlessly ripped open and literally torn to pieces by a gas, water, or, perhaps, a rival electrical installation company. The consequence is that the return current, in countries where very extensive systems of railways and tramways exist, does not find its way back through the tangled congeries of metallic pipes and conduits without experiencing considerably more resistance than the sole conductivity of the earth would give rise to. In, as it were, retaliation for the obstruction it is subjected to, it attacks the pipes and seriously pits, corrodes, and, in some instances, has been known to actually perforate them through and through. The whole of the injurious effects described is known to be due to the imperfect character of the return circuit, and a radical cure can only be accomplished by making the return circuit by means of conductors possessing as high a degree of conductivity as those constituting the supply circuit. In a word, the aid of the earth as a conductor must be altogether neglected. When electric tramways and railways were in their infancy, the ordinary rails of the track, which were not insulated, were relied upon, in conjunction with the earth, to convey the return current back to the sending station or generator. Experience shortly demonstrated that the current refused to restrict itself to this particular route marked out for it. It is now well established that the true means for averting an evil which recently promised to be of a very formidable character, consists in uniting the different systems of rail tracks, water and gas-pipes, so as to provide as perfect a return current as the circumstances of each especial case will permit of. Electrolysis and the subsequent destruction of the pipes, primary or secondary, will then practically be at an end.

CLASSIC DETAILS AND THEIR APPLICATION.*

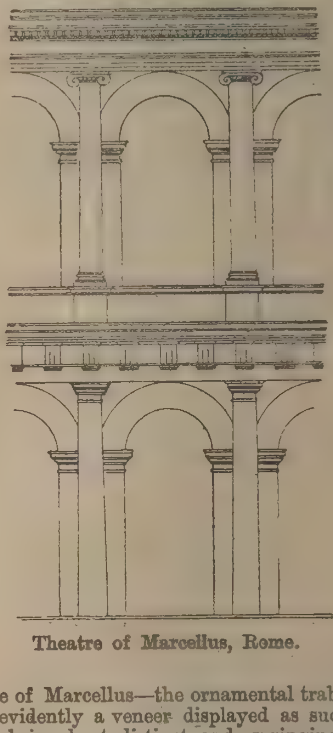
By G. A. T. MIDDLETON.

VI.—CLASSIC TIMES: THE ARCH.

THOUGH known to previous races, the arch was first used as an architectural feature by the Romans, and it was employed by them to so large an extent that arcuated construction was far more common in Roman work than was trabeated. By its employment large spans could be bridged even where the only available material was a stone of small dimensions, and vaults and even domes were rendered possible.

In spite, however, of the great gain thus secured, and of its large employment by the Romans, they did not spontaneously develop an architecture based upon the arch, but imported the trabeated forms of Greece; and thus came about the reign of an architecture whose construction was arcuated and whose ornament was trabeated.

At first always, and afterwards generally, this was boldly acknowledged, the result being somewhat like that of the example illustrated—the Theatre of Marcellus—the ornamental trabeation being evidently a veneer displayed as such, the arches being kept distinct and springing from imposts of their own, mere mouldings passing at the springing level round the supporting piers, and interpenetrated by the columns of the applied Orders. With careful proportioning, the effect was good, and, in spite of the entablatures being apparently carried principally by columns, which in reality did no work at all, and at intermediate points by just the crowns of arches which did all the work, there has been but little outcry against the practice.



Theatre of Marcellus, Rome.

Much less defensible were two other methods of combining the Orders and the arch, which came into use in the later Roman period, and of which illustrations are given, both taken from the Palace at Spalatro. In the arch to the porch of the vestibulum it will be seen that the horizontal entablature has been bent round to the arch curve, as if solid stone were pliable; and in reality the effect is much worse than this drawing would lead one to expect, as there is a pediment over, the raking lines of which clash with the curved lines of the arch.

Bad, however, as this bending of the entablature was, it seems to have given the inspiration for the true method of decorating an arch by mouldings, as in Romanesque and Gothic work, even the hood-moulding being present in the form of the cornice. An intermediate step towards this, indeed, is seen in the upper niches to the Porta Aurea at Spalatro, where the detached columns are each crowned with a complete entablature (debased, of course), forming a species of deep abacus above the cap, from which the arches spring—a method of treatment which was by no means uncommon. It can rarely, if ever, be considered satisfactory, and certainly the whole meaning of the entablature must have been lost sight of before it could have been dealt with in such a way; but its interest is considerable as a stage in the development from the Classic of Rome to the Byzantine of the East and the Romanesque of the West. In fact, in the example before us there are already indications of Byzantine feeling, in the reintroduction of the spiked acanthus, in its very low relief (or, rather, in the slight sinking of the background upon which it rests), and in the use, immediately above the architrave, of a splay instead of a moulding, and this enriched with a scroll completely wanting in design.

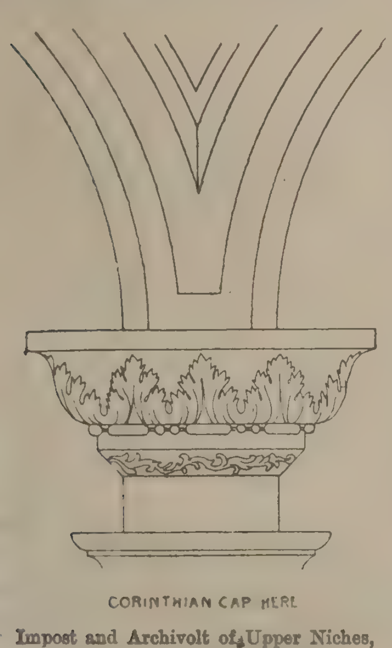
Arch from the Porch to the Vestibulum, Palace at Spalatro.



Impost and Archivolt of Upper Niches, Porta Aurea, Palace at Spalatro.

With neither the Eastern nor the Western styles which arose upon the remains of the Roman can the student of Classic work have much concern, and to him Classic architecture may well be said to have died with the migration of the seat of empire to Constantinople, to be revived only in the time of Brunelleschi.

* * *

THE INTERNATIONAL HEALTH EXHIBITION AND CONGRESS, PARIS.—II.

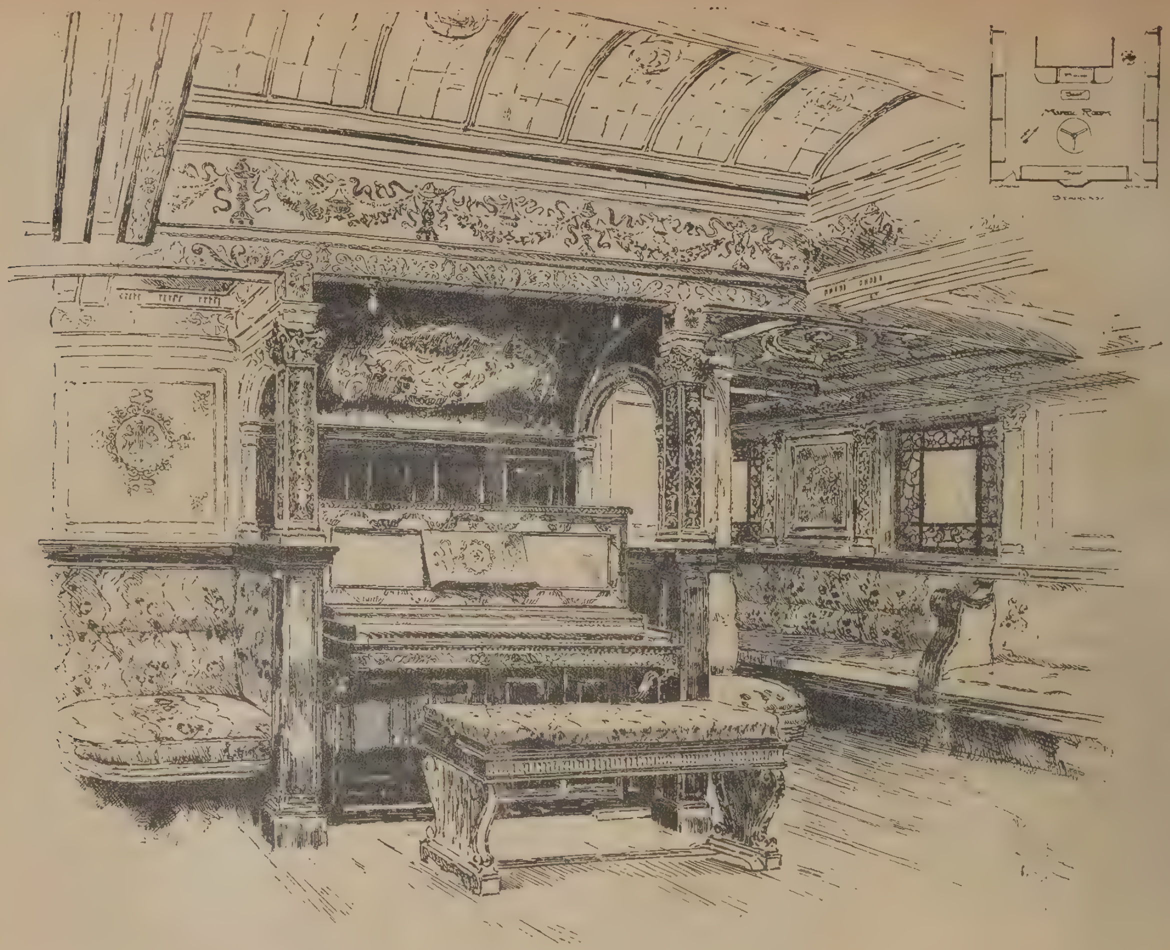
THE interesting Sanitary Exposition at the Champ de Mars, and the important Congress of Sanitary Architects and Engineers which has just been held at Paris, prove that France is now waking up to the great importance of the proper study of sanitary science and its practical application, and the fast-growing Society of Sanitary Architects and Engineers, which has just been formed, will show us that the Frenchman is not going to be the last to do all that is possible to help making life worth living, in at least as far as concerns all the comforts and conveniences which sanitary science and modern industry can produce, in teaching and encouraging workmen and those whose duty it concerns to use their best efforts in furthering this end, and in interesting the general public in this great question, and lead it to appreciate to a greater extent the utmost importance of cleanliness in sanitary measures in everyday life. And the remark made to me by M. d'Esmerand, chief secretary to the Society, and moving spirit in the vigorous organisation of the Exhibition and Congress, that before ten years have passed we on this side of the Channel shall have left you others far behind us in sanitary science and practice, although seeming somewhat of a boast, on second thoughts may not be devoid of reasoning, when it is considered that the Frenchman, almost ignorant up to a very recent time of sanitary matters, is now studying up the question in a very earnest manner, and although basing his first principles and practical application on what he has learned from his neighbours, and especially from his English neighbours, will certainly follow up the matter in a spirit entirely his own, and suited to his special needs and ideas, producing by natural evolution a result which his neighbour, hampered by tradition and experience, may possibly not attain.

The first duty of the Congress was an invitation visit to the inauguration of the aqueduct of Achéres, and the lands for spreading and purifying drainage matter coming from Paris. The opening ceremony was performed by M. Foubelle, Prefect of the Seine, who delivered an interesting speech, giving the history of the work of sanitation already done. The Prefect stated that the main sewers from Paris delivered into the Seine about 14,000,000c.ft. of sewage per day, or over 5,000,000,000c.ft. per year, containing at least 10,000 tons of nitrogenous substances estimated as valuing £800,000, a therefore important annual loss of fertilising matter. Since three generations, engineers such as Alphand, Mille, Couché, and Durand Claye had been endeavouring to prevent this waste, and now at length an important result had been achieved, and the principle of all drainage to the drains, nothing to the river, was accepted, and was being put into practice. When visitors from all parts of the world will be flocking to Paris to pacifically celebrate the arrival of the new century, at the 1900 Exposition, they will be able to admire the perfect organisation of the drainage system, and the healthy state of the French capital. The Prefect continued with an extremely eloquent discourse, putting forward the benefits to be derived from the careful and proper study of sanitary science and practice, likening the sanitary organisation of a large town to the working principles of the human body with its canalisations, circulation, supply, arteries, and veins. M. Baudin, member of the Chamber, spoke of the extreme desire of the Paris Municipality to avoid endangering any of the interests of the districts surrounding the city; but rather by the sending of the sewage over the dry plains to enrich the resources of agriculture, and put under culture a large surface of land which was up till now unfertile—almost useless. Several speeches were made by members of the Congress, followed by a luncheon-banquet at Argenteuil. A visit was afterwards made to Achéres, where an inspection was passed of the 2,000 acres of land destined for the spreading of Paris sewage, and an inauguration of the first trenches was made. In the evening, the members of the Congress were invited to a reception given by the Minister of the Interior, and a well-earned stroll and repose in the vast gardens of the palace—repose, however, somewhat disturbed by the unpleasant odour and noise of a cesspit pumping-machine, carrying off the drainage matter from a neighbouring mansion, recalling the members to a sharp sense of their coming duties.

The serious work of the Congress commenced on the following morning at the Palais des Arts Liberaux, in the Champ de Mars, the meeting being presided over by M. Monod, chief of the Sanitary Service of France, who gave a flattering welcome to the representatives of the British Association of Sanitary Inspectors present at the Congress. Each member received a printed report of the chief subjects to be brought up for discussion, each subject having its appointed reporter, and terminating in a series of resolutions. Each member was therefore well aware beforehand of the various subjects on which he would have to vote.

The first important question discussed by the Congress was that brought up by M. Petsche, engineer, relating to the disposal and utilisation of domestic refuse, town dustbins, and waste matter. This engineer pointed out that from 7lb. to 11lb. of nitrogenous substances, worth about 4s. to 6s., were contained in a ton of Parisian domestic refuse; from 7lb. to 11lb. of phosphoric acid, worth from 10d. to 1s. 3d.; 5lb. to 9lb. of potash, worth from 9d. to 1s. 2d.; also from 65lb. to 90lb. of lime, worth from 3d. to 5d.; in fact, roughly speaking, the estimate of the value of a ton of house refuse might be put at from 6s. to 9s. This refuse from the houses of the whole of Paris, worth about £200,000 per annum, is sold by Parisian contractors for from 8d. to 1s. 3d. per ton delivered on railway trucks, the charge by the railway companies for transit being from 2s. to 2s. 5d. per ton; the cost of the manure placed on the fields comes to from 2s. 8d. to 3s. 8d. per ton. The utilisation of this refuse will probably greatly increase, but M. Petsche asks if the danger of carrying to all parts of the country such a large quantity of refuse, portions of which may be highly infected, is not a great one. The reporter followed up with a description of the various systems and destructors employed in England, America, and other countries, giving his opinion on these various methods, and asking the members of the Congress to discuss the matter with him. M. Bechmann, engineer of the town of Paris, proposed that the building of shafts down which all refuse from kitchens could be thrown, be encouraged for all the large immeubles; in this manner no rubbish would remain for any length of time in the apartments. It was suggested by some of the members that it was doubtful if such shafts could be kept clean, and would not, sooner or later, emit foul odours. It was remarked that such shafts existed some time since in a number of the Victoria-street flats at London; but as Mr. E. Tidman, sanitary inspector for Westminster, was unfortunately unable to be present at this first meeting, his information as to the working of this system was not forthcoming, to the regret of all. M. de Montricher explained the successful system he has employed for fertilising the dry plains of Crau by means of town rubbish brought from Marseilles. He stated that the refuse was carried away and loaded at night-time on railway tracks situated at a depot at some distance from habitations and away from the passenger stations. The first question of getting rid of refuse from the kitchen of apartment flats becomes of more importance each day, for the number of houses built as flats is increasing rapidly in the large towns, and the use of dust-bins in the yard is almost impossible in such cases. The discussion was also taken up by MM. Richou, Tasson, Lucas, Baume, and Smith (chief correspondent of the *Lancet*), and the following resolutions were passed:—That the collection of domestic refuse should be made daily, very early in the morning, the rubbish being carried away by special carts, with covered iron reteptacles permitting easy disinfection; that, in order to facilitate the utilisation of such refuse, the railway companies should reduce their tariffs, and arrange for special isolated depots for loading the refuse; that the destruction by fire of such refuse was the most satisfactory solution in a health point of view, if the conditions and temperature of the combustion was sufficiently high and could be sufficiently prolonged. In this case, such a solution was the most economical in practice, and that all encouragement should be given to make further researches after a means of utilising the products given off during combustion and those remaining. A further resolution was made that the various municipalities should encourage, by every possible means, and especially by the reduction of the scavenging tax, the direct and daily evacuation of house refuse from the interior of dwellings.

M. Jourdan then read his report concerning the regulations of private roads, raising a vigorous discussion on this subject. The reporter said that the general state of these roads left much to be desired in a sanitary point of view; no regulations determine the minimum width of private roads, or again (except at Paris) the maximum height of the bordering houses. It often happened that the construction of buildings of an exaggerated height in streets much too narrow prevented both the air and sunlight from freely penetrating into these kind of passages. In many cases, also, the



MUSIC ROOM, "TANTALLON CASTLE."

maintenance of the roadway was deplorable; water was often lacking not only for the use of the inhabitants, but also for the proper cleansing of the gutters, and it often happened that even drainage had been neglected. Such being the case, it was not surprising if such streets often became a very nest of sickness and infection, and it was high time that something should be done to regulate this matter. It is here that the municipality has the right to close in these private streets at their outlet into the public roads, if the proprietors are not willing to provide the proper and necessary sanitary work; but, again, the municipality has not the power to determine the nature and importance of the work to be done. In several cases the proprietors prefer having their street closed in, to going to the expense necessary for sanitation work. The Mayor of Marseilles remarked that in his town there existed a large number of streets which were to all purposes public thoroughfares, but being private property he had no right to inspect or control them, and that this was the case in many towns. The reporter desired that no private way could be opened without the authorisation of the municipal authorities, who would fix the minimum width of such roadway. The height of the bordering building should also be regulated, the proprietor being enforced to construct his roadway according to one of the methods established for public roads, to arrange proper drainage and water canalisation, lighting, and street cleansing. The Congress passed the resolution that all roads and ways frequented by the public and inhabited by different persons, not the property of a town or commune, should be subject to the same rules and regulations, inspection and control, as regular public thoroughfares.

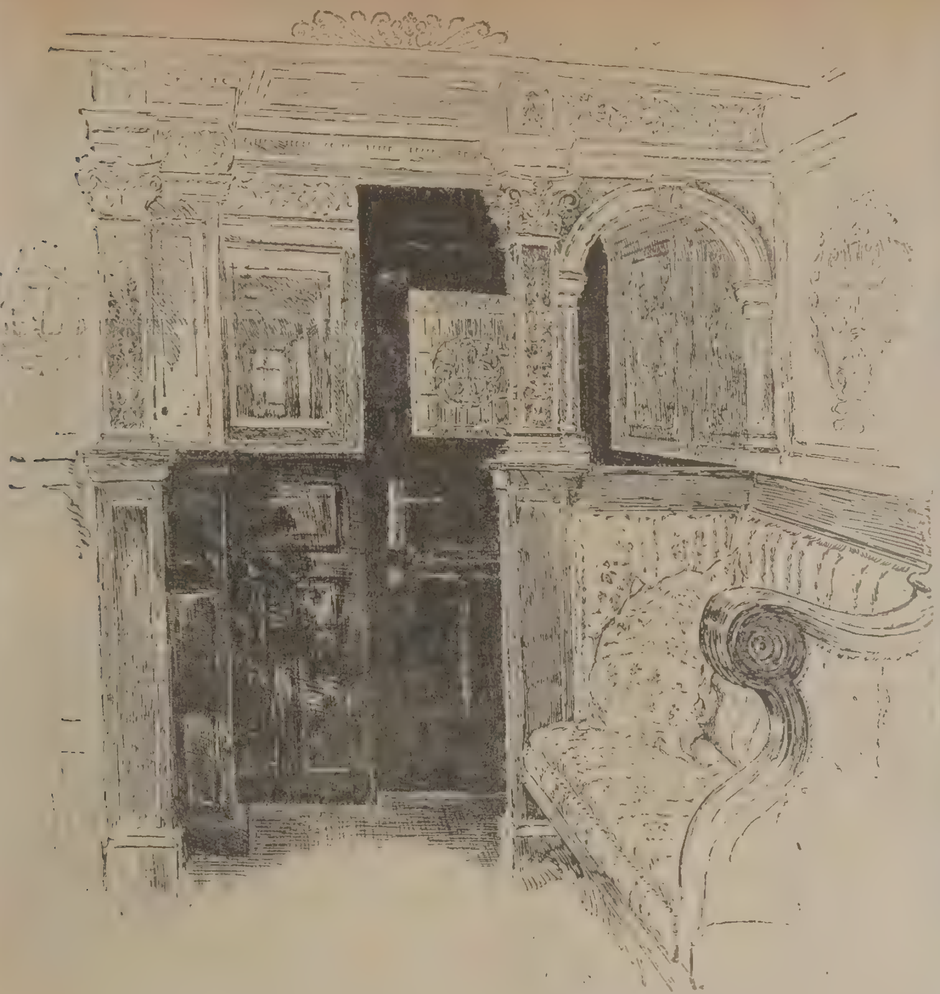
At the afternoon sitting, M. Chardon, engineer, explained the system of pneumatic drainage now applied at Levallois-Perret. This is an adaptation of the well-known Berlier system, in which the complete combustion of all gases arriving from the vacuum drainage pipes was obtained by making them pass through the furnaces of the boilers. The application of this system made at Levallois-Perret was perhaps not perfect, even in the idea of the reporter; but, in any case, the foul-smelling cesspits had been abolished, and all sewage was now removed from the dwellings without any fouling of the sewers, and all escape of evil-smelling sewer-gas was obviated. A visit was made to the works at Levallois-Perret, and the members of the Congress were enabled to judge of the efficiency of the system, and study the arrangement of a powerful but economical steam-jet producing the vacuum in the reservoirs, receiving the matter from the drains by pneumatic suction. The system is stated to be an exceedingly economical one, the simple steam-jet producing the necessary vacuum, and doing the work as easily and as well as steam machines, of which the cost was many times that of the steam-jet. The Congress visited afterwards the municipal disinfecting station of the Rue des Récollets, arranged after the plans of M. Bouvard, architect, the working of the disinfecting furnaces (system Geneste and Herscher) being explained by Dr. Martin, chief of the service of dwelling sanitation.

ARTHUR VYE-PARMINTER.

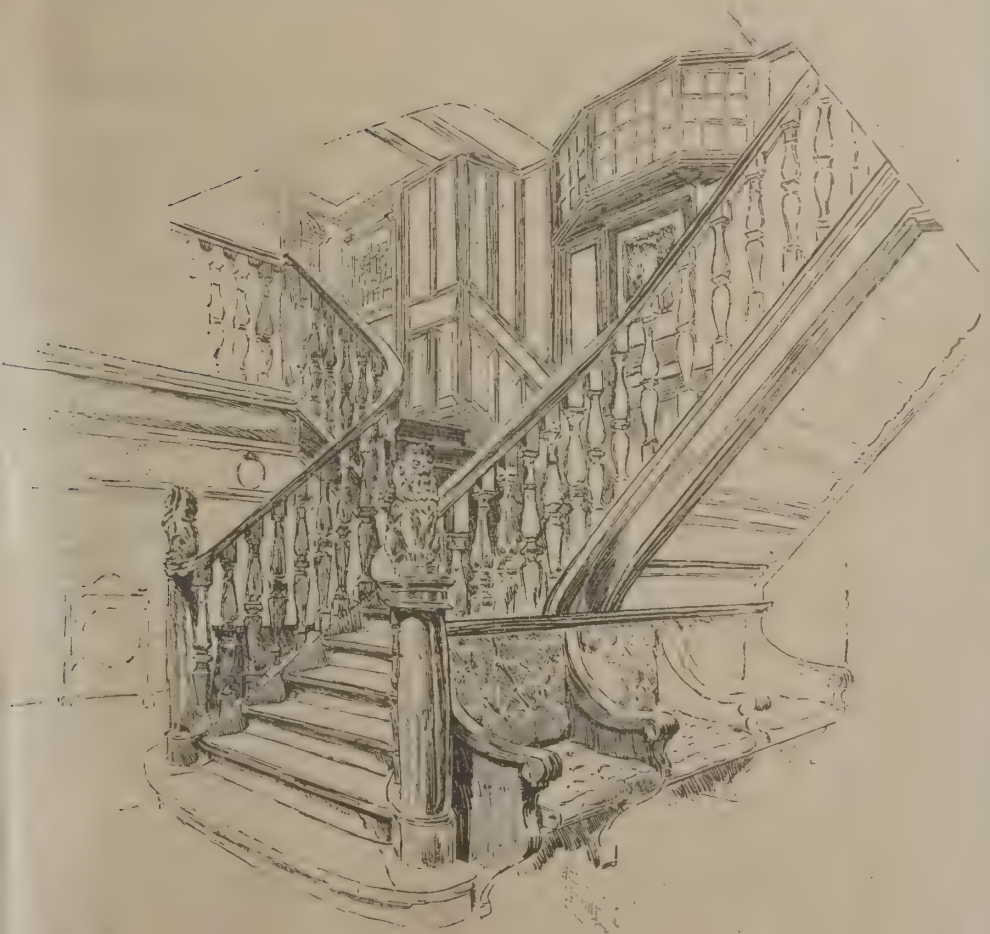
THE "TANTALLON CASTLE."

SIR DONALD CURRIE'S desire to see a complete series of drawings published of this great Castle mail liner has been admirably realised, and the sketches are from the pencils of Messrs. W. L. Wyllie, A.R.A., W. Hatherell, R.I., Joseph Pennell, A. S. Hartrick, N.E.A.C., and D. B. Niven, A.R.I.B.A. The story of the Castle and of the ship is told by Elizabeth Robins Pennell in a handsome folio, in which the pictures are incorporated, showing, as the preface says, that a beautiful book may be made of a beautiful ship. The graphic authoress describes the stronghold of the Lords of Tantallon as it stands at the entrance of the Firth of Forth, rising sheer and inaccessible from the sea, the safeguard for the Douglas who dared to defy both king and barons. Its walls re-echo in fancy the commands of Archibald Bell-the-Cat, and the arches resound with the horseshoe iron of the troopers of Red Douglas. Tantallon Castle to-day personifies peaceful stillness, its happenings are of the past, and the ruin stands silent and alone in stately loveliness, in staunch massiveness, overlooking the great North Sea. The steamer fulfils the conditions imposed upon her at her christening: she has the strength and grace of her name. She rides more easily than larger boats over the Bay of Biscay, and passes unscathed under a tropical sun. Her length is 456ft., and she is 50ft. and more wide, the registered tonnage being 5,700 tons. The part of the vessel which interests us primarily is, of course, the fittings, which, needless to add, are of a particularly handsome and sumptuous character, entirely in keeping with the structural spaciousness and ample convenience of the ship. We are enabled to print some few sketches of the interior, which will give a good idea of the character of the work to which we refer. The decorators of the *Tantallon* know that all steamers need not be turned out upon the same pattern, though some things must remain virtually similar in shape and proportion. The music-room, shown by the accompanying views, has pale gilded walls, with damask in rose-strewn green for the long-cushioned seats. The piano is delicately inlaid in scale with the rest, and situated prettily in a coved recess. The staircase is an exceptionally handsome one, and the dining-hall is as gay and airy as any similar apartment to be found on shore. The white panelling is picked out in gold traceries, and the skylight is handsomely enriched with coloured glass. The kitchens and cabins are equally appropriate for their several uses; no expense having been spared to render the boat in every sense a floating palace in which the comfort of every class of the passengers and crew have been accorded suitable consideration. No horrors of steerage, and no cruel overcrowdings find a place, while the second-class quarters satisfy the most fastidious wants of the most exacting traveller, and there is air and space everywhere. The barber aids the daily enjoyment, and marble baths are provided. Even a printer and his press form part of the equipment, and electric-light is used throughout the *Tantallon*.

Decision has been given by Mr. Wm. Crouch, C.E., arbiter in the claim by Messrs. Charles Brand and Son, contractors, against the Glasgow District Subway Company for £45,667 11s. 6d., being the balance and extras in the formation of three sections of the subway tunnel. Mr. Crouch found the claimants entitled to £26,697 10s. 11d.



IN THE MUSIC ROOM, "TANTALLON CASTLE."



STAIRCASE, "TANTALLON CASTLE."

ENGLISH GOTHIC.

ENGLISH Gothic architecture, as exhibited in our cathedrals, was held somewhat cheap some years ago by Prof. Moore, of Harvard, who held that we never caught the full meaning of Gothic art. An article in the *Atlantic Monthly* for August, in which an American architect contrasts the cathedrals of England and France, shows that all Prof. Moore's professional colleagues do not share his opinions, especially that in France alone do we find the "whole structure of a cathedral and fully organised and visible framework which the wealth of the applied ornament only serves to emphasise." Mr. Peabody, the writer, of course, notices that the apsidal east end of a cathedral is almost unknown here save at Westminster Abbey, though Norwich, Peterborough, Lichfield, and Canterbury have circular ends, while, on the other hand, the square east end, almost universal in England, is found abroad only at Laon and a few lesser places. Then, again, the English cathedral is low and long, rather than narrow and lofty in its proportions. The splendid western front at Wells is 31ft. wider than that at Amiens, yet it is only half as high; and "the nave at Wells is but twice as high as it is wide, while that of Amiens is three times its own width." Yet, "by a strange contradiction," Mr. Peabody is ready to admit, "there is nothing about these English churches carried to a greater degree of perfection, or which brings them greater glory, than their clustered towers and their groups of heaven-seeking spires." The English architect clung firmly to the belief that a central spire, combined with the western towers, would produce a more pleasing effect than those towers alone, as the French designer thought. The result is that "no French church possesses a single central spire to compare with that of Salisbury or of Norwich," though "the western towers of the great French cathedrals, taken by themselves, are more grand and stately structures than similar features in England." The rich mouldings and clustered piers of Early English Gothic contrast with the plain capitals and simple shafts of the same age in France. English sculpture was developed more regularly, and from the first, in all but the figure, could bear comparison with the best French work. Taking up one point after the other in this way, Mr. Peabody makes it clear that the difference between the cathedral-builders of Mediæval England and France was principally a matter of temperament. The French architect always kept in view the great principle of Gothic art, which, in Freeman's words, was "an upward tendency of the whole building and of its minutest details." He delighted to exhibit his constructive skill in lofty naves and arches, in "a brilliantly conceived framework of pier and vault, of buttress and pinnacle." On the other hand, "the Frenchman," writes Mr. Peabody, "never formed such harmonious features of church and scenery as one sees at Salisbury and Lincoln—never massed spires in such gracious composition as we find at Lichfield and Lincoln." English Gothic, in fine, has its own place, though not perhaps the first place, in the master art.

BUILDERS' BENEVOLENT INSTITUTION.

THE 48th annual meeting of this charity was held on Thursday, 25th July, at the offices, 35, Southampton-row, Bloomsbury. Mr. Basil P. Ellis, the president, occupied the chair, supported by Messrs. George Plucknett, J.P. (hon. treasurer), Thomas Stirling, W. Scrivener, E. M. W. Goslett, and other friends of the institution.

The secretary (Major Brutton) read the annual report, which stated that the institution continues to carry into effect its purposes as usual, the only drawback being the need of increased income to provide for all the necessitous applicants who seek the benefits of the charity. This is especially to be regretted, because some are very aged before making their wants known. The committee's efforts have been much hampered by the diminution of subscriptions, consequent upon the death of so many regular subscribers, and this makes it an earnest and urgent matter to endeavour to obtain new subscribers and donors, in order to maintain the institution. This state of affairs cannot be too widely known to the patrons. A movement has been set on foot for the secretary to call and solicit subscriptions or donations from all members of the building and allied trades within the Metropolitan district, which, it is hoped, will be attended with good practical results. At the present time there are 46 pensioners on the funds, while others are waiting for election until the income is sufficient. Four female pensioners have died within the past year. One man and one woman have been elected. The committee strongly express their gratitude to the president (Mr. Basil P. Ellis) for the lively interest he takes in the transactions of the institution, and for his determination to get very liberal contributions to the charity. They also offer their thanks to the stewards of the annual dinner and to the honorary auditors for their services. The committee have further the pleasure to announce that Mr. John Mowlem Burt, J.P., D.L., has accepted the presidentship for the ensuing year, and will preside at the annual dinner on the 7th Nov. next, in the hall of the Worshipful Company of Carpenters, London Wall.

On the motion of Mr. Thomas Stirling, seconded by Mr. Goslett, the report and balance-sheet were unanimously adopted.

Mr. Plucknett proposed a cordial vote of thanks to the outgoing president for his exertions in aid of the institution during the past twelve months. Mr. Stirling seconded the motion, which was carried by acclamation.

The president returned thanks, and said that he was pleased that he had been able to do something for the charity. The success which had already attended the movement for increasing the number of subscribers was largely due to Major Brutton, who had been most assiduous in calling upon those who were likely to help. (Applause).

Votes of thanks were also passed to the vice-presidents and trustees, to the hon. treasurer (Mr. Plucknett, who was re-elected), and to the hon. auditors. The retiring members of the committee were also reappointed, with the addition of Mr. Ellis.

On the motion of the president, Mr. John Mowlem Burt, J.P., D.L., was elected president for the ensuing year, and a vote of thanks to the chairman for presiding closed the proceedings.

SEWER VENTILATION.

A PAPER on this subject was read by Mr. J. Parry Laws in the Public Medicine Section of the British Medical Association's Congress on Wednesday. The author said that the results of modern research have not only enlarged our knowledge of the causation and propagation of infectious diseases, but they have also shown that in many instances the exciting cause of the disease—namely, the specific micro-organisms—pass out of the body with the bowel discharges, and so gain access to our underground sewers. These facts have imparted to the subject of sewer ventilation a significance and importance unknown in earlier times. To find a thoroughly satisfactory solution to the question, Is sewer-air harmless or otherwise? and, if harmless, its mode of action, is of great moment to hygiene, for our attitude with regard to this all-important question must, of course, be profoundly influenced by the conclusions at which we ultimately arrive. Although the hypothesis which regarded sewer air as capable of disseminating the morbific germs of disease is, he thought, proved beyond reasonable doubt to be an erroneous one, we must not therefore forget the immense benefits and the saving of life that modern sanitation, mainly influenced by this hypothesis, has brought about. Whatever the ultimate verdict be, whether sewer air is harmless or otherwise, it will always be the imperative duty of those charged with the care of the public health to insure rapid and efficient removal of all sewage and refuse matter, and, above all, to guard against defective drainage and probable pollution of water supplies. The more light that is thrown upon the dissemination of those diseases which have been, he thought, erroneously associated with sewer-air, the more evident does it become that a polluted water supply, and, as an incidental result, a polluted milk supply, are among our most insidious foes.

NATIONAL ASSOCIATION OF MASTER BUILDERS OF GREAT BRITAIN.

THIS association held its thirty-fifth half-yearly meeting in the Arbitration Room, Royal Exchange, Leeds, a few days ago. Representatives were present from London, Liverpool, Manchester, Birmingham, Bradford, Huddersfield, Bolton, Derby, Preston, Leicester, Walsall, Hanley, Newcastle-on-Tyne, Bristol, Hull, Leeds, Southport, Nottingham, and Blackburn. The reports having been adopted, the President (County Alderman John Bowen, Birmingham) explained to the meeting the course which had been adopted in reference to the Plumbers' Registration Bill, and urged the desirability of opposing the Bill should it be again introduced. A letter was read from Mr. Stanley G. Bird, London, giving the result of negotiations with the Royal Institute of British Architects with reference to the proposed new form of contract, and expressing regret that, owing to the course adopted by the Institute of Architects in refusing to sanction the introduction of an arbitration clause in the form of contract, the whole matter had practically fallen through. Mr. John Dawson, Huddersfield, urged the members to insure themselves against the risk of accidents to their workmen. Mr. T. F. Rider, London, referred to the cause of the action instituted by the Master Plasterers' Association of London against the National Association of Operative Plasterers. It was decided that the association should render all the support it could, both financially and otherwise, to the Master Plasterers' Association of London. Reference was made to apprentices' indenture forms, some being drawn up in such a manner as to render the employer liable to maintain the apprentices when unable to work through illness. Mr. William Irwin, Leeds, was elected a member of the council to fill the vacancy occasioned by the resignation of Mr. Banks Mawson. It was resolved to hold the next half-yearly meeting in London. In the evening the members were entertained by the Leeds Master Builders' Association at dinner in the Queen's Hotel. Mr. Wm. Irwin cordially welcomed the National Association, and the President acknowledged the hospitality of the local organisation.

UNDERGROUND WORKSHOPS.

A JOINT paper on this subject, contributed by Dr. F. J. Waldo, Medical Officer of Health to St. George, Southwark, and by Dr. David Walsh, Western Skin Hospital, was read at the Congress of the British Medical Association on Wednesday. The tendency of civilised communities to flock towards particular centres of population has led to a vastly enhanced value for town lands. Hence the builder, wishing to make the most of his site, not only soars into the sky, but also burrows into the earth. By the London Building Act of 1894, Government laid down certain regulations as to the height of houses outside the City proper. The Legislature, however, has not dealt with underground rooms, except when they are used for dwelling purposes. The main object of the paper was to inquire whether underground rooms can be converted into wholesome workshops. The attention of the writers had been drawn to the subject by an investigation of underground bakeries. Most of these places are nothing more or less than cellars, and quite unfitted for workmen. In London, and no doubt in many of the large towns throughout the United Kingdom, many cellars and basement rooms are quite as improperly used as workshops. Until a rigid system of house-to-house visitation is the rule, it seems likely that 99 out of every 100 underground workshops will escape any control altogether. After careful consideration, the writers have come to the conclusion that an ordinary cellar can be converted into a wholesome workshop. It is true that such a task would involve a good deal of structural alteration and a considerable outlay of money. Among essential points of construction are a height of 8ft. and minimum of 500c.ft. for each workman, with a special allowance for gas-jets. Walls must be smooth, and kept dry by damp-proof courses and by freedom from contact with outside soil. The window-space must equal at least one-eighth of the floor area. Ventilation and light, as well as drainage and lavatory accommodation, must be such as to satisfy advanced modern requirements. The floor must have at least 9in. of concrete, and any drains passing beneath it must be laid at least a foot deep, and cased in a bed of concrete. Water should come from the rising main. In order to make a wholesome basement workshop, the writers regard a front outside area as absolutely essential. Further, they would make a second area compulsory, either at the back or the side of the building. The main practical difficulty in satisfying these requirements would, no doubt, be the making of an area in houses which rise flush from the pavement. In order to meet this objection, the writers have devised the scheme of the "borrowed area." The front of the shop is to be carried back some 5ft. or 6ft., and an area sunk in the space thus "borrowed," as it were, from the overhanging main building, which is supported by a cross-girder. The outside area is thus gained at the expense of a part of the shop and of the basement. The size of the shop is thereby lessened; but, by way of makeweight, the basement beneath is converted into a light and habitable room.

OBITUARY.

Mr. George Knowles, F.R.I.B.A., formerly in practice at Bradford as an architect and land agent, died on Friday last at Moorhead House, Shipley, Yorks, in his 81st year. He was for many years the head of the firm of Messrs. Knowles and Wilcock, in Leeds-road, Bradford, his works including the Town Hall at Guisely, the Institution for the Blind at Bradford, Westgate Ragged Schools, and Manningham National Schools. He had been a life member of the Royal Institute of British Architects since 1862.

CHIPS.

The cabinet works of Messrs. Walter and Jame Reilley, situate at Bardsley, near Ashton-under-Lyne, were destroyed by fire on Thursday night in last week, the damage being estimated at over £10,000. The works, which have not long been established, found employment for several hundred workpeople. The building was only partially insured. The origin of the fire is unknown.

At the Elton Fold Mills, Bury, Lancs, on Wednesday week, the mill chimney, which was 147ft. in height, was brought to the ground. Mr. William Fish, of Bury, was the contractor. The brickwork of half the base of the chimney was removed for a height of 2ft. 3in., and props were placed underneath and surrounded by a quantity of inflammable material. This was ignited, and after the fire had been burning for 34 minutes the props gave way and the chimney shaft fell, clear of all surrounding structures and people.

The new county hotel at Canterbury was formally inaugurated on Saturday night. It has been built from plans by Mr. William J. Jennings, M.S.A., of that city, Mr. J. J. Wise, of Deal, having been the contractor.

The Hampshire Field Club made an excursion to the Isle of Wight on Thursday in last week, when the parish churches of Calborne and Swainstone, near Freshwater, were visited.

A peal of eight bells are being hung this week in the belfry of St. Richard's Roman Catholic Church, at Holbeck, near Leeds. The bells have been cast by Mr. M. Byrne, of Dublin, and are said to be the first peal ever cast in Ireland for an English church.

The foundation-stones of a new Sunday-school, attached to the Primitive Methodist Chapel, Dudley-road, Wolverhampton, were laid on Saturday. The new building will be 58ft. in length and 30ft. in width, and will be provided with four classrooms. The total cost is estimated at £750.

A new infant school is being erected at Cadham, Hants, by Mr. C. Barter, of Shirley, from a design by Mr. S. Kelway Pope, of Southampton.

Mr. J. Hobson Matthews, the architect employed by the Cardiff Corporation, presented to the committee yesterday a further report on the records of the town. It stated that he had made copies of 19 charters and old records at the Custom House, dating back to 1683, and also of MSS. belonging to a gentleman at Carmarthen. He had, moreover, examined a large number of wills at Llandaff, dating from 1503 to 1750. The town clerk said he had requested Mr. Matthews to classify the information with a view to its being printed.

The new High Pavement higher grade board school at Stanley-road, Nottingham, was opened by the Mayor last week. The cost of the building, which is said by the local journals to be the most completely equipped for educational purposes of all the board schools in the country, was £10,528 0s. 6d., exclusive of fittings. It will accommodate 588 scholars.

On Thursday in last week foundation stones of a Wesleyan chapel at Strensall, near York, which is to replace a structure burnt down some months ago, were laid with due ceremony. The plans were prepared by Mr. Edward Taylor, York, architect. The accommodation in the chapel is about 120, and in the schoolrooms 70 sittings. The contractors are Mr. H. Creaser, of Strensall, and Mr. G. Mansfield, York.

ILLUSTRATIONS.

THE CORN EXCHANGE, GLASGOW.—THE HALL OF THE GROCERS' COMPANY.—LLANDAFF CATHEDRAL.—RICHMOND SECONDARY SCHOOL AND TECHNICAL INSTITUTE.—NEW WESLEYAN SCHOOLS AND CHAPEL AT HULL.—TOMB OF BISHOP BRIDPORT, SALISBURY CATHEDRAL.

Our Illustrations.

CORN EXCHANGE, GLASGOW.

The site is at corner of Hope and Waterloo-streets (opposite Central Station). The original building was erected 60 years ago. The site now being valuable, the directors are reconstructing and adding to the Exhaust, so that it may be utilised to the greatest advantage. The street floor will be occupied by the Royal Bank of Scotland and others. On the first floor is the exchange, news, and secretary's rooms. The upper floors will be let for offices. The work is now in progress, and will be completed in May, 1896. The stone is from Locharbriggs Quarries, Dumfries. Mr. W. F. McGibbon is architect.

CITY GUILDS: NO. X.—THE HALL OF THE GROCERS' COMPANY—THE DRAWING-ROOMS.

We need not describe the work shown by the accompanying double-page plate at any length, seeing that already an account of the new hall buildings has appeared in our pages this year, on which occasion we illustrated the staircase (on Jan. 25th), and the fireplace in the staircase hall figured in the Building News for March 22nd, when a plan furnished by the architect, Mr. H. C. Boyes, was published in further illustration of the work. By a reference to this plan the position of the two handsome drawing-rooms, now represented, will at once be seen. The chimneypieces are executed in alabaster and marbles, very richly treated. The figure frieze by Mr. G. Seale (who did the beautiful carving on the staircase) makes a conspicuous feature in the rooms, and the wall-panelling is in oak. The furniture is uncommonly rich, in the finest silks and Genoa velvet. This was made by Messrs. Holland and Messrs. Gillow. Our illustration is produced from a photograph specially taken for this series by Mr. J. T. Sandell, using his patent plates and a lens by Ross.

LLANDAFF CATHEDRAL.—R.I.B.A. MEDAL DRAWINGS.

We complete to-day our series of reproductions of Mr. J. H. James's prize Medal of Merit set of measured drawings of this well-known church, which is the leading cathedral in Wales. Last week we printed a detail sheet illustrating the west front. The plan, with view and other geometrical drawings, will be found in the Building News for July 12th, when a description appeared, so that the accompanying south elevation and longitudinal section need no further reference in this place.

SECONDARY SCHOOLS AND TECHNICAL INSTITUTE, RICHMOND.

The Duke of Cambridge last week laid the foundation-stone of these schools, which are to occupy a prominent site on the corner of Kew-road and Selwyn-avenue, and are being built from the designs of Messrs. Fryer and Bath, architects. The plans were selected in public competition, and unanimously adopted by the Richmond Technical Instruction Committee and the Surrey County Council. The plans provide for a large hall at the corner of Selwyn-avenue, capable of accommodating 300 persons, behind which will be a classroom for dress-cutting and provision for cookery classes, with separate entrance to this department. A large corridor will separate the main building from the hall, so as to prevent any annoyance or disturbance of the classes. The opposite wing will contain a classroom, 60ft. by 25ft., and is divisible into three smaller rooms by means of removable partitions. In the main building, on the ground floor, there will be two large classrooms, several smaller rooms, and accommodation for the head master. Behind the large classroom will be a well-equipped chemical laboratory and balance-room. On the first floor is the art school, 40ft. by 25ft., with an art classroom adjoining, and an art-master's room attached. On the same floor are other classrooms and caretaker's apartments. In the basement will be rooms for engine, boiler, coals, stores, and lavatories, &c. The building will be heated by hot-water radiators, and the ventilation will be specially provided for. The front elevation is of brick, with stone dressings. The original estimate for the building was about £5,500; but various modifications and additions have been made in the plans, including mosaic pavements to the corridors, &c., which will bring the approximate cost of the building to about £6,000.

NEW WESLEYAN SCHOOLS AND CHURCH, ANLABY-ROAD, HULL.

The above illustration represents Wesleyan schools now in course of erection on the Anlaby-road, Hull, with proposed church to be built hereafter adjoining. The schools, which will be opened on the 17th inst., are built in red stock bricks with terracotta facings from Messrs. Edwards and Co., of Ruabon. The building is arranged to accommodate 900 scholars with central hall, and 19 classrooms, library, infants' school, &c. The total cost of the schools is about £3,000. They are from the design of Mr. W. Alfred Gelder, F.R.I.B.A., of Hull.

BISHOP BRIDPORT'S TOMB, SALISBURY CATHEDRAL.

There is nothing in Salisbury Cathedral more interesting than this beautiful tomb, which is built in the form of a shrine, and exhibits foliage of the most refined character. The south elevation is similar to the north, except of course the spandrel reliefs which are shown on the drawing and interpreted by Mr. C. A. Stothard. On the south side the first shows a female figure with an infant lying on a bed, which may indicate the Bishop's birth. The second shows a figure kneeling before another figure, representing his confirmation. The third shows a figure clerically habited sitting at a high desk, reading to four youthful figures. In the fourth stand two clerical figures, apparently joining hands; one has a cap, and is more dignified than the other: behind is a tree from which a shield is suspended bearing argent a cross between four pellets or bezants or. Probably this relief represents his first preferment; this seems to be corroborated by the first spandrel on the north side, which shows two figures, one in a gown sitting, and the other inclining towards him with both hands extended as if in the act of doing homage for his see. The second shows a procession, the hindermost figure with an uplifted cross, which probably alludes to the consecration of the church by Bishop Bridport; and his death is shown in the third spandrel, extended on a bier, pontifically habited, with angels at his head and feet. The fourth spandrel shows a dignified figure pontifically habited, but without a crozier, enthroned in a niche, sitting as in judgment, in front of which is a naked figure borne up by an angel with wings expanded, which evidently represents the ascent of the soul to heaven. On either side of the head of the recumbent effigy are two angelic figures offering incense. The hands are gloved, the right giving the benediction, and the left holding the crozier. The battlemented canopy over the head bears a strong resemblance to the lower part of the tower immediately over the roof, which probably indicates how far the work had advanced previous to its dedication in 1258.

D. F. Smith, A.R.I.B.A.

COMPETITIONS.

Durham.—The competition for the new County Council buildings at Durham has now been settled, and the design marked by the motto of "Demos" has been adopted for execution at a cost not exceeding £22,000, the architects being Messrs. Harry Barnes and Fredk. E. Coates, AA.R.I.B.A., of Sunderland. The referee, Mr. MacVicar Anderson, last May awarded these gentlemen the second premium, and the first premium was voted to the plan inscribed "Onward" by Messrs. Cooksey and Cox, of the Adelphi, W.C.; but the conditions of the competition required substantial and *bonâ fide* tenders within the amount stipulated, to be submitted for approval before the council would confirm the adjudicator's recommendation. The quarterly meeting of the County Council was held during the past week, when the second premiated plans were brought forward by the Finance Committee for final adoption, and agreed to. The tender for building this design by Messrs. Barnes and Coates was stated to be £18,051, which was accepted, leaving a margin, as above stated, of £4,000 for contingencies. The tender for Messrs. Cooksey and Cox's plan amounted to £21,977, with only £23 for contingencies. It was stated at the meeting that the site in Old Elvet cost £6,000, and that the fittings and furnishings would bring the total cost up to £40,000. The work will be proceeded with at once, and we have arranged to illustrate the selected design at an early date.

Farsley.—The Calverly and Farsley School Board, at their meeting on Monday night, decided to invite five architects to send in sketch plans and estimates of a new school, consisting of central hall and five classrooms, capable of accommodating 360 scholars.

Gateshead-on-Tyne.—For the new permanent church of St. George, in the populous and rapidly-growing parish of Christ Church, Gateshead, designs were recently invited from five architects practising in Newcastle. The assessor, Mr. J. W. Walton-Wilson, F.R.I.B.A., of Shotley Hall, selected that submitted by Mr. Stephen Piper, M.S.A., of County Chambers, Westgate-road, Newcastle, and he has since been appointed architect. The whole scheme is to be carried out at once, inclusive of tower. The design is Early English in style, consisting of nave and aisles lighted by triplet lancets, no clerestories being introduced; shallow transepts, each having double gabled fronts and chancel; tower, with belfry and saddleback roof, on south side of west front, at angle of two thoroughfares. Accommodation will be provided for 630 persons. The contract has been let to Mr. Alexander Pringle, of Gateshead, at £5,900, and Mr. John Richey is the clerk of works.

Watford, Herts.—At a meeting of the School Board held on the 22nd ult., the design submitted by Mr. C. P. Ayres, of Watford, architect, was selected for the new schools to be erected in Fearnley-street, on land recently purchased from the Earl of Essex. The schools are to accommodate 1,020 children, and, including central halls and boundary walls, the approximate estimate is £10 per head.

CHIPS.

The Bishop of Wakefield dedicated, on July 24, a new vestry and chapel, which have been erected in connection with Sandal parish church, near Wakefield. Messrs. Denholme and Co., Wakefield, were the contractors.

New waterworks are being constructed at Heckington, for the Sleeford Rural Sanitary Authority. Mr. G. H. Williamson, of Sleaford, is the contractor.

The will of Mr. William Stenning, of Redhill, Surrey, timber merchant, has been proved, the personalty amounting to £19,101.

During a thunderstorm on Tuesday week, the Belle Vue Church, West Hartlepool, was struck by lightning, and the tower fell with a crash. Some men standing near had narrow escapes from the falling débris.

The opening of the new Church Sunday-school at Lanivet took place on July 24th. The school stands nearly opposite the rectory, and is built of Reperry stone, with coigns of Cardinham granite. The architect is Mr. Grose, jun., of Bodmin, and the contractors are Messrs. Ham Bros., of Bodmin, for masonry, and Mr. Tinney, of Lanivet, for carpentry.

Building Intelligence.

Berkhamsted.—The new chapel at Berkhamsted School, the foundation-stone of which was laid about a year ago, was dedicated on Saturday by the Bishop of Colchester. The building is constructed of red brick, with the windows and facings of white stone. The style is Late Perpendicular. The east end is designed after the church of Santa Maria dei Maracoli, at Venice. The Holy Table stands on three polished steps of Devonshire marble, and is approached by a broad staircase of dark blue Forest of Dean stone, with 15 steps. The chapel has been so constructed that its ornamentation may be gradually completed, the cost of the work having been already promised in several instances. The electric light is used, as throughout the school. The architect is Mr. Charles H. Rew, of Berkhamsted, and the builder Mr. Osborn, Berkhamsted.

Burnham, Somerset.—The contract has been let for the erection of a coffee tavern at Burnham, Somerset, for Mr. J. B. Braithwaite, jun., on the site of the Masons Arms Hotel. The premises will comprise a large coffee bar, bar parlour, manager's residence, accommodation for daily visitors, cyclists, football teams, &c.; also a suite of rooms for the Local Liberal Association. Messrs. Clark and Moscrop, of Darlington, are the architects, and Mr. James Keats, of Burnham, the contractor, who will carry out the work under the local superintendence of Mr. C. S. Leech, architect, of Burnham and Highbridge. The walling will be built of bricks made by the Apex Tile Company, with Corsham stone dressing, and the roof of Staffordshire Broseley tiles.

Coxlodge, Newcastle.—The foundation-stone of the extension of the Newcastle City Lunatic Asylum was laid on Wednesday afternoon, adjoining the present asylum at Coxlodge, near Gosforth, which was built in 1854, and enlarged in 1866. The architect is Mr. John W. Dyson, of Grainger-street, Newcastle, whose design was selected from 22 submitted in competition by local architects. The extension is being erected for male patients, and will accommodate 361, and when completed, the whole of the present asylum will be adapted for women patients, the total accommodation being then about 800. The new buildings are arranged in two-storied blocks, the various floors forming wards for the different classes of patients. The walls externally will be of stone, and the roofs covered with Bangor slates. The patients' blocks will have the floor between ground and first story of Mark Fawcett and Co.'s system of fireproof flooring, and the ceiling to the upper floors will be formed of concrete. The floors and woodwork generally will be pitchpine. The lavatories, bathrooms, &c., will be lined with glazed bricks. All the staircases will be of Yorkshire stone. The heating and ventilation will be on the "plenum" system, and all apparatus is to be in the subways below the buildings, so that no part can be interfered with by patients. There will be fire main services both inside and outside the buildings. In addition to the patients' blocks, there is a complete administrative department, comprising committee-rooms, offices, kitchens, stores, dining-hall, workshops, bakery, visitors' room, club-rooms for attendants, and apartments for the medical and other officers. There is also a new laundry, isolation hospital, recreation hall, chapel, superintendent's residence, head attendant's house, ten cottages for attendants, and entrance lodge. The buildings will be lighted by electric light, and the motive power required for driving machinery and ventilating fans will be electric. A complete electric plant is to be provided. The foundations and the erection of the main buildings to the ground-floor line have been carried out by Mr. John Ferguson, of Newcastle, and the contract for the superstructure and auxiliary buildings has been let to Mr. Walter Scott, of Newcastle, who is now proceeding with the work. The heating and ventilation will be carried out by Messrs. Ashwell and Nesbit, of Newcastle and London; the electric-light fittings, wires, and cables by the Corlett Electrical Engineering Co.; and the sanitary fittings throughout are to be of Doulton's manufacture.

Goathland.—On Wednesday week the new church of St. Mary at Goathland was consecrated by the Archbishop of York. The old church, which was built in 1821, had become so dilapidated that it was barely safe, and it was inadequate in size. The site of the new building, near to the old church, has been given by the Duchy of Lancaster. The church consists of nave, 52ft. by 22ft., chancel, 32ft. by 19ft., vestries, and south porch; it is built of local stone, which has been obtained free of cost from the quarries on the estate of Mr. McEacharn. The church will accommodate about 300 persons. It is designed in the Late Decorated style, treated in a simple and broad manner, characteristic of moorland buildings, with long lights. The tower has not yet been constructed. The architects are Messrs. Brierley and Demain, of York, and Mr. Barnes, of Malton, is the contractor. The special gifts include a lectern, the choir-stalls of oak, and an altar-piece. The cost of the buildings, which we illustrated in our issue of July 27, 1894, has been about £2,200.

Llanfairfechan.—A convalescent home is about to be built at Llanfairfechan, in connection with the North Staffordshire infirmary at Hartshill, by the sons of the late Mr. Robert Heath, of Biddulph Grange. The site of four acres has an unobstructed sea view, and is protected from the easterly winds by the Penmaenmawr mountain. Messrs. Bower and Hall, of Nantwich, are the architects, and the contract has been let to Mr. J. Gallimore, of Newcastle, who this week has made a start with the preliminary work. The building will be erected of blue Penmaenmawr stone, with freestone dressings. On one side the sloping ground gives the building a basement floor, including which there will be four stories. The building will be 130ft. long, with a depth of 45ft. The basement will contain dining-hall, coming out level with the garden, kitchen, bagatelle-room, scullery, and domestic offices. The ground-floor comprises sitting-rooms, library, surgery, and matron's room. The upper floors will be occupied as dormitories and servants' quarters. Laundry and stables will be attached.

Waskerley.—The foundation-stone of a little moorland mission church was laid on Saturday afternoon. The church, which will be at an elevation of a 1,100ft. above the sea level, provides sitting accommodation for 100 persons, and will be substantially built of stone and covered with stone flags, both quarried on the moor adjoining. Messrs. Kidd and Son, of Cowshill, and Mr. Philipson, of St. John's, Weardale, are the builders. Messrs. Clark and Moscrop, of Darlington, are the architects.

CHIPS.

The Grosvenor Restaurant in John-street, Sunderland, was opened on Tuesday. It has been built from designs by Mr. Hedley, of that town.

At Tuesday's meeting of the Staffordshire county council it was resolved to raise the salaries of Messrs. Watkins and Fennell, assistant surveyors, from £175 to £200 per annum.

The death is recorded of Alfred Clarence Alais, engraver, in his 60th year. He reproduced some well-known cattle and other plates, after Edwin Douglas, of "Jersey," "Alderney," "Sark," "Evangeline," "Hern," "Jersey Beauties," "Ferreting," and "Mine Host." He also engraved "Home, Sweet Home," and "Hunter and Cob," after Landseer; likewise the popular pictures, after Stanley Berkeley, "A Disgrace to his Family" and "A Credit to his Family."

A new reading-room which has been erected at Springfield, Wolverhampton, under the bequest of the late Mr. Edward Butler, will be opened to-day (Friday). The premises consist of a newspaper-room, 32ft. by 23ft., and a magazine-room, 39ft. by 23ft., while adjoining is a caretaker's house. The total area on which the building stands is 520 yards, and the cost will be £1,000. The style is Domestic. Red brick has been used in the exterior part of the building, and the upper portion is finished in rough-cast and tile hangings with gables, while the roof is covered with red tiles. Pitchpine blocks have been adopted for the floors, and the whole of the interior woodwork is stained and varnished. Accommodation is provided for about 150 persons. Messrs. Bradley and Lloyd have erected the building, from plans prepared by Mr. Lavender, of Lichfield-street, Wolverhapton.

We inadvertently stated in our last issue that the architect for the new workhouse hospitals, Burnley, was Mr. G. Keighley. This is a mistake; the architect being Mr. Samuel Keighley, of Burnley.

M. Henri Blondel, a well-known architect and contractor, who has designed and constructed many of the best-known buildings and thoroughfares in Paris, was fined, on Monday, 3,000 francs on a bankruptcy summons. His liabilities were stated to amount to over one million francs.

Engineering Notes.

Southampton.—The new graving dock to be opened to-morrow (Saturday) by the Prince of Wales, who will be accompanied by the Princess of Wales and the Duke of York, has been constructed during the past two and a half years by Messrs. Lucas and Aird, who are also the contractors for the quay extensions at the same port. The graving dock is the largest in the world, and occupies a portion of the mudlands on the south side of the Empress Dock. It is 750ft. long clear on the blocks, 87ft. 6in. wide at the bottom, and 91ft. at the top, the coping level, and the depth 42ft. from the surface to the floor of the dock, while the depth of water will be 29ft. at high-water neap tides, so that a vessel drawing 28ft. 6in. can enter. It is built of Portland cement concrete faced with bricks, and the brickwork itself is faced with blue bricks. The altars, coping, caisson stop, and sluice faces are all constructed of Cornish granite. There are three flights of steps from the surface to the floor of the dock. It will be emptied by two 48in. invincible direct-acting pumps, built by Messrs. J. and H. Gwynne, of Hammersmith; they are capable of emptying the dock in from one and a half to two hours, throwing 500 tons or 112,000 gallons of water per minute, the estimated amount of water that the new dock will contain being $16\frac{1}{4}$ million gallons. The pumping station is on the east side of the dock, the chimney shaft being 120ft. high. There are six Galloway boilers, each 30ft. long and 7ft. 6in. diameter, to supply motive power to the engines, and for the hydraulic cranes which will be provided alongside the quays. There will be three hydraulic capstans for bringing ships into the new dock. There is also a Titan travelling crane lifting 30 tons, and built by Messrs. Stothert and Pitt, of Bath, who constructed the electric cranes at the Town Quay. Alongside the pumping station is a large shed for baggage 300ft. long by 40ft. wide. To form an entrance from the Empress Dock, 4,000 tons of solid concrete had to be removed, necessitating the use of gelignite for blasting purposes. Instead of the usual dock-gates at the entrance to the new dock there is an iron ship caisson, 95ft. long, 25ft. broad, and 45ft. deep, built by Messrs. G. Rennie and Co., of Greenwich. There have been nearly half a million cubic yards of Micheldever chalk used in making the banks in connection with the reclamation of the mudlands. About 100,000yds. of concrete, 44,000ft. of granite, and 6,000yds. of brickwork have been laid in the new graving dock. Over 20,000 loads of balk timber have been used in the general construction. Thirty-six thousand tons of Portland cement have been ordered, and 24,000 tons have been used up to date. The amount of excavations came to 214,000yds., 93,000yds. of that having to be done in timbered trenches, some of which went down between 60ft. and 70ft. below the surface of the foundation of the walls. The majority of the bricks came from Bishop's Waltham. In addition to the new graving dock, about 600ft. of the east or Itchen quay has been completed, the new work covering an area of about 10 acres. Alongside this quay is a depth of 28ft. at low water of spring tides. The quay is to be continued, to make altogether a length of 1,600ft. It will then return for 420ft., and join the south-west or Test quay, which will be 1,500ft. long. The mudlands have been inclosed with a chalk bank preparatory to building the wall. The whole area eventually will be filled up between these walls to the same level as the rest of the dock work, and will be available for railway-sidings, sheds, &c. Six dredgers have been used in deepening the channel of the harbour to a depth of from 28ft. to 30ft. at low-water spring tides. The work has been carried out under the superintendence of Mr. Wm. Colson, A.M.I.C.E., agent for Messrs. Lucas and Aird, and Mr. M. F. Wilson, A.M.I.C.E. watched the work on behalf of Messrs. Galbraith and Church, engineers for the London and South-Western Railway Company.

The Duchess of Teck unveiled, on Tuesday, a bust of Sir T. Whittaker Ellis, which has been placed in the Richmond Town-hall. On the pedestal it is stated that Sir Whittaker Ellis was Lord Mayor of London in 1881-82, M.P. for the Kingston division of Surrey from 1884 to 1892, donor of the site of the Richmond Town-hall and grounds in 1890, and first Mayor of Richmond 1890-91. The bust is the work of Mr. F. J. Williamson, of Esher.

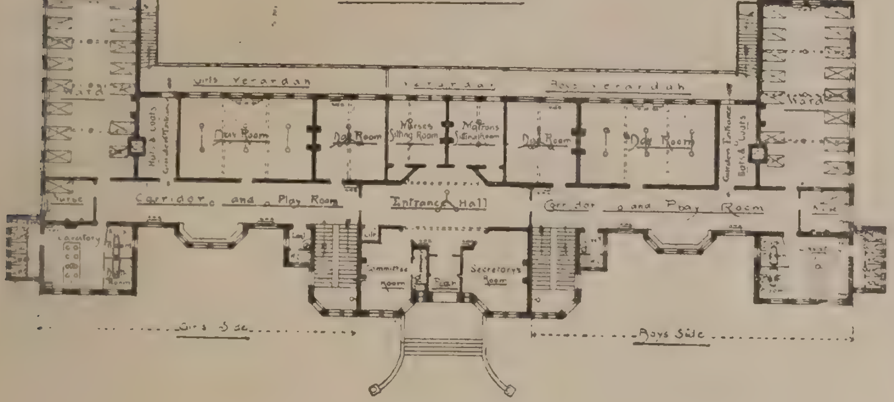
First Floor Plan



Ground Plan

THE YARROW HOME (BROADSTAIRS) FOR CONVALESCENT CHILDREN.

THIS building was opened last Wednesday, the 31st ult. It has been erected from the designs of Messrs. Davis and Emanuel, the architects, whose plans of the principal floors we herewith illustrate. In considering the best direction in which to devote a large sum in the most useful manner for the benefit of children, it was felt that there are many people of very limited means and, at the same time, highly respectable, who, in times of adversity, suffer much privation. Assistance given to them, in the form of a seaside home for their children in weak health or recovering from illness, was deemed, after much thought, to be one of the best directions in which a large benefaction could be applied. Hence the erection of this new seaside home for the reception of children (50 boys and 50 girls) of deserving parents who are not in a position to supply to their convalescent children, entirely at their own cost, the advantages of a temporary residence at the seaside. As examples of the class from which it is expected the children will be derived, may be mentioned the minister of limited means, the unsuccessful professional man, the clerk with a small income but with the obligation of maintaining a respectable appearance, the struggling tradesman, and the skilled artisan or foreman, all of whom, from exceptional causes, may be in straitened circumstances. Children are eligible irrespective of nationality or creed, and they must be between four and twelve years of age. The institution is not to be used as a holiday resort; nor is it intended for children suffering from incurable complaints, nor for such as require active medical or surgical treatment, nor for those coming from a home where there has been any infectious or contagious disease; but only for such children as may be expected to derive permanent benefit from a stay at the seaside, where slight nursing supervision will be available. The building is surrounded by a large sheltered garden and faces the sea. It is believed to be one of the most complete in design and equipment yet erected. The situation and arrangement of the home will allow of its being kept open throughout the year.

It is proposed that a nominal weekly payment (5s.) shall be made by the friends of the children, the object of which is to make the home partly self-supporting, which, it is thought, will render the institution more acceptable to the class for whose benefit it is intended. It is estimated that the average duration of stay of each child in the home will be about three weeks, although the time may be extended. By special arrangement with the London, Chatham, and Dover Railway Company, tickets will be issued between London and Broadstairs at 1s. 9d. each way.

The trustees' London office is 73a, Queen-Victoria-street, E.C.

The land upon which the building stands is situated at the south side of Broadstairs, with a considerable frontage facing the sea, and has an area of 10½ acres, with ornamental grounds, kitchen garden and orchard, with direct access to the cliff. The site slopes considerably downward towards the sea. The building is designed to accommodate 100 children, viz.:—50 girls and 50 boys, with the working staff in addition. It fronts the Ramsgate-road, from which it is set back about 100ft., and at the entrance-gates is placed the porter's lodge. It occupies a frontage of 218ft., the depth at the wings being 76ft., and through the centre block 62ft. The general scheme of the design of the home is a central administrative block, with wings for the girls and boys respectively. The main entrance from the Ramsgate-road is on the centre line of the building. Access from it is given to a spacious octagonal hall. The matron's room, the nurses' sitting-room, the committee-room (with small dispensary attached to it), and the secretary's room are all entered from this hall, and occupy the central block on this floor. The wings on either side of the central block are separated therefrom by glazed screens, and each wing contains, on the upper ground-floor, a large day-room, 33ft. by 20ft.; a small day-room, 20ft. by 17ft.; a dormitory 45ft. by 22ft., for 15 children, with nurse's room adjoining; and a play corridor, 66ft. by 10ft., with a large bay window in addition. This 10ft. wide corridor is a special feature. An ordinary 5ft. wide corridor would serve all purposes of intercommunication; but, by widening it to 10ft. and laying its floors with noiseless wood blocks, the corridor becomes a valuable room in such a building. All rooms are 14ft. high in the clear. The children's day-rooms, the matron's room, and the nurses' sitting-room are on the sea-front and open on to a verandah 152ft. long and 6ft. 6in. wide, extending nearly the whole length of the building, from which ever-changing sea views are obtained. At each end of the verandah is a hat and coat-room, with bins for boots and shoes, and through this room the boys or girls, by means of a concrete staircase inclosed from the weather, obtain access to their respective covered playgrounds, and thence to the general garden.

The first floor contains in each wing, and entered from a wide corridor on the road front, a dormitory 45ft. by 22ft. by 18ft. high, with dormer windows, and with beds for 15 children; a dormitory 32ft. 6in. by 24ft. by 18ft. high, with dormer windows, and with beds for 12 children; a dormitory 24ft. by 23ft. by 14ft. high in the clear, and with beds for eight children: thus making (with the 15-bed dormitory on the upper ground-floor) the total accommodation for 50 children in each wing, viz., 100 children in all. The average cubical capacity in these dormitories gives each child something over 1,000 cubic feet. Each dormitory has a nurse's room adjoining, with inspection-window for supervision. There is a liberal provision of linen-closets and stores. The matron's and two spare bedrooms and bathrooms in the central block complete the accommodation on the first floor. The lower ground-floor contains the dining-hall, 64ft. by 27ft., situated under the central block, and is on the same level with, and opens on to, the garden on the sea-front. Separate access to this hall is given to the girls and boys by means of the two staircases. Adjoining the dining-hall is the serving-room, kitchen, and scullery, with the necessary store-rooms, linen-mending room, servants' hall, larders, cellars, knife and boot-room, &c. The rest of the lower ground floor is used for the boilers, heating apparatus, coals, engineer's shop, laundry, drying-closet, and general stores. At each end of either wing there is a covered playground supplied with swings and appliances for children's games.

The builders were Messrs. Colls and Sons. The materials for the walls are red brick, and the roofs are covered with Broseley tiles. The woodwork is painted white. No subscriptions are asked for, and the only help which will be acceptable is that the public will assist the trustees in securing cases worthy of the advantages of this capital home.

CHIPS.

Mr. Beall, sculptor, of Newcastle-on-Tyne, has just completed the erection, in Felling Church, of an alabaster tablet, with black marble inscription panel, to the memory of the late William Watson Pattinson, J.P., of Felling House. The design is by Messrs. Hicks and Charlewood, Newcastle, architects. The ceremony of unveiling the memorial will take place on Thursday in next week, the 8th inst.

The peal of bells at Uppingham parish church is being rehung and recast by Messrs. John Taylor and Co., of Loughborough.

Mr. H. Clarke, who has been engaged by the Morley Corporation as clerk of works for the new Town-hall and Municipal Buildings for the past three years, has been appointed to a similar position by the Harrogate School Board, for new schools.

The foundation-stone of the addition to the Town-hall at Lynn, now being erected by Messrs. Young and Co., of Norwich, according to plans prepared by Messrs. Tree and Price, of London and St. Leonard's, was laid by the Mayor on Saturday.

The bells of the Cathedral Church of Manchester, which had been silenced for over a year, were re-rung on Thursday in last week, having been hung afresh and refitted by Mr. Blackburn, of Salisbury.

The final section of the North Cornwall Railway, that from Wadebridge to Padstow, will be commenced immediately after harvest. The contractors for this section, which is seven miles in length, as for the previous portions, are Messrs. Curry, Reeve, and Co.; but the long iron bridge over Dennis Cove, near Padstow, has been taken by Messrs. Lucas and Aird, of London.

Mr. R. Deane Sweeting, an inspector from the Local Government Board, has held an inquiry at Kettering into an application from the rural district council for sanction to borrow £2,500 for a new fever hospital.

The foundation-stone of the additions to St. Edmund's Roman Catholic College, near Standon, was laid by Cardinal Archbishop Vaughan on July 23. The new buildings will, when complete, include an exhibition hall, which will be used as a study place, ten classrooms, lavatories, swimming-bath, covered playground, two dormitories, a library for the boys, and a billiard-room for the professors. The architect is Mr. A. E. Purdie. The part to be immediately proceeded with will comprise a swimming-bath, lavatories, and dormitory to hold 40 boys, and, if funds permit, additional classrooms and a boys' library. The estimated cost of the undertaking is £4,500.

Messrs. King and Leach, builders and contractors, of Rochester, have this week commenced the building of a new Coastguard Station at Calshot Castle, Hants.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

Glasgow Architectural Association.—The following are the office bearers for the eighteenth session of this association:—Hon. president, Mr. Malcolm Stark, I.A.; president, Mr. Alex. N. Paterson, M.A., A.R.I.B.A.; vice-president, Mr. Wm. Tait Conner, A.R.I.B.A.; hon. secretaries, Messrs. Walter R. Watson and Hugh Dale; hon. treasurer, Mr. George Hill, A.R.I.B.A.; hon. librarian, Mr. Alexander M'Gibbon, A.R.I.B.A.; general committee, Messrs. Wm. J. Anderson, A.R.I.B.A., George Copland, William Fraser, A.R.I.B.A., and Robert J. Gildard. The syllabus for the new session is as follows:—

August		Visit: Hawkhead Asylum, Crookston. Mr. Malcolm Stark, I.A., architect.
Sept.	3	President's Opening Address—"History, Archæology, and Art."
,,		Visit: Theatre Royal, Glasgow. Mr. C. J. Phipps, F.S.A., architect.
,,	17	Lecture, by Rev. David Watson, Woodside Church.
Oct.	1	Member's Paper—"Materials." Mr. Alex. M'Gibbon, A.R.I.B.A.
,,		Visit: Glasgow Art Galleries, Kelvingrove. Messrs. Simpson and Allan, architects.
,,	15	Lecture. Mr. Malcom Stark, I.A., Hon. President.
Nov.	5	Member's Paper—"Organ Building." Mr. Hugh Dale.
,,	19	Lecture. Mr. Percy Fitzgerald, M.A., F.S.A., London.
Dec.	3	Member's Paper—"Acoustics." Mr. Alex. M'Kee.
,,	17	Lecture. Mr. James A. Morris, F.R.I.B.A., Ayr.
1896.		
Jan.	7	Member's Paper—"An Architectural Aim." Mr. George Hill, A.R.I.B.A.
,,	21	Lecture, by Mr. P. M'Gregor Chalmers, F.S.A., Scot.
Feb.	4	Association Travelling Studentship. Essay, by Mr. George Gunn, A.R.I.B.A.
,,	18	Lecture, by Mr. John W. Simpson, A.R.I.B.A., London.
March	4	Annual Business Meeting.
,,		Smoking Concert.
,,		Visit: Somerville Free Church, Keppochhill. Mr. W. G. Rowan, architect.
April	1	Presidential Address. Opening of New Session.
,,		Visit: Ruchill Hospital, and Ruchill Disinfecting Station.
May	5	Prize Essay—"The Distinctive Qualities of Scottish Architecture."
,,		Day Excursion: St. Margaret's Church, Dunfermline. Dr. R. Rowand Anderson, Edinburgh, architect.
June	3	Member's Paper—"The Designing of Wall Papers," by Mr. Alexander Orr.
,,		Visit. Kilbirnie Church.

Sheffield Society of Architects and Surveyors.—The following is the programme for the ensuing session. The meetings, with one exception, that of March 11th, are held on Tuesdays:—Oct. 8th, opening meeting (conversazione), address by the president, Charles Hadfield, F.R.I.B.A.; Nov. 12th, "The Brotherhood of Architects," by Paul Waterhouse, M.A., F.R.I.B.A., London; Dec. 10th, "Norman Architecture," with limelight illustrations, by H. C. Sorby, LL.D., F.R.S., Sheffield; Jan. 14th, 1896, "The Adam Architecture," with eighty limelight illustrations, by Percy Fitzgerald, M.A., F.S.A., London; Feb. 11th, "Local Half-Timbered Buildings," by Thomas Winder, Assoc.M.Inst.C.E., Sheffield; March 11th (Wednesday), "Axiality," by Hugh Stannus, F.R.I.B.A., London; April 8th, annual general meeting.

* * *

Messrs. E. H. Shorland and Brother, of Manchester, have just supplied some more of their patent Manchester grates and stoves to the Normanton School Board for their schools at Normanton-common, those previously supplied having proved very satisfactory.

The Exeter Architectural and Archæological Society held a district meeting at Kingsbridge and neighbourhood on Wednesday week. Kingsbridge Church, with its fine spire, the abbot's grange at Churchstow, the great church at Dodbrooke, an unrestored church at Sherford, and the collegiate buildings and church at Slapton formed the chief features of an interesting day's excursion.

The Ecclesiastical Commissioners have offered to sell Churchyard Bottom Wood, Highgate, containing an area of 65 acres, to the district council for £25,000, and waive their right to cut two roads through it. By this the rural character of the Wood will be preserved, and the Charity Commissioners, who are giong to complete their scheme by selling the front for building purposes, will gain another 50ft. frontage, and enable two more houses to be erected upon the land, and thus £20 a year will be added to the prospective income of the charities. This scheme is understood to have the approval of the Charity Commissioners.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—Jas. Wilton.—Competitor.—E. D. S. and Co.—B. J. (Crewe).—Reg. Plumb.—E. T.

Assistant. (Please send; working drawings are always acceptable. There is no need at all for architects of ordinary buildings to go to the trouble and expense of making perspectives; we have dozens and dozens on hand. But sheets of working drawings of almost any work are always welcome.)

Correspondence.

CRAFTSMAN R.I.B.A.

To the Editor of the Building News.

Sir,—Now that candidates for Fellowship have the chance of being rejected because they are outside the art clique on the Council, or, if accepted, of being afterwards black-balled by the junior members, it cannot be wondered at that the supply of Fellows with their £4 4s. subscription is running short, and a new departure to obtain money seeems necessary.

We are to have, it seems, some intelligent workmen in the ranks who will be considered by the outside public to be much the same as other members.

What will the capitalist say if his practical manager is admitted to the style, rights, and dignity of Craftsman R.I.B.A., and himself left in the cold? Surely trouble in the family must follow.

The Hon. Associates are quite enough. I have known the opinion of one quoted against that of an ordinary member, and I hope that somebody among the young and energetic spirits of the profession will take steps to prevent this newest fad from becoming an accomplished fact, as another retrograde movement of the antiquated circle in Conduit-street. Let architects be architects, and let workmen, however artistic, be kept out of the fold.—I am, &c., Observer.

A BUILDING-LINE CASE.

Sir,—On page 139 of your last issue Mr. Wetherfield ably summarises the City-road case; but in the concluding paragraph he appears to think that the prevention of the building on the forecourt is a hardship to the owner.

The upper part of the City-road on both sides is a wide thoroughfare; the houses are set well back, with a long garden in front, and it must be obvious that a wall 11ft. high would quite spoil the appearance of the road, and be a great hardship to the adjoining owners.

This is a very important decision, as I felt it would be when I reported it to the superintending architect.—I am, &c.,

314, Old-street, E.C. Henry Lovegrove.

THE ARCHITECTURAL PROFESSION IN THE NORTH OF ENGLAND.

Sir,—It is not in the North of England alone, but all over the kingdom, and even in London, that architectural quacks abound.

I noticed in your columns the other day the name of an unsuccessful speculative builder, and the name of a builder's clerk in a well-known firm, both figuring as architects of important jobs; and I saw the other day some plans bearing the name of a man who eight years since was a bricklayer.

Some system of registration is necessary.

I have also seen quantities prepared by architects with items as vague as those described by "An Old Subscriber."—I am, &c.,

Surveyor.

CHIPS.

The failure of sales of large estates and residential properties of magnitude has been a consistent feature of the season at the Auction Mart, and last week proved no exception to the rule. The general tone of business, however, was very firm, as far as sound investments are concerned, the aggregate realisation amounting to £204,901.

A music hall at Broadmead, Bristol, was reopened on Monday night after reconstruction and redecoration from plans by Mr. Hancock, architect, of Bristol.

A destructive fire occurred on Friday morning at 5, Coleman-street, E.C., upon the premises of Messrs. Colls and Sons, builders. The building consisted of four floors, 50ft. long and 30ft. wide, which were used as workshops. The flames suddenly burst forth in the upper floors of the structure, and rapidly spread to a second building of three floors, 90ft. long and 30ft. wide, used as showrooms, offices, and workshops. The workshops were eventually gutted, but fortunately the office portion was saved.

At Friday's sitting of the Chester Consistory Court, Chancellor Espin granted faculties as follow:—For a new roof and other alterations to Bruera Church, at a cost of £2,500; for the erection of a tower at St. Chad's Church, Tushingham, at a cost of £1,000; and for several alterations at St. Bridget's with St. Martin's, Chester, at a cost of £500.

A racy letter by Mr. Harry Hems, of Exeter, descriptive of his voyage to the Canaries *en route* for the Cape, appears in the *Exeter Evening Post* of Tuesday.

In the applications for discharge from bankruptcy made in the case of Owen Jones, of Liverpool, builder, the discharge has been suspended for two years, ending June 21, 1897.

The Johannesberg Consolidated Investment Company have purchased the freehold property, Nos. 10, 11, and 6½, Austinfriars, E.C., which covers an area of 5,000ft. super., and have instructed Mr. T. H. Smith, of 17 and 18, Basinghall-street, to prepare plans for the rebuilding of same for their occupation.

Mr. Andrew Carnegie has offered to bear the cost, estimated at £2,500, of building a library at Wick, N.B., provided £1,200 can be raised otherwise as an endowment.

Another step in the direction of establishing a suitable central fire-station in Liverpool was taken on Tuesday, when a Local Government Board inspector received evidence regarding an application to borrow £35,000 for the purpose.

A stained-glass Tullis memorial window presented to Greenhead Parish Church, Glasgow, has just been completed by Mr. Stephen Adam, St. Vincent-street, Glasgow. The lower portion of the window, which is a three-light one, represents the Adoration and the gifts of the Kings, and the lower part represents Christ in Glory surrounded by worshipping figures.

The new Anglican Church at Grindelwald was opened on July 25th. The building has been erected on the site of the first church (destroyed by the great fire of 1892), which was built by the late Canon Butler. His friends have presented the new church with a pulpit and reredos in his memory.

Intercommunication.

QUESTIONS.

[11385.]—**Board School.**—Will some reader kindly give the name of the best book on School Architecture, especially as regards central halls, cookery, and manual training centres? Must be up-to-date.—Provinces.

[11386.]—**Cost of Floors per Square.**—Will a practical reader of the Building News inform me what would be about the cost per square of a floor over shop constructed with rolled joints, with concrete or fireclay between, having 1½in. deal floor and lath and plastered ceilings? Also price of same with ordinary joints.—In Doubt.

[11387.]—**Fresh Air Required Per Hour.**—What is a fair allowance of pure air per hour in a room to maintain a standard of purity? Is there any difference between the quantity to be supplied for a large room and a small one per head?—T. R.

[11388.]—**Interior Woodwork.**—Is planed deal, unstained and unvarnished, as durable as if stained and varnished for roofs?—Young Builder.

[11389.]—**Schools.**—Would anyone kindly give the names of towns in England and Scotland, in which the best, most modern, and improved examples of schools could be seen, as also the best systems of heating and ventilation?—Quartz.

[11390.]—**Sketching Tour.**—Will some reader kindly give a list of places of architectural interest between Dartford, Rochester, and Maidstone, Kent, with notes as to buildings worthy of study, which could be seen in about a fortnight? Gothic work would be preferred.—Pedestrian.

REPLIES.

[11365.]—**Law of Light.**—Roscoe, in his "Digest of the Law of Light," says:—"The grant of a servient tenement over which light comes to a building, both being the property of one owner before such grant, gives the grantee of the servient tenement the right to prevent the right to light from accruing to such building, whether it remains in the possession of the grantor, or is subsequently transferred to another person, unless the right is reserved by the deed of grant, and until an enjoyment of the light has continued for 20 years." I believe this quotation will be an answer to "Lex." The grantee of the servient tenement has therefore the right to prevent the light coming to a building originally lighted under these circumstances, unless the right has been reserved by deed. Wheeldon v. Burrows is cited as an example.—G. H. G.

[11367.]—**Width of Ward Floor.**—A width of 24ft. is a good breadth for a ward. In the design for new sick hospital at Hendon the wards are of this width, and are intended for 28 beds. (See plan given in "B. N.," June 21.) The warming may be Galton's open-air stoves with the flues arranged in the side walls. These may be supplemented by radiators placed under windows, the fresh air being made to pass through these into wards.—G. W. G.

[11368.]—**Papering Front Hall.**—The most artistic pattern for a hall is one in which a more or less conventional arrangement of foliage is followed. There are many suitable patterns of paper sold by Jeffrey and Co., Essex-road, Islington, or Woollams and Co., Manchester-square.—G. H. G.

[11371.]—**Water-Colour.**—Several useful treatises and manuals are published. Those published by Messrs. Rowney and Co., Winsor and Newton, Reeves and Son, are useful guides. I have found those in Winsor and Newton's series serviceable, and the lists of colours and tints are of value, always remembering that where a natural aptitude to perceive colours—or instinct, if we like to call it—is absent, books or lists of this sort are of little value. Some very useful advice is given in Prout's "Hints on Light, Shadow, &c.," Pyne's "Rules," Penley's "Manual," in one of the above series. With a natural perception for colour and the use of a colour-box, anyone may soon be able to acquire the necessary knowledge of mixing colour. The preparation of the paper or surface, method of laying on the local tint or the washes are easily learned from one of the above books, or from a few lessons at any school of art in the locality.—G. H. G.

[11375.]—**Northamptonshire Churches.**—Northamptonshire is, *par excellence*, a county of churches. "Bicyclist" can do a great deal on his machine by taking cross and by-roads to some of the finest churches. Of a few of the more ancient examples, I may mention the Saxon tower at Earl's Barton, one of the typical specimens of the style. It has been crowned by a 14th-century embattled parapet. The tower, in four stages, has a decided batter, and the walls are divided into panels by pilaster strips and the long-and-short work at the corners. All Saints, Brixworth, with western tower and octagon spire, is an interesting church, having traces of Roman, with Roman bricks. In Northampton, the Church of the Holy Sepulchre is a good example of a circular church, crowned by an octagonal clerestory and roof, with a massive square tower (14th century) with angular buttresses and an octagon spire. The round nave (Norman) has chancel aisles of the same style, and partly decorated. The central part has a cupola carried on eight round pillars, disposed in a circle. From them spring pointed arches. The octagonal clerestory is supported on these. St. Peter's, Northampton, is a good example of Norman. The tower has enriched Norman arcading in the middle stage in two tiers, and the later upper story has an embattled parapet of 14th-century character. It is a very beautiful specimen of the style. A characteristic feature of the churches of this county is to be found in their towers and spires. These are generally at the west end, plain and massively treated, usually broached. Of Early English spires, that of Ringstead Church is a good example of a broached spire. This church has also a square-headed narrow lancet with a cusped tympanum. I may also mention the fine tower and spire of Warmington Church, with a broach spire and three tiers of dormers. Kettering, a noble example; Strixton, Finedon, Geddington, Clapthorn, Moreton Pinckney, Polebrook, Raunds, Oundle, &c., have interesting features. The Northamptonshire churches are famous for their Decorated roofs, as that at the fine church at Raunds. A full account of the churches visited in this district by the A.A. has been given in the Building News.—G. H. G.

[11384.]—**Damp Floor to Cellar.**—From a description of the cellar given by J. Feacey, there must be something wrong either with the drainage or the cement concrete floor. The surface drainage cannot be deep enough, or the drains sufficient. Of course the blue clay, being impermeable, prevents the surface water from escaping below its level. If there had been an outlet through the clay, the water could have got away. Method 1: I should recommend "J. F." to break up the floor, and put in a deeper drain; also to fill the hollow wall with the "Hygeian rock composition," or, preferably, build another 4½in. wall all round, with an inch cavity between it and the present outer walls, and fill it with this composition. The present floor should also be covered with the "composition," connected with the wall linings through the course at the floor level, and then be relaid with tiles in cement. Method 2: If less radical measures are desired, line the walls with the "Hygeian composition" to the level of the ground outside, and put down on the present floor a hollow tile floor filled in with cement concrete, and cemented to a fine face. I have known this done with good results. "J. F." says: "In dry weather the floor becomes covered with moisture and dampness." This is probably due to condensation of the moist air, and can be obviated by ventilating the cellar, for which purpose an inlet tube should be provided from the external air, and a flue carried up opening into one of the chimney flues. Method 3: If there is any opportunity, the evils complained of may be removed by forming a dry area outside, on one or more sides of the cellar, with perforated bricks between the area and the cellar. This would be the best kind of ventilation. Tile drains laid along the bottom of this, and below the floor level, would remedy the evils.—G. H. G.

CHIPS.

At Treharris, Merthyr Tydvill, on Monday, Mrs. Frederick Harris, the wife of the chairman of the directors of the Harris Deep Navigation Coal Company, laid the foundation-stone of a new church dedicated to St. Matthias. The architect is Mr. J. E. Pearson, R.A., and Messrs. Cowlin and Son, of Bristol, are the contractors. The new edifice will cost £3,500, and seat 350 people.

Viscount Cross has been elected the Master of the Clothworkers' Company, and Dr. John Samuel Phené, F.S.A., F.R.I.B.A., has accepted office as one of the wardens.

Chancellor Oliphant held a special sitting of the Constitutional Court of St. David's Diocese at Carmarthen, on Wednesday, to hear an application for a faculty to pull down Swansea parish church and erect a larger one in its place. It was explained that the accommodation of the present church was inadequate, and it was intended to erect, from the designs of Sir Arthur Blomfield, a church with 1,200 sittings, at a cost of £20,000, of which £15,000 is subscribed. The faculty was granted.

A special service was held at Lichfield Cathedral on Wednesday, when the Bishop of the diocese reopened the Lady-chapel and dedicated numerous offerings for its use and adornment. The gifts represent an outlay of £4,000, and are quite independent of the fabric fund.

The foundation-stone was laid on Wednesday of a new church at Great Saughall, near Hawarden. It is being built from the designs of Mr. Medland Taylor, of Manchester, and will be mainly of brick, with tiled roof.

On Wednesday week a small party of members of the Birmingham and Midland Institute Archæological Section visited Bolsover Castle, and a fine Elizabethan house at Barlborough.

Lord Wodehouse was convicted at Smallburgh, Norfolk, on Tuesday, of having assaulted Mr. John Gaymer, a well-known builder, at North Walsham, during an open-air election meeting on the 17th inst., and fined £5, including the costs.

An interesting event occurred on Friday last on Easby Hill, Great Ayton (one of the highest points of the Cleveland Range), when Mr. J. Havelock Wilson, M.P. for Middlesbrough, declared the completion of the restoration of Captain Cook's monument, erected in 1827. It is the only monument erected in this country to the memory of "England's greatest sailor," and had become very dilapidated, the inscription having grown almost illegible. The monument has been pointed with Portland cement, the door blocked up, a lightning conductor fixed, a grey granite slab containing the inscription inserted in place of the metal plates, and a palisading put round the base. Mr. G. Grierson was the contractor.

The monument erected in York Minster to the memory of the late Archbishop Thomson will be unveiled on Friday in next week, the 9th inst. The ceremony of unveiling will be performed by the Earl of Crewe, late Lord Lieutenant of Ireland. The monument consists of a recessed altar tomb, designed by Mr. G. F. Bodley, A.R.A., with a life-sized recumbent effigy by Mr. Hamo Thornycroft, R.A. The site of the monument is in the south transept, just outside the entrance to the south choir aisle.

Legal.

HOUSE WARRANTY.

Upon the letting of an unfurnished house there is in law no implied warranty whatever that it is fit for the purposes of its occupation. This point has been decided over and over again, and it is only where an express warranty, either written or verbal, has been given as to drainage or the like that damages can be recovered; but in the case of a furnished house a different rule of law applies, and it is certainly an implied term upon the letting of premises ready furnished that they are fit for residence and occupation. If it should turn out that they were not fit for the purposes for which they were let, then the tenant can rescind his agreement and even recover compensation. This rule has been laid down by several judgments, one of which was the great bug case, where a furnished house was found to be so infested with bugs as to be quite uninhabitable, and where the tenant succeeded. The same principle will apply equally to furnished lodgings; but the recent case of "Sarson v. Roberts" (*Times*, 9th July) shows that the Courts are not disposed to carry this view further than is necessary in their opinion.

This was an action brought to recover damages under the following circumstances:—The plaintiff had taken furnished lodgings of the defendant for himself, his wife, and family for three or four weeks. A few days after they went into occupation a grandchild of the defendant's living in the house was found to be ill with scarlet fever. The plaintiff was not told of this, and he stayed in the house; but, after their return home, his wife and one child were found to be ill with the same complaint. At the trial the jury found upon the evidence that the lodgings were healthy at the time of letting, but did not remain so during the term of occupancy; that the defendant did not inform the plaintiff of the scarlet fever, and that the plaintiff's wife and child contracted the fever whilst in those lodgings. Upon their findings the judge gave judgment for the plaintiff, and from this the defendant now came to the Court of Appeal. The Master of the Rolls, while admitting the rule of law that in an agreement to let a furnished house or lodging there is an implied condition that the house or lodging shall be fit for occupation at the time the tenancy begins, said it cannot be held that this rule extends to the whole term of the occupancy. In other words, there is no implied agreement that a furnished house or lodging shall remain healthy and fit for occupation during the period of the tenancy. On this ground, therefore, the appeal was allowed, and the plaintiff has no remedy for his undoubted grievance. **Fred. Wetherfield, Solicitor.**

1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

In a Fix.—Contract.—Dispute.—This is a very defective and informal contract. But I think you can claim the full 75 per cent. on the work done, as agreed; and if he prevents your completing within a reasonable time, you seem to have an action for damages, which would probably be the only way of deciding the question.

J. W. J.—Fixture.—Greenhouse.—Removal.—As this is built upon a brickwork base, I consider it is clearly a fixture, and so it cannot legally be removed by you at the end of your tenancy without rendering you liable to an action for damages by the landlord, unless, of course, he gives his consent to such removal.

New board schools are about to be erected at Llangoed, Anglesey, at an estimated cost of £2,000. Mr. Glynne Davies, of Bangor, is the architect.

The waterworks for the supply of Srinagar, the capital of Cashmere, are being vigorously pushed on by Mr. M. Nethersole, the executive engineer. Water-pipes are being laid in the streets all over the city, 5ft. deep in the ground.

The Mercers' Company, who, with the City Corporation, have the management of the Royal Exchange, have resolved to contribute a panel to the general scheme of decoration of the interior of the building. Eight or nine other panels have been promised by prominent City men, whose names have not transpired. In all cases the designs will be first submitted to Sir. F. Leighton, P.R.A., Mr. P. H. Calderon, R.A., and Mr. E. J. Poynter, R.A., and the City Corporation have voted £500 from the balances of the rents of the Royal Exchange in filling a panel with a fresco representing William the Conqueror presenting the Charter to London.

LEGAL INTELLIGENCE.

Right to Mine under Springs.—The Corporation of Bradford, finding that Mr. Pickles, the owner of a farm near that town, was tunnelling under his land in order to make available some slate formations, sought to restrain him from proceeding, on the ground that his drift would divert the water of certain springs at Wilsden, known as the Many Wells, to which the community was entitled under local Acts of 1842 and 1864. Mr. Justice North granted an injunction, which was reversed by the Court of Appeal. The Corporation carried the case to the House of Lords, which decided, on Monday, against them, declaring that Mr. Pickles had the right, as a landowner, to do what he had done, the case of "Chasemore v. Richards" being taken as a precedent. The Corporation's action was therefore dismissed, with costs.

The Powers of the Superintending Architect, L.C.C., Upheld.—Allen v. the London County Council.—In the Court of Appeal, on July 22, Lords Justices Lindley, Lopes, and Rigby delivered judgment in this case. This was an appeal by the plaintiffs against a decision of a Divisional Court (consisting of Mr. Justice Wills and Mr. Justice Wright) upon a special case. A question of general importance was raised upon the construction of section 75 of the Metropolis Management Act, 1862, 25 and 26 Vict. cap. 102 —viz., whether the decision of the superintending architect of the Metropolitan Board of Works (now of the London County Council) is binding, not only as to the general building line in a street, but also upon the question in which street or road a particular house, situate at the corner of two streets or roads, is situate for the purpose of the determination of the building line by which it is to be regulated. The special case was stated by a metropolitan magistrate, who had made an order for the demolition of a certain building in the metropolis as being beyond the building line. A complaint had been made to the magistrate by the London County Council that the plaintiffs began to erect a building beyond the general line of buildings on the north-western side of Birchington-road, Kilburn, without the consent of the County Council, contrary to section 75 of the Metropolis Management Act, 25 and 26 Vic. c. 102 The facts were these: The plaintiffs, on November 13, 1894, began to build four shops and houses upon the land at the corner of Birchington-road, Kilburn High-road, having a frontage of 22ft. to Kilburn High-road and 58ft. to Birchington-road. This front in Birchington-road extended 16ft. beyond the general line of buildings, as determined by the certificate of the superintending architect of the London County Council, who stated in it that the main fronts of the buildings in a certain row of houses formed the general line of buildings on the north-western side of Birchington-road, "in which road the building in question is situate, and the building in question would project beyond the prolongation of the said general line." It was contended on behalf of the plaintiffs that the architect had not by his certificate found that the building was situate in the "street, place, or row of houses" described as the north-western side of Birchington-road, and if he had so found, he had placed the building in a "street, place, or row of houses" in which the same was not situate. The County Council contended before the magistrate that the certificate had determined that the building was situate in Birchington-road, and that that determination was binding on the magistrate. The magistrate adopted this view, on the authority of "London County Council *v.* Cross," and directed the demolition of so much of the building as was beyond the line. The questions for the Court were (1) whether the certificate showed that the house in question was situate in the street, place, or row of houses on and for which the general line of buildings was determined? (2) Whether it was the duty of the architect to decide and find the situation of the plaintiffs' building, and, if so, whether his decision was binding on the magistrate? The Divisional Court answered both questions in the affirmative. The plaintiffs appealed. The Court delivered judgment on Monday, dismissing the appeal. Lord Justice Lindley was of opinion upon the construction of the certificate that it did decide that the plaintiffs' house was situate in Birchington-road. The question was whether, under section 75, this point was to be decided by the superintending architect or by the magistrate. His Lordship continued:—The following circumstances must co-exist in order to justify an order for demolition under section 75, viz.:—(1) There must be a building, structure, or erection of some sort. (2) That building, structure, or erection must be erected with the written consent of the Metropolitan Board of Works (or now of the County Council). (3) That building, structure, or erection must be in some street, place, or row of houses. (4) That street, place, or row of houses must have a general line of building. (5) This line of building —*i.e.*, the line of building of the street, place, or row of houses in which the building complained of is situate must be decided by the superintending architect appointed by the Metropolitan Board of Works (or now by the County Council). (6) Lastly, the building, structure, or erection must be erected beyond the line so decided. What is left to the decision of the architect is the existence and exact position of the general line of building of the street, place, or row of houses (if any) in which the building, &c., complained of has been erected. In case of dispute the magistrate must decide all the other matters referred to — *e.g.*, whether the building, &c., complained of is one to which section 75 applies, especially having regard to section 74; whether the necessary consent has been given; whether the building, &c., is in a street, place, or row of houses, "street" being interpreted as directed in section 112; whether the building, &c., has been erected beyond the general line of building for that street, &c., as decided by the superintending architect. Such is, in my opinion, the true construction of the section, and of the decision in "Spackman v. Plumstead Board of Works" (10 A. C. 229), which set at rest the doubt whether the magistrate could review the architect's decision as to the general line of building. So far the interpretation of the statute is reasonably plain. But then it is said that the question still remains, Who is to determine whether the building complained of is in the particular street, place, or row of houses to which the architect's certificate is applicable? This is the point on which Lords Watson and Bramwell differed in "Barlow v. Vestry of St. Mary Abbotts" (11 A. C. 257). A careful perusal of Lord Herschell's judgment has led me to the conclusion that he agreed with Lord Watson, and that Lord Fitzgerald took the same view. There is much to be said for this interpretation of the Act; for, the object of the Act being to regulate lines of building, the architect, rather than the magistrate, seems naturally to be the person to say to what line of building a particular house should conform. The general line of building which the architect is to decide is "such general line," and by "such" is meant the general line for the street, &c., in which the house in question is. The architect might no doubt assume, without deciding, that the building complained of was in a particular street, place, or row of houses, and simply certify the general line of buildings of that street, &c., leaving the magistrate to determine whether, after all, the building was in the street, &c., to which the certificate applied. But this would be to deprive the architect's certificate of half its value, and the interpretation which leaves him to decide what building line is to be conformed to seems to be preferable to an interpretation which leaves that question to the magistrate. For these reasons, and thinking, as I do, that this view of the section is more in conformity with the decision of the House of Lords in "Barlow's Case" than the interpretation contended for by the appellants, I have come to the conclusion that this appeal ought to be dismissed. The architect's certificate here, taken with the plan, supplies the omission which led to the decision in "Barlow's Case," and does certify, with sufficient clearness, that the appellants' house is not only in Birchington-road, but is in the row of houses the building line of which is defined. Lord Justice Lopes and Lord Justice Rigby delivered judgment to the same effect.

No Compensation for Setting Back.—The Mayfair Property Company v. the London County Council.—In this case the plaintiff company claimed to recover compensation from the County Council for having compelled them to set back certain house property in St. John's Wood under the Metropolitan Improvement Act. The case was tried before Mr. Justice Wills without a jury, and he found that the plaintiffs were not entitled to compensation. The plaintiffs appealed, and judgment was given by Lord Esher and Lords Justices Kay and Smith in the Court of Appeal on July 24th. The Master of the Rolls, in giving judgment, said the whole question was whether the County Council had required the company to set back their house property under the 74th section of the Metropolitan Act. The County Council had not done so. The plaintiff company asked the County Council would they require the property to be set back under section 74, and the Council replied emphatically that they made no such request; instead of which they proceeded under section 75 of the Act. They said that they intended to put section 75 in force, and, having done so, the plaintiff company had no claim for compensation for setting back. That was the view of the case taken by the learned Judge who heard the evidence; it was the right view, and the appeal must be dismissed, with costs. The other Judges concurred.

Plasterers' Trade Union Libel Action.—In the Queen's Bench Division of the High Court of Justice in London, on July 25th, Baron Pollock, sitting with a special jury, heard the case of "Wright and Co. v. Hennessey." This was an action for libel, and also for an injunction to restrain the defendant from continuing to publish the matter complained of or similar libels. The defendant, amongst other pleas, said he wrote the words complained of in the performance of his duty, and they were privileged. The plaintiffs, Messrs. Samuel Wright and Co., were fibrous plaster manufacturers, carrying on business at Hackney, and defendant, Daniel Hennessey, was the organising secretary of the National Association of Operative Plasterers. It was said on behalf of the plaintiffs that they brought the action in self-defence, as unless the defendant desisted from his course of action it would be impossible for the plaintiffs to carry on their business. Plaintiffs made casts of fibrous plaster in various ornamental designs at their works, and then employed unskilled workers to place them in position. They were also instrumental in forming a combination of master plasterers in London, and in 1893, when Messrs. Peak, master plasterers, had some difficulty with their men, the plaintiffs finished their contract for them. According to the plaintiffs' case, the result was that their names were inserted in a "black list" by the defendant's society, and the defendant wrote to various firms who employed them the letters which constituted the libels complained of, the contention of the society being that members of the union should be employed to place the casts in position instead of unskilled workmen. Amongst other firms the defendant, it was said, wrote to Messrs. Patman and Fotheringham, who had employed the defendants, stating that he was instructed by the London district of the society to inform them that S. Wright had been declared by the committee to be an unfair employer. Messrs. Patman and Fotheringham refused to give way and to dismiss the plaintiffs; but endeavoured to bring about a reconciliation. Subsequently, when plaintiffs were engaged on some works at South Kensington, and on some School Board work at Gravel-lane, similar letters were written, in which it was said that if the plaintiffs were allowed to do certain work, nothing but scamped work and inferior workmanship would be the result. Plaintiffs alleged that by these means firms had been induced to break contracts with them, and instanced the case of Messrs. Colls, who had a contract with regard to the Pavilion Theatre at Whitechapel, who employed the plaintiffs. That firm received a letter from the defendant, stating that plaintiffs' action had caused a revulsion of feeling in London. The result of the letter, it was said, was a strike, and plaintiffs had to be sacrificed in order that the work might go on. The defence substantially was that there was no malice against the plaintiffs in the course adopted, and that what was done was done in the interests of the trade union. The statements made to different masters were only to the effect that if the plaintiffs' men were kept working at particular buildings all union men would withdraw. Further, it was contended that what was thus done in the interest of the union was not illegal. The jury found that the conduct of the defendant was improper, and awarded the plaintiffs £300 for the loss of trade and £500 for the libels. His Lordship entered judgment for the plaintiffs, and granted the injunction asked for. Notice of appeal was given.

CHIPS.

Forty-eight members of the Royal Scotch Arboricultural Society have arrived at Bremen, whence they will start on a tour to study the principal forestry establishments of Northern Germany.

The death is announced of Mr. Harold William Abernethy, M.Inst.C.E. He was superintending engineer of the Runcorn division of the Ship Canal during its construction. After the completion of the work he, in accordance with medical orders, proceeded to the Cape. He died on the return voyage, and was buried at sea. He was in his 37th year, and was the son of Mr. James Abernethy, M.Inst.C.E., Broadstairs and London.

The Memorial Church to Lord Nelson at Burnham Thorpe, his native village, was opened by the Bishop of Norwich yesterday (Thursday). The cost of the rebuilding of the parish church has been £5,000.

The contractor, Mr. Relf, has finished his part of the work in doubling the Cornwall line of the Great Western Railway between St. Germans and the Menheniot viaducts, and the new line now only awaits the rails and sleepers of the company to be brought into use.

The rural district council of Doddington, Cambs, have adopted plans for sewering the parish of Doddington, prepared by Mr. John Cooke, of Stewton, Louth. The estimated cost of the scheme is £1,100.

Charles Dickens's desk has been given by Mr. Bancroft to the South Kensington Museum, where it is placed in the Forster Library. The desk bears the following inscription:—"This desk belonged for many years to Charles Dickens, and was last used by him a few hours before he died, on June 9, 1870. His executrix afterwards gave it to Edmund Yates: at whose death it was sold by public auction on January 21, 1895, and bought by S. B. Bancroft: who presented it to the South Kensington Museum."

WATER SUPPLY AND SANITARY MATTERS.

Aldershot Camp Sewage Farm.—Mr. E. Bailey Denton, M.Inst.C.E., has severely reported on the condition of the camp sewage farm at Aldershot, declaring that the systematic neglect of years is apparent at every turn. The homestead is next door to a ruin; and there is not a gate on the whole farm. The condition of the roads and fences likewise is very bad. The tanks at the outlets of the four outfall sewers, which were never of good design, and are most unsuitable for the deposition of sludge, have fallen into decay, and present a disgraceful appearance, the large quantities of sludge collected in them giving off nauseating odours. Much of the land is out of cultivation, and the sewage collects in the low places, forming stagnant and offensive pools. The main furrows by which the sewage ought to be rapidly conveyed from the various tanks for distribution over the land have, from want of attention, become simply large and ill-shoped ditches, which serve to collect the sewage and check its rapid conveyance to the various points of out. The smaller branch furrows have been equally neglected. Mr. Denton adds that the present disgraceful state of things is entirely traceable to long and continued neglect. With proper management there would not, however, be a better or more successful sewage farm in England. —At the meeting of the Surrey County Council, on Monday, the sanitary committee reported that they had received a communication from the Thames conservators, stating that they had written to the War Office respecting the serious character of the pollution from the sewage farm at North Camp, Aldershot, and that they were now serving a notice upon the department requiring discontinuance of the nuisance. The county medical officer reported that at a recent visit to the camp he learned that the land adjoining the river Blackwater was no longer used for the treatment of sewage, and consequently the further pollution of the river was not to be immediately feared. Mr. Welch (chairman of the committee) said the matter appeared about to be closed so far as that council was concerned. He drew the attention of the council to Mr. Bailey Denton's report, which backed up the county council in every way. The sewage was now being treated on another part of the farm, and, as a county, they had no further cause of complaint at present. It was, however, a national matter, concerning the health of the troops, and he thought the council had done well in drawing the attention of the War Office to it.

The Dearth of Water at the East End.—At Tuesday's meeting of the London County Council, reports were read from the Parliamentary agent and the engineer to the Council in reference to the statements of the East London Water Company that their lack to furnish a sufficient supply was really due to the action of the Council in opposing their Bill of 1893. Mr. Cripps, the Parliamentary agent, said the allegation was absurd. The Council did not oppose the construction of additional works by the company, but only certain proposals for the creation of a large amount of additional capital in debenture stock and for the imposition of onerous and arbitrary conditions on consumers. The report by Mr. Alexander R. Binnie, the engineer, expressed the opinion that the cause of the scarcity of water was not shortness of supply, but the fact that the company's pipes had been so shattered during the frost of last February as to have become leaky, so that the water was wasted. It was resolved to send copies of the report to the East London Waterworks Company. At the same meeting, the Council authorised the expenditure of £2,500 between the present time and March next for making further surveys and obtaining the necessary information with regard to a supplementary source of water supply for London, with the following rider, moved by the Earl of Onslow: "It being understood that, in authorising the expenditure, the Council in no way pledges itself to proceed further in the matter or further to consider the whole subject."

The Purification of the Clyde.—The sewage committee of Glasgow Town Council have decided to proceed with the scheme for dealing with the sewage on the north bank of the Clyde with a view to the purification of the river, and to recommend the council to promote a Bill authorising the necessary capital—about £600,000. Negotiations are to be opened with the various local authorities—Clydebank, Partick, &c.—with the view of treating all the sewage which, if not intercepted, would enter the river between the city boundary and the corporation lands at Dalmuir, where the new sewage works are proposed to be erected. Consideration of a similar scheme for dealing with the sewage from the south side of the river has been deferred until powers for the north bank scheme have been obtained.

* * *

Archbishop Stonor opened, on Monday, the new chapel attached to the Convent of the Sisters of Mercy in Blandford-square, N.W.

Our Office Table.

* * *

At a general meeting of the Royal Academy, held on Thursday night in last week, Mr. E. Onslow Ford, sculptor, and Mr. W. B. Richmond, painter, were elected Royal Academicians. Mr. E. Onslow Ford, who has been an Associate of the Academy since 1888, was born in London on July 27, 1852. In 1870 he went to Antwerp, where he studied painting under M. Buffeau, proceeding in the following year to Munich, where he joined the Academy. Having given up painting in favour of sculpture, he returned to England in 1874. From 1882 until the present time he has been a prominent exhibitor of statues and busts at the Royal Academy. Mr. W. B. Richmond, who shares with Mr. Onslow Ford the distinction of promotion to the full rank of Academician, was born in London on Nov. 29, 1843, the son of Mr. George Richmond, R.A. Entering the Royal Academy as a student, he obtained two silver medals in 1857. In 1859 and 1860 he travelled in Italy for artistic purposes, and in 1865 paid a second visit to that country for the purpose of studying in Rome, where he worked at sculpture, architecture, fresco, and tempera painting. In 1870 he returned to England, and soon became a prominent exhibitor of subject paintings and portraits both at the Academy and elsewhere. In 1878 Mr. Richmond succeeded Mr. Ruskin as Slade Professor at Oxford, but gave place to Mr. Ruskin in 1883. He became an Associate of the Royal Academy in 1888, and has of late given his exclusive attention to the mosaic decoration of St. Paul's Cathedral. Portraits and biographies of both the new Academicians appeared in the Building News for May 9, 1890.

In view of the difficulties and misunderstandings which continue to arise in the matter of architectural competitions, the Council of the Royal Institute of British Architects have appointed a special committee, consisting of the Past-Presidents, Messrs. Charles Barry, F.S.A., Alfred Waterhouse, R.A., and J. MacVicar Anderson; of the Past Vice-Presidents, Mr. Henry Currey and Sir Arthur Blomfield, A.R.A.; of the Presidents for the time being of the Architectural Association (London), the Birmingham Association, the Liverpool Society, and the Manchester Society; with Messrs. James Brooks, Cole A. Adams, Edward W. Mountford, and Rowland Plumbe, Fellows; and Mr. G. Richards Julian, Associate. All these have consented to act, and the committee will be called together at an early opportunity.

The Council of the Royal Institute of British Architects also announce that the Practice Standing Committee of the Institute propose to undertake the reconsideration of the schedule of professional practice and charges of architects, with a view to its revision if thought advisable; and that the committee are prepared to receive from members of the Institute generally any suggestions for alterations or modifications of the several clauses, to which they will give careful attention. Such suggestions should be addressed to the Hon. Secretaries of the Practice Standing Committee at the Office of the Institute.

The Duke of Devonshire will open on Wednesday in next week the new home at the Colony for Epileptics, Chalfont St. Peter, Bucks, which has been established, at the cost of Mr. J. Passmore Edwards, in connection with the National Society for the Employment of Epileptics. The colony at Chalfont St. Peter consists of 135 acres of land, and, when fully developed, it will form an industrial village where, under proper care and supervision, epileptics of all ages and both sexes, living in separate homes, will follow the avocations of ordinary life; children will be educated and suitably trained, and adults will be occupied in useful work of various kinds. The colony was inaugurated last August, and already the progress made by the colonists in health and happiness is pronounced by the honorary medical staff to surpass the anticipations of the most sanguine. There is at present accommodation only for men; but the success of the experiment has led to offers of funds for the erection of three new homes—one for women and one for children of each sex. But these developments will necessarily involve much expenditure beyond the cost of building, for there will be, for instance, the cost of furnishing, and it will be necessary to erect workrooms and a laundry for the women, and school accommodation for the children. An appeal is, therefore, being made for additional funds for the National Society for the Employment of Epileptics, so that the work may not only be carried on, but extended.

At Wednesday's sitting of the Congress of the Institution of Mechanical Engineers, now being held in Glasgow, Mr. James Deas, engineer of the Clyde Navigation Trust, read a paper on "Recent Engineering Improvements of the Clyde Navigation." The paper dealt with a period of seven years from July 1, 1887. During that period no fewer than 11,401,978 cubic yards of material had been dredged from the river at the cost of £303,881 1s. 3d. The material so dredged had been deposited on land in Loch Long, off Garelochhead, and in other parts of the river and Firth. The quayage of the harbour, including Kingston Dock, Queen's Dock, and Cessnock Dock, so far as in use, was now seven miles in length, all of which was tidal, with a water area of 185 acres. It was also stated that the water area of the Cessnock Dock, when completed, would be 34⅔ acres, the area of quayage 36⅔ acres, and the length of the quays 3,760 yards. In replying to a vote of thanks, Mr. Deas said he did not think the maintenance of the quay walls had cost the Clyde trustees £100. Not even a brick had been required to be replaced since erection.

During the congress of the British Medical Association, which is being held in London this week, the president and council of the Sanitary Institute have thrown open their museum and rooms in Margaret-street, W., to members of the profession, and have convened a series of three afternoon meetings for short discussions on hygienic questions. The first of these was held on Tuesday evening, when the selected topic was "The position of medical officers of health in regard to the administration and working of the Infectious Disease Notification Act." Sir Thomas Crawford presided, and in introducing the subject remarked that the position of medical officers of health who were general practitioners was not satisfactory, because they were not sufficiently independent. He thought, therefore, that medical officers of health should have a district large enough for their remuneration to enable them to do without practice. A large proportion of cases could be dealt with in any ordinarily well-regulated house, with proper precautions, without removal to a hospital; and, instead of the list of diseases in the Act being extended, he thought it might be reduced. Dr. Alfred Hill, of Birmingham, agreed with the chairman that a medical officer of health should not be a general practitioner. Sir Douglas Galton said the number of persons who desired to use the hospitals of the Metropolitan Asylums Board increased so largely that the managers were continually obliged to build new ones. Dr. Sykes, of St. Pancras, said the difficulty in London was not to get people to go to the hospitals, but to keep them out. On Wednesday evening, Professor Wynter Blyth gave a peripatetic lecturette descriptive of the chief exhibits of the Parkes Museum; and last (Thursday) evening a discussion took place on stream pollution, opened by Dr. Percy Frankland.

The City Commission of Sewers are now in possession of a well-equipped laboratory for the carrying out of the provisions of the Electric Lighting Acts, the rules and requirements of the Board of Trade in regard to meter-testing, and the supervision of lines and mains vested in the local authority. The Commission of Sewers are large consumers of electrical energy as the lighting authority of the City, and meter-testing will be the principal work of the laboratory, which is situated in Basinghall-street, and for this purpose complete arrangements have been made. The electrical current is taken from the street mains of the City of London Company, and as under the present system the current is taken off at a pressure of between 100 and 200 volts, which is much greater that required for the purpose, a special transformer has been provided.

The Governors of the Borough-road Polytechnic have agreed to undertake the responsibility of conducting the Norwood Institute, Knight's Hill-road, S.E., on lines somewhat similar to the parent institution. For this purpose the Technical Education Board of the L.C.C. have consented to provide the sum necessary for immediate outlay, and to make a special yearly grant to the funds of the Polytechnic. Mr. Leslie Waterhouse, M.A., A.R.I.B.A., has been intrusted by the local board of governors with the task of adapting the premises to their requirements. It is hoped that the building may be opened in September.

The Birmingham Municipal School of Art, as last year, comes easily to the head of the art schools of the United Kingdom in the awards gained at the National Competition held by the Science and Art Department. The Birmingham school has gained a gold medal (one of the five awarded, and won by Winifred Smith with designs for book illustrations), eight silver medals, twenty-two bronze medals, and a large number of book prizes, the successes being more numerous than in 1894. This should be gratifying to Mr. Edward R. Taylor, the head-master. The Glasgow School of Art has also done well, having gained forty-three awards against thirty-nine last year. These include the highest for architecture in the kingdom, the chief being the gold medal won by Albert H. Hodge for an architectural design, and four silver medals—gained by Andrew Allan, John Moffat, George A. Paterson, and George Smith—are for modelling design, modelling antique, architectural design, and studies from the life.

The Tramways Company of Bristol have just carried out by workmen in their own direct employ the reconstruction of the old line between West-street and St. George's, so as to fit it for use by electric cars. The work, which included the removal of the old rails and chairs and the substitution of heavier metals over a length of three miles of single line, has only occupied six weeks, and has been carried out under the supervision of Mr. C. Challenger, on a report by Mr. J. Clifton Robinson, C.E. The directors have voted £100 for distribution among the foremen of the gangs and others engaged on the work as an acknowledgment of the way in which they had stuck to their posts night and day. A further extension from the old terminus at St. George's to Kingswood and a section of reconstruction in Old Market-street are being carried out by a contractor, and have also a linear run of about three miles. The tramways company had already contracted for the extension and for the doubling on the Horfield and Stapleton-road lines, and for the Bedminster extension, or they would have kept together their construction staff.

Mr. Andrew George Ashcroft, who has just been appointed principal of the Woolwich Polytechnic, has been for many years first assistant to the Professor of Engineering at University College. When Prof. A. B. W. Kennedy left the college, Mr. Ashcroft accompanied him, and was responsible for the equipment of Prof. Kennedy's laboratory at Westminster. He also assisted Prof. Kennedy in the design of the iron and steel work for several important buildings, and made all the arrangements for Prof. Kennedy's trials of marine engines conducted under the auspices of the Research Committee of the Institution of Mechanical Engineers. After working with Prof. Kennedy privately for about a year, Mr. Ashcroft returned to University College as assistant to Prof. Hudson Beare, and in that capacity took a leading part in the design and equipment of the new engineering laboratory. He is also the inventor of some ingenious appliances for measuring small strains.

The Improvement Committee of the Birmingham City Council have reported to that body that the Act of Parliament confirming the Provisional Order of the Local Government Board, with reference to the Milk-street improvement scheme, has received the Royal assent. The property scheduled for the scheme comprises an area of 4,030 square yards, and there are 66 dwellings and a few workshops standing thereon. The gross rental of the whole is £145 per annum, and the sum of £6,000 will be required for the purchase of the site and all interests. The claims have all been satisfactorily settled except three, which will go to arbitration. The Local Government Board have inserted clauses in the scheme providing for the utilisation of the land for working-class houses, and forbidding its appropriation to other purposes without permission of the Board. The Improvement Committee recommend that, upon obtaining possession of the land, they be authorised to clear the site, and afterwards endeavour to dispose of the same for the erection of suitable dwellings for the working classes. In the event of their being unable to so dispose of the land, the committee propose to report again to the council, with their recommendations for the erection of houses by the council, submitting the necessary plans and estimates. The report was adopted by the Council on Tuesday.

The annual report to the Toxteth Park urban district council by their surveyor, Mr. John Price, M.S.A., shows that the district is making steady progress, the year's expenditure on highway repairs having been £2,543, against £1,870 and £1,845 in 1893 and 1892 respectively. A large item was the reconstruction of Smithdown-road, leading to Sefton-park Station, carried out under contract by Mr. W. F. Chadwick for £1,081. The outlay on street works has exceeded the average, having been £1,760. The sewer in Greenbank-road has been reconstructed by Mr. W. Musker, at a cost of £2,068, and will shortly be extended at an estimated further cost of £1,800. A refuse destructor has been built. The contract for the erection of the buildings has been carried out by Mr. John Webster, of Wavertree, for £1,100; that for the erection of the chimney, 186ft. high, by Messrs. Holden and Myles, of Stalybridge; and that for the construction of six destructor cells on the Boulnois and Brodie patent system, with Henderson's mechanical firebar and Jones's cremator, was let to Messrs. Manlove, Alliott, and Co. for £4,150. The works are in a forward condition. The contract for the engine for lighting the works by electricity was let to Messrs. Ransome, Sims, and Jefferies, of Ipswich, and for the dynamo to the Electric Construction Company, of Wolverhampton. The installation will shortly be completed. A town's depot and stabling are being constructed at Richmond Lodge. The contract for the erection of the various buildings was let to Mr. Thomas Spencer, of Bull Bridge, Aintree, for £2,200, and the works are now very nearly completed. A fire-brigade station has been built for the council in Lark-lane by Mr. T. F. Hill, of Woolton, who has also carried out the contract for enlarging the public offices. The number of new buildings approved, 199, shows a decrease on former returns, but the number of occupied houses, 4,577, is more than at any previous period, and over 100 other houses are in course of erection.

The completion of the Boulevard Haussmann has, says the correspondent of the *Standard*, once more become one of the great questions of the day for Parisians. All that remains to be constructed is a length of 270 mètres, but the ground between the Rue Taitbout and the corner of Rue Drouot, where the Boulevard Haussman will, when prolonged, join in a straight line the Boulevard Montmartre, is, perhaps, the most valuable of all Paris. The approach of the Universal Exhibition of 1900 is, however, not only stimulating private enterprise, but also the Municipal Council, which has now adopted the favourable report presented to it by M. Thuillier, in the name of the Commission to which the Boulevard Haussmann question had been referred. M. Thuillier recognises that the improvement will be a costly operation, but he, nevertheless, advises that it should be carried out without delay, lest at a later date it should prove yet more costly. In 1886, two contractors, MM. Lardonnois and Papon, offered to complete the boulevard for fifty-three million seven hundred and seventy-two thousand one hundred francs (about £214,000 sterling), and to hand over to the Paris Town Council the ground necessary for the construction of the roadway with its sewers. That price was considered too high, and the offer was rejected. Two new proposals have recently been received for the completion of the boulevard. The Société Immobilière du Boulevard Haussmann asks an annuity of five hundred and forty-nine thousand six hundred and forty francs (nearly £2,000 sterling) for sixty years, for which it would guarantee the completion of the boulevard within a comparatively short time. It is believed that the Boulevard Haussmann will be completed before the opening of the Exhibition in 1900.

A report has been submitted by Lewis M. Haupt on the route of the proposed ship canal from Philadelphia to the Atlantic Ocean, across the State of New Jersey, in which he gives interesting information with regard to the sizes of locks required in the States for different classes of traffic. For canal boats and barges the length desired is 205ft., width 24ft., and draught 10ft.; for coastwise vessels 340ft. by 44ft., with draught of 20ft.; and for battleships and cruisers 500 by 65ft., with 28ft. draught. Six locks would be required for the whole route, of which only 31 miles would be cut through the solid land, the remaining portions including part of the Delaware River and Raritan Bay. He estimates the cost of a canal 20ft. deep at £3,000,000 sterling, and of a 28ft. canal at £4,800,000.

CHIPS.

Messrs. Ogilvie, Gillanders, and Co., of London, have taken the contract for constructing the Delhi-Bhatinda-Samasata Railway. The capital required will be at least 1½ million sterling, and the line is estimated to cost 259 lakhs.

The Local Government Board have authorised the purchase of the Tooting College estate by the Wandsworth and Clapham Board of Guardians for the sum of £40,000 as a home for the aged and infirm poor.

The board of guardians of Burton-on-Trent have under consideration a report by Mr. Stevenson, architect, on proposed alterations to the house, including separate wards, accommodation for nurses, children's wards at the hospital, and enlargement of the laundry and washhouse. The estimated outlay is put down at £4,820.

The Margate Town Council have decided to offer £2,500 to Messrs. Lewis for a slip of land 100ft. deep, forming part of the Cliftonville estate, so as to widen the popular promenade to the east of the town, leading from the fort to Hodge's flagftaff.

The Lady Chapel at the Church of St. Matthias, Earl's-court, which has been restored and decorated at a cost of £500 in memory of Miss Davidson, daughter of the vicar, was reopened on Saturday.

During the works going on in the central quarter at Florence considerable Roman remains have been found of very large buildings, and also of an urban Roman road in the Via della Nave, and of a burial place near the Palazzo Medici.

The purchase of Carlyle's house in Cheyne-row, Chelsea, has been completed at a cost of £1,730, and a great many articles of furniture, books, and other personal memorials of Mr. and Mrs. Carlyle have been collected there. The house is open to public inspection, a fee of a shilling being charged for admission, to provide for maintenance.

In connection with the completion of the Baptist chapel in Brynland Avenue, Horfield, near Bristol, the workmen, to the number of 80, in the employ of the contractors, Messrs. R. Wilkins and Sons, were entertained at tea by the members of the building committee on Thursday in last week. Mr. Herbert Jones, of Bristol, is the architect.

On Saturday afternoon the memorial stone was laid of the public library which is being built at Thornliebank, N.B., to commemorate the late Mr. Alexander Crum, of Thornliebank, and for some time M.P. for Renfrewshire. The building is in the Classic style of architecture characteristic to Scottish buildings in the 17th century, and the architect is Dr. Rowand Anderson, Edinburgh. The cost will be about £2,000.

At the Blackburn County Court, on Monday, the Accrington and Church Outfall Sewerage Board were sued by the Ribble Committee for disobeying an order to carry out a sewerage scheme within 18 months. Judge Coventry said there had been unjustifiable delay by the defendants in spending seven months in experiments instead of adopting a scheme. He imposed a penalty of £250, which is at the rate of £10 daily, with costs on the higher scale.

A meeting of the Governors of the Birmingham and Midland Counties Sanatorium was held at Birmingham, on Monday, under the presidency of the Mayor, to consider the offer of Colonel J. H. Wilkinson to present the Royal Hotel, Sutton Coldfield, as a sanatorium. The hotel, which is valued at £20,000, occupies a commanding position overlooking Sutton Park. It stands in its own grounds of five acres, laid out in picturesque style. A resolution was adopted gratefully accepting Colonel Wilkinson's generous offer.

Probate of the will, dated January 11th, 1894, with a codicil made the 3rd May, 1895, of Mr. James Piers St. Aubyn, architect, of Chy-an-Eglos, Marazion, who died on the 7th May last, aged 80 years, leaving personalty valued at £43,776, has been granted. The testator bequeaths to his clerks Henry Wadling, Henry Luff, and John Davis £200 each, and to his clerk Horace Bradfield £100. Mr. St. Aubyn also bequeaths £1,000 in trust for the augmentation of the living of Marazion.

The corner-stone of a girls' department in connection with the parish church schools, Church Hill, Wednesbury, was laid by the mayor on Monday. The new building will adjoin the old schools, and with certain alterations of the existing buildings will afford additional accommodation for 300 children, whilst improved outbuildings will be provided. The work is being carried out by Messrs. Morriss and Atkinson, Lansdown-street, Birmingham, from designs by Mr. J. H. Gibberns, City-road, Birmingham.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2118.

FRIDAY, AUGUST 9, 1895.

ANOTHER COMPETITIONS COMMITTEE.

"IN view of the difficulties and misunderstandings which continue to arise in the matter of architectural competitions, the Council [of the Institute] have appointed a Special Committee." As far as we have observed, the chief problem, for the last five or six years, has been the difficulty in each case of getting—we will not say the best—but even a decently creditable design selected by the assessor. The failures which have followed each other in rapid succession were hardly to be matched in the bygone times when there was no assessor at all. Disgraceful as to architecture, and in flat opposition to the "Instructions," very often as to size and accommodation, many of the schemes which have been picked out for adoption ought to have ended at once the career as adjudicator of the man who recommended them. In the opinion of the Council of the Institute, they do not seem to have affected it—a fact which does not inspire us with much confidence in the Council's committee.

For all the good it does at present, the assessorship system has practically broken down; and, as everybody knows, it has broken down for this reason: that assessors have got appointed, not for their competence, but for their position. They have been appointed simply as presidents, or past-presidents, or vice-presidents, or professors. The outside world inquires no further. A man who presides over other architects must, it takes for granted, know more than they do, and, knowing more, he must be a better judge. Once in the history of the Institute such a thing *has* actually happened. There has been one President—and though some others have been eminent, only one—who might claim to have made all architectural knowledge his province. Among Mr. Waterhouse's many accomplishments, perhaps the rarest has been that of grasping the essential needs of the most varied sorts of building. His selections were as wise as they were artistic, and he has earned the respect of the profession almost as much for what he has enabled other architects to do as for what he has done himself. But since he has practically ceased to act, the weak point in the assessorship system has become more and more glaringly conspicuous. "The architectural assessor is to select a design for execution." All very fine; but who is to select the assessor?

Office and ability, as we have just seen, do sometimes go together; but it is the exception, rather than the rule, and it is of the last importance not to encourage the public in their delusion that a holder of the one is sure to be gifted with the other. The new Competitions Committee includes able men, Mr. Waterhouse amongst the rest; but of its 14 members, nine are past-presidents or vice-presidents of the Institute or presidents of cognate societies. Obviously enough, it has been made up on the principle—the false and mischievous principle—that to be placed at the head of some architectural body qualifies a man, or proves him to be qualified, for deciding on the issue of an important competition. It teaches him all mysteries; it gives him taste and skill and insight, when by nature he had none; it makes him an authority on planning of everything, from cathedrals to baths and wash-houses, and it ought to induce his fellow architects to accept, with unquestioning faith, whatever awards he may think well to make amongst them. Of course, we all know that it does nothing of the sort. What it really does is once in a while to make some weak man fancy that it has effected this for him, so that he is quite prepared to sit in judgment on other people's churches, town-halls, board schools, or anything else – though he never built a church, a town-hall, or a board school that anybody would care to look at twice.

We must hope for the best. We can only trust that the ability on the Committee may overpower the officialism, and that the majority of its members will take the opportunity of passing a self-denying ordinance, and will bind themselves not to adjudicate on what they do not understand. But to do much good, they must go far beyond this. Let us imagine ourselves for a moment stripped of all professional knowledge, and turned into members of some council or committee with a new building to arrange for. Half of us do not know what an architect is. Some of us think he is a combination of builder and estate agent. Others take him to be an engineer who has come down in the world, and who devotes himself to small matters because there are no more railways to be made. Fortunately, the chairman is having a house built, and he volunteers to ask his contractor. That gentleman, remembering the arbitration clause in some bygone agreement, is able to state with certainty that there is an Institute of Architects, and that this institute has a president. When designs are advertised for, and the board or committee learn for the first time that competing architects want a professional assessor, what is more natural than to ask the president to be that assessor? If the president declines, perhaps he may still furnish them with the names of previous presidents or vice-presidents, and then they may hand over the settlement of what their future building is to be like, to the best or the worst of these, just as it happens.

We architects have a pretty clear idea of who is fit and who is not fit to adjudicate on each particular class of building. We know what two or three hundred, at least, of our more prominent fellow-workers have done; and, consciously or unconsciously, we have formed an estimate of what is to be expected from each of them. But the general public can make no such estimation. It hardly ever occurs to them, for instance, that one man is good at churches, another at houses, and a third at public halls. They suppose that any architect can design anything, and that one architect is likely to do it about as well as another. It seems of little consequence to them, therefore, who is appointed to decide, or they want to appoint some local man—some "respected fellow-townsman"!! If they cannot agree on him as architect, without a competition, and if he sees no chance of his own success in a competition, then, failing presidents and ex-presidents, they will put him in as assessor. This is how it comes to pass that when competitors are not sat upon by the official man, they are so often disposed of by the local man. Possibly he understands the rule of "ca' me, ca' thee"! and, for good reasons, assigns the work to another local man. But, however this may be, probabilities are strongly against his having any sufficient acquaintance with the class of work he is deciding on. The official assessor we know, and the local assessor we know, but the fair and competent assessor is in danger, before long, of becoming no more than a memory.

When a gentleman who had been unhappy in his first marriage took to himself another wife, Dr. Johnson described it as "the triumph of hope over experience." Much more might it be so described when a competitor who has observed failure after failure in getting the best design selected, sends for "instructions" and resolves to compete again. A reasonable man can acquiesce in an award which shows that he is fairly beaten. He measures himself against the successful competitor, sees in what he is inferior to him, and sets about removing the inferiority. In that case there is hope for him in work. But there is no hope, except from the chapter of accidents, when some good-for-nothing design gets the first place, as so many good-for-nothing designs have done in the last few years. What is the advantage in skill, or study, or invention, when the decision rests with a wooden adjudicator who cares for none of these things? What is the use of sending in designs under such circumstances? It would be infinitely less troublesome, both for the committee and the competitors, if the latter simply drew lots for the commission, and submitted no drawings at all. A wooden official, even in high place, may be borne with as an official. If he is capable of being nothing better, he may still serve as an ornamental figure-head, and the ship will sail on, whether he has brains or no brains. But it is a very different matter if, after he has served his time and been unscrewed, people set him up as an oracle, and ask him to decide this or that for them. The good figure-head never refuses. He nods this way or that way, as the wind happens to blow him, and his votaries act accordingly. But their actions are mere results of chance, and the chances are that they will end in calamity.

So much for the present state of things. How can it be remedied? We must get rid, once and for ever, of the idea that to have been some sort of a president or some sort of a professor qualifies a man to settle the result of a competition. Presidents and professors are not made so for their skill in selecting the best schemes out of a multitude, especially when those schemes relate to classes of work which they have no personal knowledge of. To be a president or a professor, at least in artistic matters, implies, not so much ability as respectability. Once in a while intellectual power may go along with it, but normally it is disregarded, and sometimes it is even objected to. Yet intellectual power, along with artistic judgment, is the very thing that is wanted as the basis of an assessor's character. Fairminded of course he must be, and his fairness should be guarded by shutting him out from all inducements to be unfair. The local man may, for instance, often make, in his own line, a very good assessor, but not for a building in his special locality. If an assessorship is an honour, then the architect, like the prophet, should be without honour, at least of that sort, in his own country. Elsewhere he may be called in with advantage. There the forces which tend to attract him from the straight path are too strong, and he should not be exposed to them. But intellectual power, artistic judgment, and fairness are not enough. An assessor may have all these and fail miserably. Something else is wanted, which can only be gained by long study and experience, and that something is a knowledge of the requirements and possibilities of the particular sort of building to be adjudicated on.

The sorts of building which have to be adjudicated on are almost innumerable. No one man understands more than a fraction of them, and yet no man can make a satisfactory award about what he does not understand. The promoters themselves—the boards and councils, and committees, which send out "Instructions"—do not really know what they want, except, perhaps, as to size and cost. The first thing, therefore, is to turn these "Instructions" into "Suggestions," and leave competitors free to follow them where they are wise, and to reject them where they are foolish. But this is the last thing which the wooden assessor would approve of. His idea, the one idea which makes it possible for him to act at all, is just to take the "Instructions," wise or foolish, and to kick out everybody who has not followed everything in them to the letter. Any clerk could do as much. There is no need to pay 50 or 100 guineas for it, and if the wooden assessor can do no more, that, by itself, is reason enough for mending or ending him. He selects the design which follows the instructions most closely, and if it does not please the committee when it is built, why then, he thinks, they have nobody but themselves to blame. The competent assessor looks at the matter very differently. "The committee," he says, "have called me in, not to do what any clerk could do, but to give them the wisdom and experience in these matters which they have not got, and could not reasonably be expected to have. They want me so to advise them that they may obtain the best and most suitable building which their means will allow, and their 'Instructions' must be read with the clear recollection that this is what they were aiming at from the first." The result is, that he picks out the best design, and not the most slavishly subservient one; and when it is carried into execution, it commonly proves that he has acted wisely and well.

The practical lesson from all this is that we want a published list of public assessors, classified according to the sorts of work which they specially understand, and that this list should be made as accessible as may be to the public when they think of initiating a competition. Certain architects, for example, whose works had qualified them, would appear in it—perhaps to the number of two or three dozen—as assessors on church building; certain others on municipal buildings; others on public halls and concert-rooms; others on Nonconformist chapels and schools; others on board schools, on workmen's dwellings, on laying out estates, on factories, on sanitary works, and on a great many other things which at one time or another are arranged for by means of a competition. This list might be appended to, or referred to in the Institute's suggestions about the conduct of competitions, and when once the public become aware of its existence, there is no reason to doubt that they would appreciate its value as a guide. The wooden assessor would disappear; the figure-head would cease to be an oracle; and in place we should have men who would act with judgment, taste, and skill.

THE INSTITUTE SCHEDULE OF CONDITIONS.

A FEW weeks ago we referred to certain clauses of the revised schedule of conditions which were discussed at the Institute of Architects bearing upon variations and extras. We have now a copy of the complete schedule and form of agreement which has been issued under their sanction, and which is, so far as it is possible to do so, intended to supersede the "Heads of Conditions of Builders' Contracts," which has been often used by the profession. As we said in our former remarks, the Council of the Institute had been unable to arrive at an agreement with the council of the Institute of Builders on several points, especially the arbitration clause, and the Builders' Institute have framed a clause of their own on this head. No doubt it would be difficult to get builders to think the same as architects on all questions of contract; if they did agree, it would probably be at the expense of the other contracting party; yet it will be confessed that in questions of arbitration there ought to be a common ground of mutual understanding. Comparing the new schedule with the old "Heads of Conditions," agreed to in 1880, we find that the clauses are not only more numerous in the new schedule, but have been considerably recast. The "Heads" did very well for architects as hints, and as an aid to the memory to prevent any omission; but they were not well put together, and under the same head two different requirements were found—in fact there was an apparent want of sequence and connection. In the present schedule the various items are more consecutive, and the wording more explicit.

We will now examine a few of the more important clauses. The old "Heads of Conditions" contained 21 headings, while the new schedule has 32 clauses. Why so many clauses, so large an increase in the number of sections? may be asked. For many reasons it would have been better to curtail than to increase the number of conditions; yet in a model set of conditions it is no doubt wise to err on the side of amplification, so that an architect may select those clauses he thinks desirable for his particular case. A few new clauses have been added, as No. 18, on "works to be opened up at request of architect"; clause 20, on "sub-contractors," both important additions; others have been made by splitting up the old heads into two or more parts. The arrangement has therefore been completely altered. Thus the old clause No. 1, requiring the contractor to provide everything necessary for the due and proper execution of the several works, is embodied in the new schedule under clause 4. These clauses are practically the same, though the revised form is in more concise terms. Clause 2 in the old "Heads" refers to the contractor conforming to the regulations of the authorities and to giving notices. The new form, clause 5, is certainly more explicit, and the contractor is required, before "making any variation from the drawings or specifications that may be necessitated by so conforming, to give the architect written notice, specifying the variation, and applying for instructions thereon"—a very important condition, as it will prevent the contractor doing any work or making any variation unknown to the architect. Under the old clause the builder might conform to the provision of any by-law without consulting the architect, whose drawings and specification might be completely ignored without his knowledge, and an extra or variation be entailed without sanction. The old "head" 3 as to contractor setting out work is now embodied in two clauses, 6 and 7, the first making the contractor responsible for his own setting out, and the latter binding him to conform to the specification as to materials and workmanship, and to produce vouchers if architect so desires.

An important modification is made in respect of the clause requiring architect to furnish copies of drawings and specification (4 in old form). The old clause was that "complete copies of these documents signed by the architect are to be furnished by him or by measuring surveyor to the contractors for their own use." The new schedule, clause 2, says: "One complete copy of all drawings and of the specification shall be furnished by the architect free of cost to the contractor for his own use," and he is also to furnish to the contractor within so many days after request any details which the architect may think necessary, and such copies and details are to be kept on the works till their completion, and are to be returned to the architect on the completion of contract. The insertion of details in this clause is important. Many contractors are not anxious to have detail drawings; others ask in vain for them till the work is done without them, and the building suffers. Appended to the old clause (4) is the sentence: "The contractors are not to sublet the works without consent in writing of the architect," a curious instance of the mixing-up of different conditions. This is now inserted in clause 19. A similar division is made of the old clause 5. The first part said the architect is to have at all times access to the works, which in the new schedule comes in clause 10, and gives him or his representative also access to the workshops of the contractor; and the latter part stated, the architect may require the contractor to dismiss any person in his employ who may be incompetent or misconduct himself—a condition now found in clause 9.

We now come to one of the most important clauses in the new schedule under the heading of "Variations and Extras," about which we have said something. It will be remembered the old clause (6) only stated that the contractor was not to vary or deviate from drawings or specification, or execute any extra work, unless the same was to comply with any Act of Parliament or by-law, or unless on the authority of the architect, to be shown by an order in writing, or any plan signed or initialled by him as an extra or variation, or by any subsequent signed approval; but it did not give the contractor any opportunity of questioning whether the detail or drawing is fairly within the contract or not, which was left to the *fiat* of the architect. It was assumed, indeed, that the architect knew what he wanted, and would not require the contractor to do more than he agreed to do under the contract. But the framers of the new schedule have given the contractor the opportunity of discussing this point with the architect before doing the work, and of referring the question as to whether there is an excess to the arbitrator. The clause runs thus: "If the work shown on any of the details or the further drawings or details referred to in Clause I., or necessary to comply with any instructions, directions, or explanations which may be given from time to time by the architect, be, in the opinion of the contractor, in excess of that comprised in the contract, he shall, before proceeding with the work, give notice in writing to this effect to the architect. In the event of the architect and contractor failing to agree as to whether or not there is any excess, and of the architect's deciding that the contractor is to carry out the said work, the contractor shall accordingly do so, and the question whether or not there is any excess, and if so the amount thereof, shall, failing agreement, be settled by the arbitrator, as provided in Clause 32, and the contractor shall be paid accordingly." As Mr. Cates has pointed out, this clause throws on the contractor the obligation to give notice before proceeding with any work he may deem to be an excess; and it is objectionable, also, because it takes away the architect's power of deciding whether a certain detail is an extra, and vests it in the contractor, who is to decide whether a thing is in excess or not, before proceeding with the work. This is certainly a concession to the contractor. No extra is to be allowed unless executed under clause 5 or by the architect's authority. The old clause provided that in cases of daywork all vouchers are to be delivered to the architect or clerk of works during the week following the work; the new schedule deals with extras in clause 13, in which it is stated that all "authorised extras" for which a price may not have been agreed, and any omission with the architect's knowledge or subsequently with his written sanction, is to be measured and valued (by the architect, or a surveyor appointed by him, and approved by the contractor), and a copy of such valuation to be given to the contractor. The fees for so measuring and valuing to be added to the contract sum. But if in the architect's opinion the work cannot be properly measured and valued, day prices are to be allowed, and vouchers specifying the time and materials are to be delivered to the architect or his nominee at or before the expiration of the week following the execution of the work; the valuation to be made at the rates in the contractor's original estimate, or at "rates proportionate to those prices." The old clause was to the effect that the variations were to be based on a schedule of prices, or, where same did not apply, at "fair measure and value."

Clause 15 of the amended schedule is practically the same as the old rule No. 8, and is to the effect that unfixed materials, when taken into account in any certificate of the architect for which the contractor has received payment, are to become the property of the employer, and shall not be taken away; and the contractor is to be liable for any loss or damage to materials. The next, clause 16, gives power to the architect to order the removal of improper materials and workmanship at the contractor's cost, and is a recasting of the old clauses 9 and 10. In default, the employer has power to pay other persons to carry out the same, the contractor to bear expense. A very important clause is the next (17), referring to defects after completion, and is an amplified form of the old clause 11. It provides that if any "defects, shrinkage, and other faults" are found within —— months after completion, arising, in the opinion of the architect, from non-compliance with the drawings and specifications or his instructions, or any damage to pointing by frost, they shall, upon his directions, and within a specified reasonable time, be made good by the contractor at his own cost; in case of default, the employer may make good such defects, and all the expenses be borne by the contractor, and shall be recoverable from him, or may be deducted from any moneys due. Defective work done by any sub-contractor who has been nominated or approved by the architect is to be made good by the contractor. Clause 18 provides that at the architect's request, the contractor shall "open for inspection any work covered up," and if the latter refuses or neglects to to do so, the architect may employ other workmen to open up. The contractor is to bear the expense of any work covered up in contravention of the architect's instructions, or which is discovered, on being opened out, not to be in accordance with the drawings and specifications; if it has not been covered up in contravention of his orders, and is found in compliance with the drawings, then the expense to be borne by the employer. The new schedule is more explicit as to sub-letting or sub-contractors. The old rule that the contractors are not to sub-let the works, or any part thereof, without the consent of the architect in writing, is still enforced in clause 19; and the next clause states that no sub-contractor nominated by the architect shall be employed upon the works "against whom the contractor shall make what the architect considers reasonable objection, or who will not enter into a contract with the contractor guaranteeing the due performance of his work," and indemnifying him against any claims arising out of misuse or neglect, and which may be brought against the contractor in consequence of any such default. This condition seems to be a reasonable one, and will protect the contractor against any act or omission of the sub-contractor; it will also remove the only serious objection which the contractor has to sub-letting. The contractor is to be held responsible for all structural and decorative damage, and for injury to persons, animals, or things, also for all injuries to the buildings by frost or bad weather. In respect of insurance (clause 22) one or two alterations are made. The old condition required the contractor to insure the building against fire in the joint names of employer and contractor for half the value of the works executed until it is covered in, and thenceforth till completion in three-fourths of the amount of such value, and is, upon request, to produce to the architect the policies and receipts of premiums. The present schedule requires the contractor (*a*) to insure, and keep the works insured until they are delivered up, in an office approved for the full value of the works executed, and to deposit with the architect the policies and receipts for premiums, or in default, the employer may insure, and deduct the premium paid from any moneys due; or (*b*) the whole building is to be at the sole risk of the employer as regards any loss or damage by fire, and in case the original building, in addition to the new work, is affected, the contractor is to be entitled to receive the full value of all work executed, calculated as provided by Clause 13. This last alternative applies to a building in course of alteration. The clauses referring to non-completion and extension of time have been revised. The architect is to have power to make a fair and reasonable extension of time in certain cases —as on account of inclement weather, by reason of proceedings taken or threatened, by disputes with adjoining owners, by extras, by local combinations of workmen or strikes. A very long and verbose condition is No. 26, which provides against any suspension of works by contractor without sufficient cause in the opinion of the architect, except on certain grounds which are specified. In such a case, or if the contractor neglect, or fail to proceed, or shall more than once make default in the respects mentioned in clause 15, the architect is empowered to give notice to the contractor to proceed with the works. This notice is to specify the act or default on the contractor's part upon which it is based. After this notice, the contractor is not to be at liberty to remove from the site or works any plant or materials which have been placed thereon for the purpose of the works, and the employer is to have a lien upon all such plant and materials to subsist from the date of such notice being given until the notice shall have been complied with. The employer may enter and take possession of the works and site, if the contractor fails to proceed with work, also the plant and material, and he may engage other persons to complete the works, and exclude the contractor or his agents from entry; other directions follow as to the course to be pursued in completing the works, adjusting the expenses, &c.

The new arbitration clause (32) which forms the last in the schedule, is much modified in the wording. Under the old form, any question, dispute, or difference, except certain matters left to the decision of the architect under certain clauses, is to be referred from time to time to the arbitration and final decision of ——, architect, or in the event of his death or unwillingness to act, then of ——, or of an architect, being a Fellow of the R.I.B.A., to be appointed on the request of either party by the President, &c. The new clause is practically the same, and leaves the matter in dispute to be decided by someone, as before; but the word "architect" is omitted in the first instance. Such reference, except on the question of certificate, shall not be opened until the completion of the works, unless with the consent of the architect and contractor. The arbitrator is given power to open up, review, and revise any certificate, opinion, decision, requisition, or notice, except in matters under clauses 4, 9, 19, and 18, and to determine all matters in dispute, and he is to determine the costs of the reference and award, and direct by whom and to whom, and in what manner, the amount shall be borne and paid.

The Institute of Builders have framed an arbitration clause of greater length, in which they categorise in more detail the various questions of differences likely to arise. The words "or after an entry under clause 23" are inserted after the words "either during the progress of the works." Under sub-clause (*a*) the questions in disputes are to include "the right exercise, and the exercise of the architect or the employer of any power conferred upon them (except those under the sole direction of architect under clauses 3, 8, and 17), and the right to have work opened up under clause 16"; (*b*) the withholding by the architect of any certificate or decision, &c.; (*c*) the nature, terms, and reasonableness, or otherwise, of any certificate, decision, requisition, or opinion of the architect, and the time of the giving thereof as to which the contractor shall be dissatisfied; (*d*) as to what additions (if any) ought, in fairness, to be made to the amount of the contract by reason of interference, delays, &c., through no fault of the contractors, or by reason of any decision, direction, or requisition of architect, or failure on his part to give any decision involving increased cost to contractor; (*e*) any claim by the contractors for work done, or goods supplied, though outside the contract, &c. It seems to us a pity these forms of arbitration clause could not have been reconciled in the interests of both architect and builder.

The more elaborate form of contract thus substituted for the "Heads of Conditions" has its advantages as well as disadvantages; it can be used in its entirety if so desired; on the other hand it will scarcely be so useful for reference to architects who make their own conditions. Some of the clauses of the old form were out of date, and the Bankruptcy clause was said to be illegal as framed. These were reasons for a revision. On the other hand, as Professor Roger Smith said in the discussion, the old conditions had been approved by the Institute of Builders, who were willing to adopt them, and it was a great advantage to be able to produce a document which had the sanction of the Institute, and also the advantage of being officially accepted by the builders. Some definitions and conditions were absent. The term "prime cost" has been defined as being "the sum paid to the merchant after deducting all trade discount for such goods in the ordinary course of delivery, but not deducting discount for cash, and such sum shall be exclusive of special carriage, the cost of fixing, and contractor's profit." Provision also has been made for "provisional sums" for work to be done by special artists and tradesmen, and fittings, these being left to the architect's discretion. Again, a clause is introduced relating to the use of plant and scaffolding by the sub-contractor. These are necessary additions to a building contract.

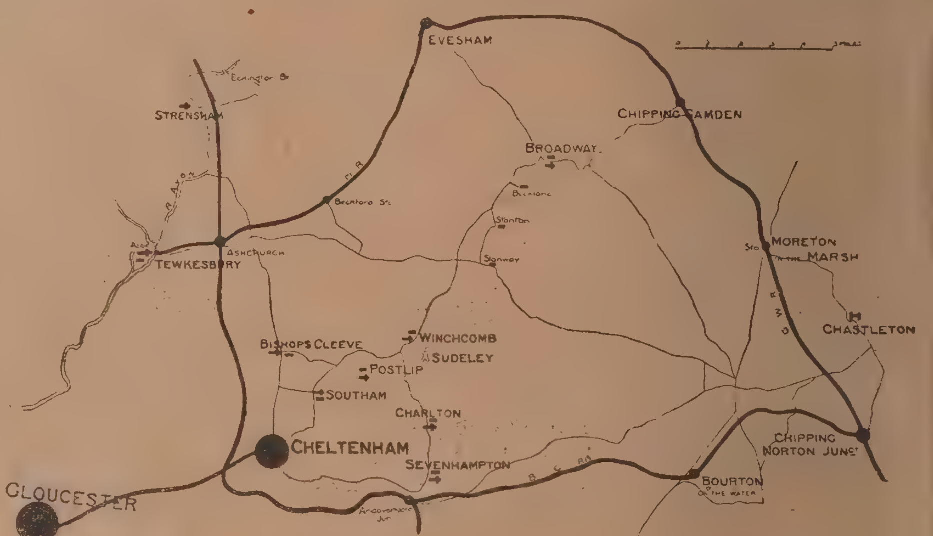
GENERAL BUILDING LINES.

THE important decision which has been given in the Court of Appeal by Lords Justices Lindley, Lopes, and Rigby on the powers of the superintending architect, in the case of "Allen *v.* London County Council," will set at rest those disputative persons who are always trying to find a loophole for escape from the provisions of the Metropolis Management Act, 1862, section 75. The general question, as shown in the full reports we gave, pp. 33, 174, was whether the decision of the superintending architect is binding as to the general building line in a street, but also as to the question in which street or road a particular house located at the corner of two streets is situate, for the purpose of determining the building line. The magistrate before whom the case was first brought ordered the demolition of a certain building as beyond the building line, but who stated a special case. The plaintiffs had begun to erect a building beyond the general line of buildings on the north-western side of Birchington-road, Kilburn, without the consent of the L.C.C., contrary to section 75. The buildings in question were shops and houses at the corner of the said road and Kilburn High-road; there was a frontage of 58ft. to Birchington-road, and of 22ft. to Kilburn High-road. The former frontage extended 16ft. beyond the line of buildings as determined by the certificate of the superintending architect, who stated that the main fronts of buildings in a certain row of houses formed the general line of buildings on the north-western side of Birchington-road, "in which road the building in question is situated." The plaintiff denied this: he contended that the architect, by his certificate, had not found that the building was situate in the "street, place, or row of houses" described, and that he had placed the building in a "street, place, or row of houses" in which the same was not situate.

The questions before the Court were:—(1) Whether the certificate showed that the houses in question were situate in the street, place, or row, and for which the general line was determined? (2) Whether it was the duty of the architect to decide and find the situation of the plaintiff's building, and if so, whether his decision was binding on the magistrate? The Divisional Court decided in the affirmative, and the plaintiffs appealed. The Court dismissed the appeal, and Lord J. Lindley was of opinion that the certificate did decide the plaintiff's house was in Birchington-road. As to whether it was under section 75, to be decided by the superintending architect or the magistrate, his Lordship laid down in categorical order what were the circumstances necessary to justify an order for demolition under this section. The following seem the most important: the building, structure, or erection must be in some street, place, or row of houses; these must have a general line of building; this line of building of the street, place, or row of houses in which the building complained of is situated must be decided by the superintending architect; lastly, the building, structure, or erection must be erected beyond the line so decided. The judge continued: "What is left to the decision of the architect is the existence and exact position of the general line of buiding of the street, place, or row of houses (if any) in which the building, &c., complained of has been erected. In case of dispute, the magistrate must decide all the other matters referred to—e.g., whether the building complained of is one to which the section 75 applies, especially having regard to section 74; whether the necessary consent has been given; whether the building, &c., is in a street, place, or row; whether it has been erected beyond the general line of buildings of that street, &c., as decided by the architect. Such, in my opinion, is the true interpretation of the section and of the decision in 'Spackman v. Plumstead Board of Works,' which set at rest the doubt whether the magistrate could review the architect's decision as to the general line." As to the question who is to determine whether the building complained of is in the particular street, place, or row to which the architect's certificate is applicable—on this point his Lordship agreed with the decision of Lord Herschell's judgment, and with the opinions of Lord Watson and Lord Fitzgerald (in Barlow's case), and he thought the architect, rather than the magistrate, was the proper person to say to what line of building a particular house should conform. The following remarks are to the point, and deserve emphasis:—"The architect might, no doubt, assume, without deciding, that the building complained of was in a particular street, place, or row of houses, and simply certify the general line of buildings of that street, &c., leaving the magistrate to determine whether, after all, the building was in the street, &c., to which the certificate applied. But this would be to deprive the architect's certificate of half its value, and the interpretation which leaves him to decide what building line is to be conformed to seems to be preferable to an interpretation which leaves that question to the magistrate." On these grounds the appeal was dismissed. This decision will settle the question of jurisdiction, and will dispose of those vexatious quibblings and technical points which are often raised by building owners. In the case of "Barlow v. Vestry of St. Mary Abbotts, Kensington," Lords Watson and Fitzgerald decided that the architect was the person to determine, though Lord Bramwell held it was the magistrate. In the future the proposed tribunal of appeal will determine cases of this sort when the architect's decision is disputed. There has always been hitherto a divided jurisdiction, which litigants in these matters take advantage of. The magistrate is appealed to against the decision of the L.C.C. or their officials, or if his decision is unfavourable, an appeal is made to a higher Court, and these appeals are often successful in reversing the decision of the magistrate, and in weakening the authority of the statute. Section 22 of the new Act, which re-enacts section 75 of 25 and 26 Vict., referring to the general line of buildings, states: "Such general line of buildings shall, if required, be defined by the superintending architect by a certificate, such certificate to be issued within one month from the date of the application therefor." Nothing seems plainer than this.

THE ARCHITECTURAL ASSOCIATION EXCURSION, 1895.—I.

[WITH PHOTO-LITHOGRAPHIC AND OTHER ILLUSTRATIONS.]



THE accompanying plan, kindly furnished by the senior hon. sec. of the Excursion party, Mr. H. D. Searles-Wood, gives a very good idea of the extent of the district, mainly situated in Gloucestershire, which will be visited next week, with Cheltenham as a head centre, at "the Queen's," and the following is a copy of the official programme:—

Monday, August 12.—Southam House, pigeon house, farm, Norman chapel, manor house farm, barns, &c; Bishop's Cleeve, church, old houses, &c.; Postlip, manor house, chapel, barns, &c.

Tuesday, August 13.—Tewkesbury, abbey and old houses.

Wednesday, August 14.—Chastleton manor house, and new house, Batsford.

Thursday, August 15.—Broadway, church and old houses; Buckland, church and old houses; Stanton, church and old houses; Stanway Hall, church and old houses.

Friday, August 16.—Sevenhampton, house and church; Charlton Abbots, house and church; Winchcomb, church, Jacobite House, old houses; Sudeley Castle.

Saturday, August 17.—Gloucester, cathedral, old houses.

We give to-day the first of our series of sketches in illustration of the more characteristic buildings to be seen during the week, among our contributors being Messrs. C. E. Bateman, A. J. Dunn, the Pugin Travelling Student of the year, J. A. Gotch, F.S A, the author of "The Architecture of the Renaissance in England," and C. E. Mallows.

The first item on the programme is the "pretty mannour place bilded at Southam by Sir John Huddleston" in the days of Henry VII., close to the main highway going north to Pershore, some two and a half miles from Cheltenham, on the rising ground towards Cleeve Hill, from whence an exceptional view is obtained, embracing the vale of the Severn, bounded by the Malverns, Welsh Mountains, and Forest of Dean. Here at Southam and Bishop's Cleeve some considerable time is to be devoted to sketching. Southam House, built of timber and stone, has an uncommon Tudor bay window, two stories high, with traceried heads to the lights, characteristic of the Perpendicular period, and inside the same parlour is a good Jacobean oak chimneypiece, with oak wainscoting round the room. There are several smaller oriels of old date, but the tower is modern. The building is a venerable structure dating from 1501, and retains more of its original form than, perhaps, any contemporary house of its class. It is constructed of two stories only, without a parapet. The three principal apartments appear to have been finished, as they remained till within a few years ago, and the various alterations effected are all of recent date. One of the halls was paved with glazed or encaustic tiles brought from Hayles Abbey. Nash made an excellent drawing of one of the rooms, and it will be found lithographed in his "Mansions of the Olden Time." In the windows are the arms and cognisance of Henry VII., for whom Sir John Huddleston made his survey. The property passed by marriage to the now extinct family of De la Bere, who fought at Hastings and Cressy.

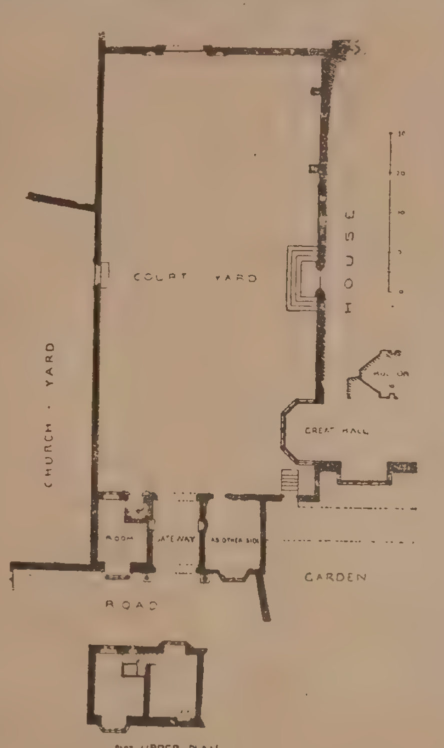
On the return journey from Bishop's Cleeve, Postlip, an ancient mansion erected in the 16th century will well engage the attention of the party. It was erected by a member of the Broadway family, whose arms are carved in oak and stone about the building. The house contains a large oaken wainscoted room divided out into bays, with richly-treated pilasters surmounted by a carved frieze, and resting on a panelled dado plinth of good proportions. The ceiling is in character; but the chief feature of interest in the gallery is the florid Jacobean chimneypiece which has statues of females at either end in niches, and having recumbent figures of children at their feet, almost serving as corbels to support them, making a curious arrangement. Joseph Nash made a careful study of this room, which appears in his great book before mentioned.

On Tuesday, Tewkesbury will occupy the greater part of the day, the afternoon being spent by a steam-launch trip up the Avon, passing Strensham Church, where there are some fine old oak seatings and a rood-screen fixed at the west end, with curious figure paintings and some well-preserved marble monuments to the Russells. We shall publish next week some views from the Abbey and old timber houses to be seen in the ancient streets of the town. When the Associationists visited Tewkesbury in the Worcester excursion in 1881 we published a view and plan of the Abbey besides some sketches of domestic work near to hand by Mr. Sydney Vacher, and on October 26 last a good view of the famous mediæval bridge at Tewkesbury appeared in our pages, with a photo-print of a most picturesque coved penticed old shop at Berkeley, a town too far south for the present outing, and described by Leland as "no great thinge, but standythe well and in a very good soyle." Its castle, however, is of more than ordinary consequence.

On Wednesday, a rather long railway journey to Moreton-in-the-Marsh starts the proceedings, after which half-an-hour's stay will be made at "Batsford," a fine new house erected for Mr.

A. B. Freeman-Mitford, C.B., by Messrs. Ernest George and Peto. We illustrated the Hall in the Building News for Jan. 4, 1889. Externally the house is executed in stone, and well harmonises with the historic architecture of Gloucestershire. The greater part of the day, however, is to be devoted to Chastleton House, which stands on the western borders of Oxfordshire, where it adjoins Gloucestershire, and not far south from Moreton-in-the-Marsh. We now give two views of this lichen- and moss-covered stone building, of which a larger and more detailed sketch appeared in our pages for May 12, 1893, from the pencil of Mr. E. Guy Dawber. Other views with plans figure in Gotch's "Architecture of the Renaissance in England." To the front of the house there is an entrance-court approach through a plain gateway. Formal gardens extend on either side, enlivened by trees and shrubs sufficiently encroaching upon the rigid lines of the garden scheme to afford room for one's fancy, without impairing the intentional limitations of the designer, whose aim, rightly enough, sought to assimilate the immediate preludes of the mansion with its architectural treatment. On the remaining side are the stables and kitchen-court, while the plain old church hard by adds to the air of unchanged antiquity distinguishing the place, which is so charmingly devoid of any idea of looking smart and up-to-date in character. Some historic and other particulars, with a view, accompanied by plans contributed by Mr. Jethro A. Cossins, were published during 1888-89 in the *Transactions* of the Archæological Section of the Birmingham and Midland Institute, and are reproduced here, by permission, for reference. Inside the house the same character is maintained, though not a few of the rooms certainly have been denuded of their ancient ceilings and woodwork. There have been but few if any structural alterations, and the plan of the building remains very nearly what it must have been when the house was erected originally. The oak screen and daïs stand in the hall, and the little parlour has its old arched Jacobean panelled walls and a good plaster frieze. Upstairs the "Great Parlour" retains its antique chimneypiece, and richly-panelled walls, and ornate ceiling. Among the bedrooms some very good ceilings and chimneypieces are to be seen, besides panelled or tapestried walls; and as for specimens of old furniture, it may be said that the house is a veritable museum, not to mention the bed hangings and counterpanes which are said to be as old as the house, and can be identified by the "Inventory" of the goods and chattels in the house in the year 1633. Some of the ancient jewelry depicted in the family portraits still is treasured by the present owner of Chastleton, Miss Whitmore Jones, who is descended from the builder of the mansion. He was one Walter Jones, who bought the estate in 1602 from the Catesby of Gunpowder Plot celebrity. The building works were commenced without delay, and finished in 1620. The site is described as having been once occupied by an earlier house of the Catesbys, while some of the foundations of the older house are thought still to stand. It is not an uncommon mistake, however, says Mr. Gotch, to date pillars and vaulting of the beginning of the 17th-century a hundred years or so too early, and there is little doubt that the cellars of Chastleton are coeval with the work above them. The kitchens in the basement retain much of the old furniture and cooking implements, including a large service of old pewter. The house is built round a small court, which affords a certain amount of light and air; but these small courts, surrounded by lofty walls, are difficult to make cheerful, and nothing that is desirable will grow in them. It is only the outer walls of the house that are of stone, all the partitions are of oak framing covered with lath and plaster; but they serve their purpose quite well. There are two staircases—one old and one new; but the old one is built round a solid core, or, at any rate, the walls of it are solid, and it only breaks out into newels and balusters on the top floor. It is on this floor, along the north-west front, that the long gallery extends from end to end at the rear of the house. It has a fine ceiling and panelled walls, but is rather low, and is not now in use. The drawing-room—the original Great Chamber—is a handsome panelled apartment, with a rich plaster ceiling and a good stone and marble chimneypiece. The great hall is an interesting room, as it retains its original screen and daïs, but the screen itself is not particularly good in design. The general aspect of all the rooms is no doubt unusually attractive. The builder, Walter Jones, a Royalist, died in the year 1632, and an inventory of the whole of the house and the effects in the house at that time, as already mentioned, is preserved there, giving the names then in use for the several apartments, such as "Mr. Fettyplace his chamber," wherein is the bed with a taffeta quilt upon which Queen Elizabeth slept at Woodstock, so that the rooms can always be readily identified. The arrangement of the front entrance is very like that at Burton Agness in Yorkshire, and other houses in the West of England, but the doorway in such a position is unusual.

Broadway, in Worcestershire, is to be the northernmost point in the programme on Thursday, and next week we shall give some sketches of some of its typical old stone houses, which line the wide, straggling village street in which the Lygon Arms, with its rather good Elizabethan-like doorway, dated 1620, forms a conspicuous and hospitable feature. Luncheon is to be served for the visitors in this historic hostelry. The wide highway gives the name of Broadway to the place, which now has more the character of "a deserted village," though at one time it was a town of some consequence. Charles I., for instance, is said to have rested at the Lygon Arms on several occasions during the Civil Wars. The old houses are for the greater part very plainly treated; but obtain a degree of character from their mullioned windows and quaint gables, and the Manor House of the Abbey of Pershore, the most elaborate of them all, has only the addition of cusped openings to the fenestration. The old church, a mile south of the village, is now used as a cemetery chapel, and is of various periods of work, with a Late square, central tower, and turret rising from the east wall of the north transept. The absence of buttresses has been pointed out as a notable feature, giving breadth to the wall surfaces of the little building. Buckland, next to be seen, has some similar old houses, among which most worth naming is the 14th-century rectory, partly dating about 1520, with a hammer-beamed roof-truss over the old hall, and a gallery-front in half-timber. Near by is another house of Edwardian character, built by the abbots of Gloucester, with a big fireplace in its hall, over which is an original roof. The church is not a large one, and is chiefly attributed to the 13th century, with a plain, embattled tower marked by demoniacal gargoyles at the angles. There is some ancient glass in the east window in representation of the sacraments of Baptism, Matrimony, and Extreme Unction. The tie-beam roof is decorated with the white rose of Edward IVth. A curious canopied pew has to be noted as long time a feature in the interior, and a 15th-century cope for many years served as a frontal to the altar. Stanton village, of which we give an accompanying sketch among our photo-lithographic plates, has an old cross and some nice roadside houses, while the church, being unrestored, becomes consequently an object of uncommon interest.



STANWAY

PLAN OF COURTYARD

The last place to be visited on Thursday is Stanway Hall, which is situated in Gloucestershire. Of this house, belonging to Lord Elcho, we give the annexed plan, at once serving to explain the disposition of the various features in this old mansion, which is one of the most striking examples left of a really fine architectural treatment of a forecourt. We are indebted to Mr. Gotch for permission to give the accompanying details, drawn by him and his coadjutor, Mr. Talbot Brown, for their famous book on the "Architecture of the Renaissance in England," which Mr. Batsford published with so marked a success a few years since. The view of the courtyard which we have herewith drawn forms one of the plates in the same volume, from the pages of which the following descriptive account of the building has, with consent, been utilised. The entrance to the courtyard is beneath an imposing gatehouse, upon passing which the long front of the house is seen on the right; an inclosing wall extends on the left, and is broken by a charming doorway, opening on to the churchyard immediately opposite to the front door of the house. We give a detailed drawing to scale of this feature, and Mr. Bateman's sketch on another plate herewith shows the doorway exactly as it comes in the wall, with the parish church beyond. The fourth side of the courtyard is inclosed by a wall, in which there is another imposing archway leading to the stables, which are discernible in the distance. There is no particular effort apparent, unless it may be in the gatehouse; but the whole effect is striking and stately—the result, be it noted, of simple but skilful planning. It is said to have been designed by Inigo Jones, and the character of the work bears out the supposition, in the opinion of Mr. Gotch, for, as he says, very rightly, although thoroughly Jacobean in its general appearance, much of the detail looks somewhat later, particularly the elliptical windows on the inner front of the gatehouse. The house itself has been considerably modernised and enlarged, and what detail is left is of a plain character. The great bay window, shown by the accompanying view, is the most noticeable feature, and of this it must be confessed that its size forms its chief claim to attention, the detail being meagre, and the whole effect rather fragile. These defects, however, only appear on a close scrutiny; the first impression conveyed by this great bay in connection with the gatehouse and inclosed court is one of much stateliness. The history of Stanway, so far as it concerns an architectural descriptive account such as we need only concern ourselves with, is soon told. The estate belonged to the Abbey of Tewkesbury till the Dissolution, when it was given to one William Tracey. He settled it on his second son, Richard, who married Barbara, a daughter of Thomas Lucy, of Charlecote, near Stratford-on-Avon—the Lucy whose deer Shakespeare is said to have killed, and who will for ever give delight to the world as Justice Shallow. Richard Tracey was succeeded by his son Paul, who was made a baronet in 1611, and it was Sir Paul who built the house. Possibly he may have had his mother's home in view when he built his own, for at Charlecote, too, is a gatehouse, but not so fine a one as here. Sir Paul died in 1626. The Traceys were important people, and, no doubt, worthy of their fine home. The title became extinct on the decease of the fifth baronet in 1677. In old days there used to be grand formal gardens here "and a cascade of water seen from the vale below at a distance of several miles." Atkyns, in his "History" of the county, gives a good view of the old arrangements, which have since been quite altered. The gardens, however, are still very attractive. There is a tithe-barn in the grounds formerly attached to the Abbey of Tewkesbury and now used as a tennis-court. The property descended to the Earl of Wemyss on the marriage of his grandfather, Lord Elcho, with the eldest co-heiress of Anthony Tracey, and the mansion is now occupied by the present Lord Elcho, the late member for Ipswich. There is an uncommonly large cedar in the gardens, and an extensive panorama is obtained over the vale of the Severn. The Tudor church has a quaint square tower rather more rich in style than many others of greater size in this district. The nave and chancel are of some little interest, and the group of buildings add much to the beauty of the sylvan scene.

Next week we shall continue our illustrations, and conclude the descriptive particulars of places yet to be noted on the programme, including Gloucester, which is to be seen on the last day of the excursion under the guidance of Mr. F. W. Waller, F.R.I.B.A. The sketch given to-day gives a capital idea of the cathedral. It is drawn from a new point of view by Mr. Alfred J. Dunn. The original from which our plate is taken formed part of the series of studies for which he was awarded the Pugin Travelling Studentship last winter. We gave his National Gold Medal drawings of the cloisters at Gloucester in the Building News for Nov. 9, 1894.

THE INTERNATIONAL HEALTH EXHIBITION AND CONGRESS, PARIS.—III.

On the following morning, July 9th, the Congress entered into a lengthy discussion on the construction and drainage of houses, this being followed up by a paper on the arrangement of the dwelling and its internal accommodation, read by M. A. de Baudot, Government architect, and lecturer at the Trocadero. M. de Baudot is an earnest advocate and practical originator of the rational methods of design and construction, his opinions being that architects have not progressed with the age, their buildings of the present day being nearly similar to those built a century or more ago, instead of being, as they should be, striking examples of an evolution naturally brought about by the rational use of the many new materials of the age, and fitness to the present style and necessities of everyday life. This architect has followed up his theories with practical work, his own private house in the Rue de Longchamp being built and arranged according to his ideas, the main features of the construction of this original and comfortable dwelling being the free use of iron, cement, terracotta and ceramic ware, hollow walls constructed after a special system of iron and cement, providing all conveniences for heating and ventilation. The following is a free *résumé* of M. de Baudot's paper before the Congress, giving the chief points of his recriminations against architects and builders of to-day. In our days, he says, the sanitary conditions of the dwelling have been much improved, thanks to a more reasonable planning and the utilization of apparatus due to sanitary science and industry; but there is yet much to be done in order to make the arrangements perfect, and to put them economically within reach of all.

It is true that in luxurious dwellings, in the public buildings of large towns, a certain measure of success has been attained in securing sanitary results relatively satisfying; but in our middle-class houses, and especially in workmen's dwellings, in cheap flats, in secondary public buildings, in many of our schools and colleges, in workshops, a proper satisfaction to legitimate demands, and action precisely where the public health is most interested by reason of the accumulation of human beings, is almost impossible. Indeed, it is not sufficient to have modified the planning of dwellings, to have increased the cubic space of air, to have permitted light to penetrate more freely; that which is necessary to-day is the introduction of what is lacking—viz., rationalism and economy in manner of construction, the arrangement of the skeletons of our buildings according to the dictations of rational constructional science, and the necessities of sanitation. Unless we arrive at a radical transformation in this direction, we shall never obtain anything better than very indifferent and expensive arrangements for heating and ventilating our dwellings, or mediocre conditions of working, economy and durability in the installation of the apparatus destined to rid us of waste water and house refuse, the carrying away of which gives rise to so many difficulties and so much expense.

Again, going further than this, is it not evident that the present manner of construction employed in our dwellings does not obey even the most elementary laws of sanitation? Is it not evident that builders are inspired more with the idea of pleasing the eye than with that of economy and giving us protection against the variations of temperature? For example, is it not a striking fact that, especially in our large towns, whilst all walls which can be seen from the street, be it mansion, flat dwelling, or public building, are persistently constructed of massive stone with excessive thickness, those at the back, giving on the courtyards, are built of flimsy brickwork of slight thickness or even of still thinner iron framing and brick? In these buildings we find on one hand a complete absence of rationalism, and on the other hand a complete neglect of sanitary principles. The cause of inequality of temperature in the various portions of the same apartment is even more noticeable, because no account whatever is taken of the ventilation of the walls, of whatever thickness they may be. In these same dwellings, is not a complete sacrifice made of the comfort and health of the dwellers in the roof story, the portion whose thin and imperfect covering affords very indifferent protection from the exterior temperature, in winter as in summer?

Many remarks also may be made concerning the floors, and regret be felt that the filling between the iron floor-joists is too often formed of plaster coming from demolished buildings, and from this reason possibly often containing noxious germs. Besides, in this style of floor the dead-weight is too considerable, necessitating joists and girders of excessive strength, and consequently useless expense. If we leave the question of the construction of vertical surfaces (walls), inclined surfaces (roofs), and horizontal surfaces (floors), and come to examine the manner and arrangement of the ducts for heating and ventilation purposes, and the various kinds of apparatus for water, gas, and electricity, is it not evident that no proper forethought has been made during the study of the planning for the arrangement and fitting up of these indispensable accessories? The result is an incomplete or insufficient installation, unsatisfactory working, and much expense for repairs. It is very often the case that for this reason we are led to employ heating apparatus producing overheated air and unhealthy gases, to neglect the proper arrangements for ventilation, to give a too hasty attention to flushing reservoirs and sanitary apparatus, the outcome being a general condition of unhealthiness in the dwelling, an irregularity, insufficiency or superfluity of warmth, a lack of fresh air, and the inconveniences of frozen siphons and down-pipes.

On looking at the many requirements of the present day, requirements which did not preoccupy the attention of our predecessors, it is difficult to understand how it is that these errors exist, the more so at a time when the science of building and industry comes to the front and offers us all the things which we neglect and important aid in the construction of dwellings of all kinds answering in all ways the necessities of the modern programme.

The consideration and study of this programme, the discussion and study of the proper means, systems, and materials, the guiding of the architect in the new and difficult road he has to follow to-day—such are the important questions which he submitted, maintaining, however, that in order to better the arrangement and fitting up of dwellings the system of construction and general economy must be first and entirely transformed.

M. de Baudot conducted the members of the Congress over the buildings of the Lycée Victor Hugo, Rue Sevigné, and was there able to put his theories to a practical demonstration; the building is from the designs of this architect, and constructed according to his ideas of the rational use of the materials of to-day, containing also the many conveniences of various kinds arising from this manner of construction.

A lengthy paper on house-drains, read by M. L. George, architect, brought forward a number of resolutions regarding the proper ventilation and trapping of soil and other pipes, concluding with a vote that a complete study be made of the well-known and practical systems employed in England. An interesting resolution was to the effect that the surrounding of traps, down-pipes, and flushing cisterns with some non-conducting material affording secure protection from the frost should be insisted upon. This important question forms the subject of much attention at this moment. An interesting report lately read by M. Masson, sanitary inspector for Paris, urging that some such protection be adopted for all hydraulic apparatus liable to attack from frost, was made with the special intention of answering the objections brought up by a large number of architects and engineers who condemn the flushing drainage system as one offering too grave inconveniences in winter time, owing to the freezing of the canalisations, cisterns, down-pipes, and siphons.

The question of compelling sanitary plumbers to pass an examination and obtain proper diplomas was discussed, Mr. E. Tidman, secretary of the British Sanitary Inspectors' Association, explaining that in England the British Sanitary Institute awarded diplomas by examimation, and that examiners were sent by the Plumbers' Company to various parts of the country for the purpose of examining in theory and practice all intending sanitary plumbers. It was to be desired that shortly no plumber would be permitted to execute sanitary work unless he could produce his diploma showing that he was fully qualified. M. Masson, aforesaid, replied that two schools of sanitary plumbing had been established at Paris, and brevets were given to those who passed a satisfactory examination after three years' training. A final resolution was passed by the Congress deciding that every encouragement should be given to such schools, and that certificates of capacity should be awarded to workmen plumbers who could show full competence in their work.

The point being raised regarding the width of streets compared with the heights of houses, brought up from M. Charles Lucas, secretary to the Architects' Mutual Defence Fund, the remark that they, as hygienists, would be constantly obliged to vote in favour of what, as architects, they would have to fight against. Mr. Adolphe Smith argued that it was not their business to consider any special professional interest. A hygienist should know something of medicine, chemistry, architecture, engineering, plumbing, and other handicrafts. As regards localities, what was expedient or practical in any one town or place was not to be specially considered, but a general principle which all localities should endeavour to realise when practicable. The principle in this case, he considered, was that the direct rays of the sun should reach the windows of all buildings once in a day. M. Bechmann, chief engineer of the town of Paris, considered that this was not practicable, M. Cacheux, engineer of the Society for the Creation of Cheap Dwellings, arguing greatly in favour of direct rays of sunlight for all inhabited rooms. The Congress, however, considering the ideal of the hygienists to be impracticable, did not pronounce any decided opinion on this matter.

M. Morin-Goustiaux, vice-president of the Commission on the Unhealthy Dwellings of Paris, read a paper on the necessity of an efficacious control over the sanitary arrangements of dwellings. He stated that a certain number of precautions had been taken against the dangers accompanying the use of gas in dwellings, but up to the present little thought had been given to the dangers arising from the gases contained in the waste water and other drain-pipes which cross the dwellings in all directions, and that the care of the public health exacted that similar precautions be taken for general plumbing work. That there is no service for the inspection of drainage work, the Commission of Unhealthy Dwellings making a few visits, but only when cases are signalled; the result is that the builder in very many cases does exactly what he likes, and very often his ignorance of the most elementary rules of sanitation is absolute. He quoted very fully a number of the regulations enforced in America by State laws, explaining the system of the inspection of work during the course of execution, and the complete collection of documents and plans, making a detailed register of all work done in every street and every house at Chicago and other large cities. After reading the formidable list of rules and regulations enforced by the gas companies, and expressing the desire that such rigorous regulations existed for sanitary work, M. Goustiaux presented several resolutions asking that the rules relating to plumbing work be made as uniform as possible for all towns, whatever be the manner of drainage; that all plans for drainage be submitted to and examined by a competent authority before the commencement of the work; that no drains should be covered over before being properly examined, and an inspection and test made of the various apparatus; and that, similar to the custom in the United States, all contractors for sanitary work should be licensed by the town authorities. These resolutions were adopted by the Congress.

M. Charles Lucas read a paper on the exterior and interior sanitary arrangements of cheap dwellings. These dwellings, he said, consisted either in blocks—viz., houses with several stories comprising a more or less large number of dwellings, and consequently a dense population—or in the shape of family dwellings—viz., small houses, either isolated or in groups, having at most one story, and inhabited by one family; that these dwellings deserved the closest attention of the Congress in point of view of the sanitary measures to be taken. He presented the resolutions, that, when planning such buildings, greater attention be paid to the orientation and the direction of the most frequent winds, in order to guard against, as much as possible, all bad smells, return of smoke, and inconveniences from frequent rain; that every care be taken to provide proper supply of drinking water and washing water, and the proper evacuation of drainage and house refuse; that for the construction of the outer walls—walls which, from reasons of economy, are often made very thin—a larger use be made of materials suitable for protection from both cold and heat, and which are, both as regards their nature and the manner of their jointing, impervious to damp. Regarding the internal arrangements for physical and moral comfort, the following should be carefully examined: the planning of the rooms and the reduction of their number as far as is possible, to enable the mother to watch over her often large family whilst attending to her domestic duties, and also to afford as much economy as possible in lighting and heating; the absence of mouldings, and the adoption of walls with rounded corners, leaving few angles liable to accumulate dirt, mildew, and insects; the preference to be given to oil-painted walls rather than papered walls, allowing thus a frequent washing, and avoiding the deposits of noxious germs; the installation of what could be called fixtures in the way of furniture, decreasing the inconveniences of little furniture, and avoiding the cost of transit for poor families, whose trade or occupation may force them to suffer frequent changes of dwelling.

A resolution urging that the Sanitary Bill, adopted by the Chamber of Deputies, and now before the Senate, should become law at the earliest possible date was unanimously passed; it was also resolved to facilitate as far as possible the creation of sanitary professorships in all the schools of architecture.

An interesting paper on the rational heating and ventilation of dwellings was read by M. Charles Gautier, president of the Society of Government Architects. The opinions of the reporter, given in a rather lengthy paper, may be summed up in the following. M. Gautier began by saying that not being a specialist in the question of heating and ventilating—an architect, indeed, having a very extended part to play had very little time to become a specialist in any matter—he would only give broad views of the various systems employed, with their inconveniences and advantages. Since 30 years great progress had been made in heating the dwellings of our large towns, and much praise must be given to those who were using their best endeavours to improve or replace the old systems, so often incomplete and insanitary. He would divide the matter into six sections, chimney-places, stoves, hot-air stoves, heating by hot water, by steam, and by a combination of hot water and steam. Taking first in order the question of chimney-places, M. Gautier said that the greatest enemies to rational heating of dwellings were fashion and pleasure to the eye; the ordinary chimney-place would never be dethroned, notwithstanding that it is an apparatus heating very indifferently, and affording an even worse ventilation; it has, however, one great advantage, that of considerable cheerfulness combined with an agreeable and artistic form, making it very often one of the most charming ornaments of the dwelling. This being so, the greatest success would attend the inventor of a rational heating apparatus maintaining the form and aspect of the beloved chimney-place; but the many endeavours which have already been made have not been successes up to the present. Again, the large mirror which is nearly always seen surmounting the chimney-pieces of our houses is the cause of a considerable loss of the heat given off by the open fire; if we could persuade the ladies to sacrifice their chimney mirrors, the heat-giving surface would be largely increased; the looking-glass could be advantageously replaced by an open coffer artistically ornamented, and allowing the use of special systems for utilising the heat which is at present wasted. The idea is not new, it is one of the applications of hollow walls advocated by M. Trelat, and other well-known names.

Next taking the question of stoves, M. Gautier said that the chimney fireplace lacking proper heating qualities, a large proportion of the heat being carried off with the smoke, a more efficacious means of heating was sought after, and the stove was invented. The stove might be divided into three categories—the simple stove, the hot-air stove, and the portable stove. The first may be said to give off greater heat than the fireplace; but the ventilation is almost nothing. For this reason, such stoves should be employed only in rooms ventilated in a manner independent of the heating apparatus. Again, these ordinary stoves, much employed on account of their cheapness and economy, are very injurious to respiration by reason of the over-heating, sometimes to redness, of the metallic sides, and this inconvenience has led to the construction of stoves encased in faïence and similar ware, which, whilst attenuating this inconvenience, has the advantage of allowing an artistic and elegant decoration. The hot-air stoves differ from the preceding only as regards the envelope of metal or faïence surrounding the central heating surface, a receptacle filled with water serving the purpose of moistening the heated air. The movable stove is a kind of reaction against the chimney place, which was first intended for burning wood for heating purposes. This combustible being now often beyond the limit of general means, an apparatus for burning the less expensive small coal, or even gas, became a necessity, and the movable stove, with continuous and slow combustion, easily moved from one room to another, and adapting itself to the various fireplaces of the dwelling, was invented. These apparatus, as a rule cheap, and requiring little attention, have much success; but, unfortunately, experience has proved that they are exceedingly dangerous, by reason of the abundant production of oxide of carbon which, when the draught is defective, invades the room. This apparatus is, therefore, probably destined to a decreasing use day by day. At present these stoves are the terror of architects, who are obliged to dissuade their clients from their use, for the chimney flues are by no means suitable for the proper working of such apparatus. The Academy of Medicine is also strongly against their use. Coming to the question of warm-air heating systems employed for the heating of entire dwellings, hotels, public buildings, and houses of many stories, we find that the simplest system is that employed since many years, and which, despite its inconveniences, is not easy to provide a substitute for. Its construction approaches that of the hot-air stoves, only the apparatus consists of a heating-chamber placed in the basement, from whence set out the various flues distributing the heat. These are of two kinds—that distributing the warm gases coming directly from the combustion, and that sending heated air in the necessary directions. Experience has shown that the heating chamber cannot send warm air to large distances; at 50ft. from the focus the loss in heat is already noticeable, and at a horizontal distance of 100ft. the air is almost cold. Despite the studies and researches of many well-known engineers—to whom, however, all homage should be made—this apparatus in nearly all its forms has the inconvenience of drying the air without affording a compensating moisture, and, besides, it conveys much dust and often deleterious gases.

The various systems of heating by hot water may be divided into two classes—that at low pressure, and that at high or average pressure. The first has the inconvenience of obliging the circulation of a large quantity of water through the apparatus, and the consequent necessity of providing flow-pipes of large diameters. The average temperature of the heating surfaces being only about 80° Centigrade, a considerable importance must be given them. In the systems of high or average pressure—generally preferred—the temperature of the water may be carried to 100°, or even above; the distributing pipes have, therefore, need of small diameters—a great advantage. The high-pressure system of Perkins brings the temperature of the water in the pipes to 300° and more, this high pressure occasioning possible accidents. In England and Germany this system has been much employed; but as yet, in France, the preference is for an average-pressure system composed of pipes of small diameter. Such a system is very convenient for dwelling-houses, permitting rational heating by means of a girdle of heat encircling the walls.

The system of heating by steam is obtaining great success in France for large public buildings and industrial buildings occupying large surfaces. It may be considered as one of the most rational means of heating, steam being the most powerful and supple vehicle for the conveyance of heat. With a system at low pressure, there is no fear of fire, dust, or noxious gases. As regards solidity, this system is nothing lacking.

On the question of ventilation, M. Gautier was of opinion that the simpler the system, the better the ventilation; that researches should be earnestly continued for the discovery of a system realising as nearly as possible natural ventilation. He mentioned an invention due to M. Emile Trelat, architect, this being the piercing of window-glass with a multitude of conical holes of very small size, the smaller base being at the exterior. This glazing had the advantages of being always clean, and allowing a mild ventilation without any draught. In the discussion following up this paper, M. Emile Trelat put forward his well-known theories on the matter. It was agreed that heating should be by radiation: the walls, the ceiling, the floor, and the furniture should radiate heat on the occupants of the room; the air itself should not be warmed, but should, on the contrary, be cold. A certain amount was said concerning defective chimney-flues and the injury done to people living on the upper floors through leakage from these flues. A resolution was passed that all newly-constructed chimney-flues should be constructed by the proper authorities, and tested as rain-pipes are tested to see that no leakage exists. This suggestion is really an exceedingly practical one.

M. Philippe, engineer, read a very lengthy paper on public baths at moderate prices, making a complete review of the various systems and apparatus for baths and bathing, giving plans of a model laundry, and comparing the systems of clothes-washing at London and at Paris, concluding greatly to the advantage of the former city. Plans and descriptions of public baths constructed by this engineer at Lille, Armentières, and Douai formed also a very interesting portion of the report.

M. E. Cacheux, engineer, administrator of the Society of Cheap Dwellings, read a paper on the evacuation of waste water in small towns and villages, giving the inconveniences and advantages of the systems of allowing waste water to flow from the houses into the streets; to flow into cesspools, or allowed to penetrate in the earth; to flow into rivers or running water; to be carried off by proper canalisations, and the dangers arising from the improper use or abuse of any of these systems.

M. Leon Benouville read a comprehensive paper on the necessity of a professional sanitary teaching, urging that the first endeavour of hygienists should be the inculcation of ideas of cleanliness and attention to sanitary matters amongst the general public and masses of people; the encouraging of cleanliness in schools, colleges, barracks, and public buildings by means of proper installations of every necessity and apparatus for cleansing purposes, giving no excuse for neglect in washing, bathing, and proper use of conveniences. He said that the State, towns, public companies, railway companies, &c., should give the good example in this way, citing the expenses made by the metropolitan of Berlin in the installation and maintenance of the public w.c.'s and urinals, expenses which were very high, but made so on purpose, in order to impress the public with the respect of cleanliness. He considered that public lectures on sanitation should be organised in a manner similar to those given under the auspices of the Sanitary Institute in England, that sanitary museums should be installed at Paris, and established on the basis of the Parkes Museum at London. At length they should pass resolutions relating to a petition to the Chamber requesting that a sanitary law for France should be adopted as soon as possible—a law giving all authority to mayors, prefects, and others to enforce a proper respect for the modern sanitary necessities; that men with a practical experience of sanitation be those most sought after for the general sanitary committees about to be organised; that proper classes and lectures on sanitation be created at the Ecole des Beaux Arts for architects, at the Ecole Centrale for engineers (or, rather, that the existing classes in the latter school be made more complete), at the School of Arts and Trades, and that associations for the popular teaching of sanitation be organised all over France, not forgetting the creation of museums of sanitation to be supported by the State.

A paper was read by M. Paul Pignant, engineer, on the necessity of the intervention of the public powers obliging the municipal authorities to control and enforce, if necessary, sanitary measures and laws, and that of the municipal authorities obliging private persons to take the measures necessary for the sanitation of private buildings and dwellings.

A very interesting report was made by M. M. Sijmons, engineer, of Rotterdam, on the results obtained by the Liernur system of sanitation applied at Amsterdam. He explained that this system obtains the evacuation of matter and house drains by means of an underground metallic canalisation, hermetically closed, ending at a central works outside the town, and employing suction as motive power. An immediate sterilisation of the waste matter was obtained by means of heating to a high temperature immediately on its arrival at the works, and a transformation into dry manure of a high agricultural value. In 1894 the central works of the Liernur system removed the drainage from 3,678 houses, containing 62,572 inhabitants, producing over 2½ million cubic feet of matter, necessitating the employment of 1,250 tons of coal. The works for converting the drainage dealt with a little over 2½ million cubic feet of matter, to which quantity nearly half a million cubic feet must be added, coming from the quarters not yet connected with the works, a total of about 3 million feet, giving 601·2 tons of sulphate of ammonia, and necessitating a total expense of 1,376 tons of coal. The sale of the produce left a profit of nearly £4,000. The working expenses of the Liernur system was in 1894 1s. 1½d. per inhabitant per year. By reason of this remarkable result, the Amsterdam town council has decided to give a greater extension to this system, and has voted the sum of £10,000 for the work of connecting the remaining 1,102 houses with 21,500 inhabitants with the works. M. Liernur claimed that his system yielded very handsome profits, also that their apparatus could evaporate and dry a little over four gallons by the consumption of 1lb. of coal. The reason of the large profit made was that the population only yielded 5¼ pints per person per day of sewage and house water; the drains and soil-pipes were thus scarcely ever flushed, and were therefore in a continual state of filthiness. Despite all arguments in favour of the Liernur system of drainage by suction, the Congress did not appear to show very much approval, and although the discussion was very animated, no vote or resolution was passed. The Congress seemed greatly in favour of the separate system becoming more and more employed in England. It was urged that with the separate system the quality and quantity of the sewage could be estimated to a near figure; again, the sewage was very easily treated by this system. The combined system of allowing rainfall to mix with the sewage added much difficulty to the work of converting. M. Masson was, however, of opinion that rain-water which had washed the streets was as foul as ordinary sewage, and should, for this reason, be treated as sewage.

A number of papers were read in the afternoons concerning various inventions and systems. The heating of schools, by M. d'Anthonay; the consequences in a health point of view of the dampness of the air in works and workshops, by M. de Betz; a method of purifying river water by means of currents of fresh air forced through the water, by M. Robert, engineer; several inventions for utilising house refuse; an ingenious mask for protecting workmen from injurious dust, invented by Dr. Detourbe; a system of rational closet-pans, suggested by Dr. Chatelin. The inventor maintained that the ordinary closet-seat was injurious, and created a predisposition to hernia, that the hips and spine should form an acute angle, and not a right angle; the closet-pans proposed by the doctor were fitted with a partial seat, which obliged the users to assume a position natural to the laws of anatomy. M. de Montricher explained a system of utilising badly-constructed large sewers by means of small drains placed within the large sewers; in case of very heavy rainfall only, the former would overflow into the latter.

This Congress has certainly been of much good in opening out the way to a better state of sanitation in France, in bringing the public attention to a realisation of the importance of sanitary measures, and in beginning the formation of societies, classes, and lectures on this all-important question.

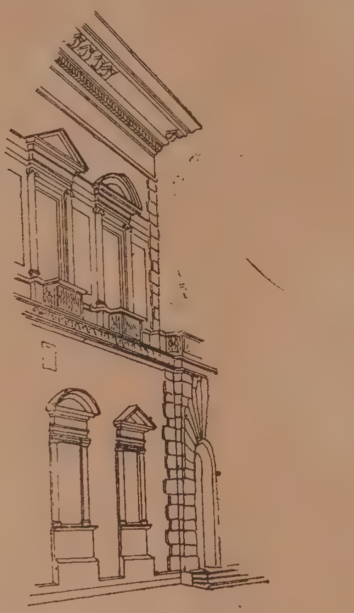
Arthur Vye-Parminter.

CLASSIC DETAILS AND THEIR APPLICATION.*

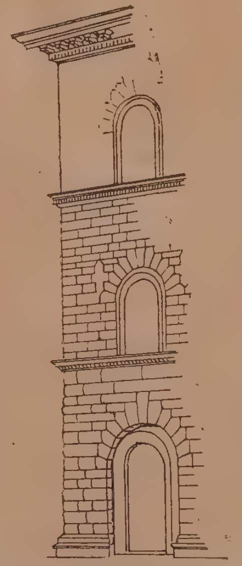
By G. A. T. Middleton.

VII.—ITALIAN RENAISSANCE: BUILDINGS TREATED AS ORDERS.

When Classic architecture was revived in Italy in the 15th century, known as the Italian Renaissance, the most noticeable feature was the manner in which it was at once adapted to the then modern requirements without the least of slavish copying. Nor, on the other hand, did it err in the opposite direction by the mere application of Classic details to buildings which were Gothic in form and principle. A somewhat similar thing had occurred before when Ptolemaic architecture arose in Egypt upon almost precisely the same lines as that of the Theban period of a thousand years before. Between the Roman and the Renaissance also there was a gap of a full thousand years; but this time it was not the same style which arose out of the ashes of the old, but a new style, fully adapted to present needs, based upon the principles of the old, and as instinct as that had been with all that pertains to architectural life—with vigour, with originality, and with high sense of the beautiful.



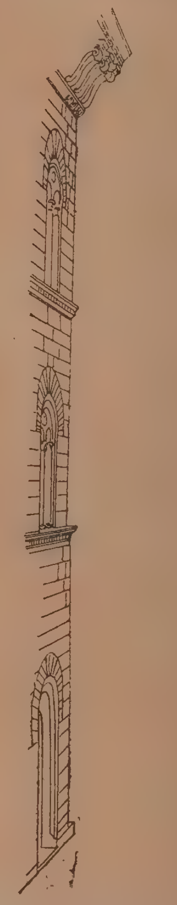
Pandolfini Palace, Florence, by Raffael. (From Schütz.)



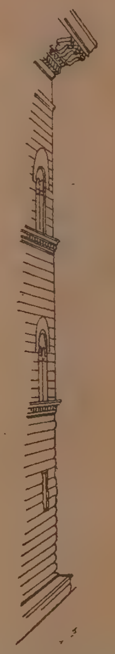
Gondi Palace, Florence, by Giuliano da San Gallo. (From Schütz.)

One of the first results of this was the treatment of buildings as a whole—as single units to which the parts were subordinate. This was especially exemplified in the palaces, which, from the circumstances of the times, were necessarily square masses of solid masonry, with but few and small openings within reach of any street mob which might attack them. Given these conditions, all that was necessary to convert them into architectural units was to crown them with cornices proportioned to their whole height, and this was accordingly done. No columns were used, but the buildings were left, of themselves forming complete orders without their aid.

The entablature, which thus became the chief feature of the design, varied considerably in its design. In the Riccardi Palace at Florence, the architrave and frieze are but slightly indicated, while a heavy cornice is carried by heavy consoles. In the Spannochi Palace at Siena, as also in the Gondi Palace at Florence, the architrave and frieze are missing entirely, while the consoles in the Spannochi Palace are deep, and in the Gondi Palace are widely projecting. Again, in the Strozzi Palace, at Florence, the architrave is missing; but there is a deep plain frieze, with enriched mouldings, then consoles, and then cornice over.



Spannocchi Palace, Siena, probably by Francesco de Giorgio. (From Schütz.)



Strozzi Palace, Florence, by Cronaca. (From Schütz.)

Speaking of the cornice only, which was the one absolutely necessary part of the entablature for the purpose of properly crowning the building, Gwilt gives the following table of proportional heights:—

Palace.	Proportion of cornice to whole height.
Spannochi, at Siena	·081
Picolomini, at Siena	·074
Pojana, at Pojano	·071
Strozzi, at Florence	·069
Pandolfini, at Florence	·069
Villa Monteccio	·069
Villa Caldoque	·069
Farnese, at Rome	·059
Gondi, at Florence	·057

As to the rest of the design, it was simple in the extreme. Great use was made of wall-surface, texture to which was obtained by rustication, the degree of rustication varying in most examples, the masonry being exceedingly bold when near the eye, and more and more finely faced the higher its position in the building. In a later school, however—the Roman, to which the Pandolfini Palace more properly belongs—the rustication is confined to angles and to the doorways; and in the Venetian school, to be referred to later, it is often absent altogether.

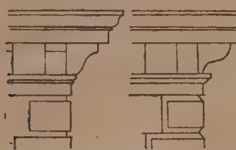
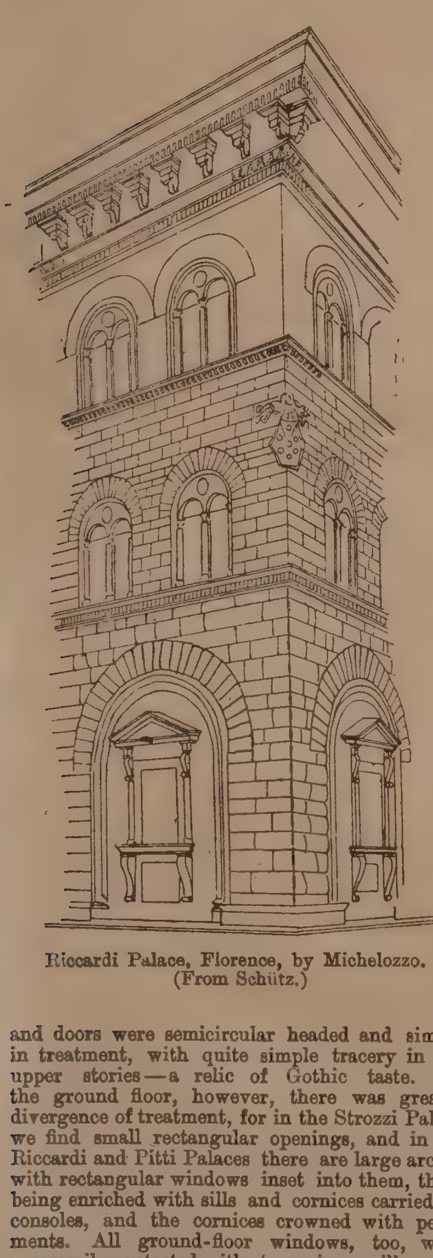
* All rights reserved.

The simplicity of the buildings was further enhanced by the regular arrangement of the openings, with doorway usually in the centre of each front, and by the subdivision of their height into stories by the introduction of horizontal strings or intermediate cornices carried right across the front. These were never obtrusive, having just this minor function to perform, generally consisting of a small cyma and corona, with simple consoles under. Still, their depth is nearly that of the main cornice, Gwilt stating $\frac{1}{15}$ of the height of the building, which is very little less than that of most of the main cornices, as given in the above table.



Two Intermediate Cornices, or Strings. (From Gwilt.)

In most of the Florentine Palaces the windows and doors were semicircular headed and simple in treatment, with quite simple tracery in the upper stories—a relic of Gothic taste. On the ground floor, however, there was greater divergence of treatment, for in the Strozzi Palace we find small rectangular openings, and in the Riccardi and Pitti Palaces there are large arches with rectangular windows inset into them, these being enriched with sills and cornices carried by consoles, and the cornices crowned with pediments. All ground-floor windows, too, were necessarily protected with strong iron grilles.



Riccardi Palace, Florence, by Michelozzo. (From Schütz.)

The Pandolfini Palace, it will be noticed, is an entire exception to these rules, for the intermediate string is enriched with the guilloche; the upper story is set back from the lower, and the windows are treated with orders. It was a method of treatment adopted largely in Rome, as witness the Farnese Palace, but rare in Florence.

LONDON ARCHITECTURE FROM AN AMERICAN ARCHITECT'S VIEW-POINT.

THE *Architectural Record* of New York for the current month contains an exhaustive article from the pen of Mr. Barr Ferree on "Architecture in London." The author freely criticises the buildings seen during a recent visit to the Metropolis, and his remarks are accompanied by nearly a score full-page illustrations from photographs of large residences and commercial buildings. He points out that English architecture "suffers from a unity of purpose among its architects, from the rapid changes in the popular taste of the day, from the importation of foreign styles for a few years only, to be cast aside for something in a later fashion. Even now its architects have scarcely found their level, are not yet wholly certain in what way to direct their talents, what style to use, what form to give that style. But though there is still uncertainty and mixture, there has been an incredible spread of correct architectural taste, of sound artistic feeling, of a striving after better things, of an effort to renew the historical continuity that was broken in the last century; and in this lies the strength of current English architecture. The land is filled with charming structures of previous times when people thought more about architecture and less of other things. These buildings are at the very doors of every living English architect, and in many cases those men who have achieved the greatest successes in recent architecture have been those who have most frequently sought inspiration at this inexhaustible source. This is something quite distinct from anything in any other country, unless it be Italy. The Renaissance in England is strongly tinged with English colour, and the British architect has a long unbroken past which, while it may not help him with models, will at least suggest possibilities of continuance and development."

Mr. Ferree asserts that, owing to the monotony of the older structures in the Metropolis, with the exception of the churches of Wren, and a few other buildings that might almost be counted on one's fingers, the most interesting of London structures are of very recent date. There is, he says, a dulness that permeates whole districts of the City, predominates in street after street of sickening negation, until almost anything is welcomed by way of change. One is not appalled, as in many cities, by the presence of architectural monstrosities; one is hypnotised by the endless reiteration of the same lack of architectural form, the most careless—or is it studied?—indifference to architectural values; the utter ignorance of architectural ideas, the complete mastery of commercialism that would do no more than provide the barest, ugliest shelter, and which, when applied to domestic work, is in the barest, ugliest, most intolerable of all forms, styles, and manners of building. Queen Anne's Mansions are typical examples of this style of building. If the older buildings of London are bad from the absence of architectural ideas, many of the newer ones are, he thinks, quite as intolerable from the attempts of would-be architects, speculative builders, and inexperienced persons to build and endow their city with wondrous things as bad in their positive characteristics as the older structures are in their negativeness.

Turning to the characteristics of the better class of work, the author says that picturesqueness is a strong note, perhaps the strongest note, in all new buildings. It is not always well done; but it is one of the chief ends at which London architects are striving. It may be seen in a somewhat too pronounced tendency to break up surfaces; it may be seen again in a somewhat too great fondness for detail, oft times too frequently repeated; and it may be seen again in the almost universal fashion of finishing a front with a gable. It is a survival or revival of the ancient picturesque quality of English work so commonly seen in all old buildings. This picturesque quality in London buildings is dependent on more than the modern revival. The small size of the buildings, even in valuable city sites, is another striking characteristic. This naturally heightens the picturesque tendency, since it is very much easier—and much more natural—to make a picturesque design on a small scale than on a large one. Owing to the British tenacity of custom, and the further fact that, so far as the writer could make out, unopposed enjoyment of privileges, one has not acquired by purchase, for a certain time, gives one perpetual rights thereto, there has scarcely been a change in heights. Perhaps, as striking an example as could be given of the tendency to the picturesque, is the charming office building designed by Mr. Pearson for Mr. William Waldrof Astor, just now finished, on the Thames Embankment. This is a veritable gem, small and delicate, and quite unlike an office building, so far as commercial exterior is concerned. The New Law Courts, the Imperial Institute, the Museum of Natural History, are all instances of large public buildings into whose design the element of picturesqueness has entered to a perceptible degree. In the Imperial Institute the architect has rather hurt his design than improved it by giving way to this tendency. In the Museum of Natural History there are more towers than there is the slightest need of, and the rich and abundant detail has not well stood exposure to the trying London climate. In the New Law Courts there is much detail and variation for the sake of picturesqueness alone; but take away this element, and the design, in each case, loses distinctly and disastrously, if, indeed, it does not become wholly commonplace.

With a fine determination to make the most of their opportunities, the builders of the older monotonous London houses built with a brick of dull hue, admirably suited, no doubt, to the atmosphere of London, but which enormously heightened the deadening effects of their structures. The architects of to-day bid fair to go as far in the opposite direction as their predecessors went in theirs. Brick and terracotta are the favourite materials, and very good and satisfactory results are frequently obtained with them. New brick of a brilliant red is much used, and some happy combinations are obtained with trimmings of a light buff stone, almost white when fresh. Not so successful is a sort of pink terracotta, an artificial mixture introduced by the manufacturers, and which seems to have "caught on" without any reason for the catching. It speedily becomes faded and dirty, and is not in the least suited to London. When used alone, the effect is bad enough; but, unfortunately, it is often employed in combination with red brick, not unpleasing when new, and, in fact, rather startling, but excessively depressing after the pink has lost its freshness. The ease with which terracotta adapts itself to ornamental and decorative purposes is a great snare to London architects. Centuries of experience do not seem to have impressed the average London architect with the knowledge that the climate of his beloved city is entirely unsuited for elaborate external detail. Sooner or later, detail in any material, in brick, in terracotta, or in stone, blackens and darkens until its value is almost gone, or until what was intended as an ornament becomes a positive eyesore; yet in the face of all but limitless examples many architects go calmly on adding piece after piece of detail to their buildings, and doing, with the utmost apparent glee, and sometimes in the best of good taste, just what they ought not to do. Besides the leading characteristics of current London architecture, already noted, are sundry devices and types of parts so frequently employed as to be fairly considered general, though in themselves scarcely distinctive. These include the constant employment of high-pitched roofs, since the Gothic revival, with gables and dormers, and in almost every sort of structure; in the elevation of the building, wherever possible, upon a low basement, usually partly underground, a system that obtains not only in dwelling-houses—though not now so frequently employed in the suburbs as formerly—but in the business and City buildings, where its use is much less logical; in a very general employment of broad, plain unornamented friezes between windows, bordered by string courses formed by the hoods of the lower windows and the sills of the upper; in the banding together of windows in vertical bays, though often crossed by horizontal lines, and in a land where the buildings are almost universally heated by open grates, the chimneys add a special note of their own to the design, and materially help in giving distinctive character. London architecture is not composed of the materials the architect has to use, of the devices at his command, of the method of design he follows, but in the manner in which he designs. Mr. Norman Shaw, for example, obtains quite unprecedented results by a thorough mastery of form, quite apart from ornamental detail—results, by the way, that many of his copiers and imitators have entirely failed in obtaining, even when they copied him most closely. Mr. Ernest George, whose style is wholly different from Mr. Shaw's, and who uses much more detail, resembles him in standing alone among his followers. It is the man that makes a building great or even interesting; the individuality he puts upon it, the feeling he breathes into it. There is a good deal of building in London in which this may be noted, buildings which lift current English architecture well up from the indifferent and the mediocre, and place it, so far as domestic work is concerned, in the very front rank of modern architecture. If American architects would know the best that is now being done in their art—they cannot afford longer to ignore the claims of modern English architecture. It is not always great, it is not always satisfactory, it is frequently full of faults, and personal affectation ofttimes spoils a design otherwise harmonious and beautiful; but in its best examples it is always interesting, and often rises to the very highest type of modern architecture. With scarce an exception, the modern Renaissance buildings of London which have been designed under French influences are, Mr. Ferree declares, totally uninteresting. Such, for example, are the Bankruptcy Courts, the latest addition to the General Post Office, and Sir George Gilbert Scott's Public Offices, Whitehall. The two former structures are the results of officialism in architecture, which appears to no greater advantage in London than in America. Of the successful Renaissance structures in London the first place is unquestionably held by the City of London Schools on the Victoria Embankment. In striking contrast with the elaborateness of this design at one end of the Embankment, is the New Scotland Yard at the further extremity. This is a severe and stately design by Mr. Norman Shaw, in which the effect is obtained wholly by careful proportions, strong walls, and simple windows. The severity of the architecture, which includes no ornament whatever, save the rings of the turret bases and the heavy entrance porch—barring the not altogether happy gable ornaments—is perfectly in keeping with the purposes of the edifice. Yet, plain as it is, it bears the impress of the work of a consummate architect, who knew exactly what to do in the right place. The author is a perfervid admirer of Sir Charles Barry's Houses of Parliament—"an edifice so grandly thought out, so superbly planned, so satisfactory in its masses, its forms, its detail, that one can scarce realise that it was the work of a single man in the present century. Fortunately it has had no copiers, nor is it a building one would see copied." In critcising Street's Law Courts, he remarks that the almost unparalleled disputes between the architect and his committees, during the construction, were of so painful and vacillating a nature as to be responsible for many of the errors. It is its misfortune to be placed where it cannot be seen. It is especially unfortunate that the main façade should face the winding Strand, since from no single spot can the whole of it be seen. Possibly, Street himself was fully alive to this circumstance when he broke his main front up into almost as many parts as it could be broken into, separated them by turrets that are monotonous in their frequent reiteration, and designed what is really a series of fronts that open up one after the other, as the building is approached from the direction of Charing Cross. Even though necessitated by the site, the building suffers from this treatment, and is lacking in the unity of exterior that may naturally be demanded in so long and important a front. Even as it is, the best use has not been made of it. The turrets are wearying in number, and not altogether pleasing in design. The arcade carried across much of the lower part of the façade, partly as a screen, partly as a dividing line from the street, and partly, no doubt, as a device to unite the whole in one idea, quite fails of its purpose, and scarcely amounts to more than a hindrance to light and air. The entrance to the main hall, originally intended to be parallel to the Strand, instead of at right angles to it, as it now is, is further wanting in the monumental treatment that should have been given to it. But the whole structure is, the writer thinks, a marvellous monument to the industry, the genius, and the ability of the architect. The Imperial Institute, at South Kensington, is the newest large public building in London. Built from the designs of Mr. T. E. Colcutt, it is a notable addition to the large buildings of London. The building was intended to typify and represent the unity and majesty of the British Empire, and both popularly and professionally is regarded in London as completely failing to accomplish the specific purpose for which it was erected. Possibly the error lay in the style, which is a rich English Renaissance. A more stately style of architecture was, perhaps, needed here; but the architect had frittered away many of his opportunities by the elaborateness of his ornament and the breaking up of his surfaces. The design is distinctly ornate, save the tower, which is bold and fine, and is crowned with a dome, unfortunately not of stone, surmounted by a lantern. It is quite justifiable to find fault with the immense quantity of detail applied to this structure. Very good in itself, there is quite too much of it for the London climate, and in a very few years its ornamental value will have entirely departed. Of the other new public and semi-public buildings in London there is little to be said, save that none of them approaches in interest those that have been named. The new Admiralty Offices are of commonplace design, treated with pavilions at the ends and in the centre, and with engaged columns of buff stone against a brilliant red brick, a combination that in its unfinished state is more noteworthy for its colour than for its design. The new Record Office in Chancery-lane follows very closely the design of the older structure, and is, in consequence, a somewhat notable instance of good taste on the part of the architect. Mr. Waterhouse's building for the City of London Guilds and Technical Institute, at South Kensington, avoids the too rich detail with which his near-by Natural History Museum is ornamented, and in the severity of its forms not unnaturally suggests the mechanical arts taught within it. In the additions to the National Gallery, a more severely Classical design than that of any other public building in London, the architect had the extremely difficult task of having to piece a new part on to an old structure of rather tame if refined design, and which he performed as well as the conditions of the case permitted. In business buildings London offers examples of every sort, the good and the bad, the old and the new, with a preponderance of both the bad and the old. Yet with so many horrible examples of what not to do the modern architect often fails in his commercial designs. Usually he errs in putting on as much ornament and detail as he can, as though architecture began and ended with this silly process. One of the best of the new buildings is Mr. John Belcher's Institute of Chartered Accountants. Yet it is hidden in a maze of narrow streets where the average passer-by would never stop to look for it, where even those seeking it may miss it, and where its value both to itself and as an ornament to the City is almost totally lost. Internally the building is not so happy as without. The detail, while well worked up, is sometimes heavy, and the proportions unpleasing; but taken as a whole this is one of the most interesting of the newest of London buildings. The new building of the Metropolitan Life Assurance Society in Moorgate-street, by Mr. Aston Webb, is an eminently successful and interesting design. It is entirely harmonious; it is not four designs heaped one on the other, but a single design divided by four lines; the distinction is very great, and the success of the building depends on the way in which this has been done. London contains many other buildings, some good, some bad, with emphasised horizontal lines, but it is seldom that one discerns an element of discord. The principle of unity is well understood, and this is one of the important lessons that current English architecture can teach American architects.

Mr. Ferree adds: Interesting as many London commercial buildings are, they scarcely approach in interest the domestic buildings. These are of amazing richness and variety of design, and here the English architects appear, as a whole, at their best. Of the many English architects engaged in actual practice none has produced more notable domestic buildings than Mr. Norman Shaw. That such a man should have his imitators is without question, and quite as natural is it that his copiers should, most of them, entirely fail in approaching him in the quality and beauty of his designs. The houses of Mr. Shaw are notable for the obtaining of architectural effects with the simplest materials. Ornament is the least important servant he calls to his assistance, and not unfrequently he dispenses with it altogether. His thorough mastery of design, and his keen artistic feeling enable him to produce extraordinarily interesting results of the very highest type of fine domestic building, where a less sensitively artistic man would have only failure and dissatisfaction. The newer parts of London contain many interesting groups of houses. Mr. Ernest George has impressed his personality upon one notable district, and has contributed to the adornment of many others, while other architects, in their own special way, have added their quota to the interesting new dwellings of London. Mr. Ernest George's work is wholly distinct from that of Mr. Shaw, depending as it does more upon detail and a general richness of design for its effect. If there is sometimes a greater variation of surfaces than seems always necessary, if there is an enrichment of parts and a wealth of ornament, it is at least satisfactory to feel that it is always good and very often intensely and charmingly picturesque. If the traveller in London will compare the older parts of the city with the newer, he will not long remain in doubt as to the value of the work English architects are now doing. Take, for example, the streets in the neighbourhood of Russell-square, or even the older streets in the neighbourhood of Hyde Park, and compare them with the groups of houses in Harrington-gardens, in Collingham-gardens, with Mr. Shaw's houses in Queen's-gate or on the Chelsea Embankment with the newly-built section in and around Cadogan-square, with Kensington Court-gardens, or with the artist homes in Melbury-road, and he will realise, as it is otherwise impossible to realise, just what the English architects of the present day are doing for their Metropolis. The success achieved by the leaders in the new movement has provoked a host of copiers. It is this inferior work that predominates in the new localities, or, rather, which surrounds the kernel of good buildings which marks the beginnings of many of the new districts. Whether in time to come the progress of the inferior architecture and its indefinite multiplication will cause a revulsion towards a new series of models the author is not prepared to say.

In conclusion, Mr. Ferree devotes some space to the consideration of modern London churches. Mr. Pearson clearly takes the lead in this work, though the churches of Street, of Bodley, of the younger Gilbert Scott, and of Sedding should not be overlooked. "The churches erected by this quintette of architects are, taken as a whole, real churches, characterised by a true churchly feeling, a feeling that, in many instances, permeates the whole design and gives it a life of its own quite apart from the form used. Mr. Pearson has been especially happy in giving this effect to his churches, and while his exteriors are not always as expressive nor as inspiring as his interiors, it is impossible not to feel their originality and true churchly nature. Most of these new churches are in brick, stone sometimes not even appearing in the detail, save in the window tracery. Yet though brick is the most difficult material with which to obtain monumental effect, there is no poverty in the design, either external or internal. The lesson these churches teach is unmistakable. The architect is master of his work. Mr. Pearson, for example, never copies Mediæval forms, never reproduces Mediæval churches, but builds a modern 19th-century church with the materials handed down from the Middle Ages. It is not the least remarkable feature in current English work that an architect in active, busy practice can produce buildings of such a character. It shows that English architecture—yes, English Mediæval architecture—contains elements of vitality with which as yet we on this side of the Atlantic are scarcely acquainted."

COUNTY LUNATIC ASYLUMS.—XXIV.

By George H. Bibby, F.R.I.B.A.

SANITARY BUILDINGS.

In no part of an asylum is the evil of overcrowding (occasioned by the constantly-increasing numbers of the insane without corresponding extensions of accommodation) more likely to be detrimental to the health and well-being of the patients than in the buildings for sanitary purposes, whether these be attached to the main buildings, as described in my last paper, or in connection with the workshops and airing-courts for patients.

The necessity for providing ample means of inspection of the occupants of these sanitary buildings would be better understood by an architect, and he would be better able to appreciate the great difficulties connected with the subject, if he would (instead of merely passing through the pleasant and tastefully-decorated day-rooms occupied by quiet and orderly patients, the great majority of whom are frequently industriously employed, or amusing themselves, and sometimes interesting to converse with), inspect the wards occupied by the disorderly and refractory patients, say, on a *rainy day*, when eighty or ninety patients are confined to their rooms. He would then have an opportunity of witnessing the evil effects of crowding a number of excitable patients into rooms of insufficient area (frequently without proper outlook or surroundings), and would sometimes find such a scene of anger, turmoil, foul language, and coarse laughter as would sadden and horrify him; that such scenes yet occur may be seen by reference to the "Forty-second Report of the Inspectors of Lunatics for Ireland" (p. 94), where the Governors of the Belfast Asylum had their attention directed to the fact that their patients were "*crowded promiscuously together without order or regularity into a human mass of mental degradation and confusion*," and where they (the Governors) are reminded that the accommodation must be greatly increased, both in the wards and administrative buildings.

If to all the above-named disadvantages there be added the occasional occurrence of outbreaks of diarrhœa and sickness amongst the patients, the asylum architect cannot fail to perceive that the plans to be prepared for asylum sanitary annexes have to be considered subject to many complications and under, perhaps, conflicting conditions.

Perhaps nowhere do the sanitary arrangements appear to be more defective than in some of the Irish asylums, and in the wards for idiots and lunatics in some of the Irish workhouses (as appears by the report I have above referred to) matters appear to be worse than in any part of England or Scotland; but in many cases the governors of the district asylums in Ireland are said to be fully aware of the necessity of meeting the requirements of their respective districts, and in a large number of instances have already sanctioned the necessary expenditure for alterations and additions; so we may hope, within a reasonable time, that the accommodation will be rendered in some degree better adapted to meet the immediate wants of the insane poor.

The working patients in asylums may be divided into two classes: those employed upon field or garden works and occupations requiring physical strength in workrooms, &c., and those only capable of employment upon tailoring or light occupations.

Separate water-closet or earth-closet, urinal, and lavatory accommodation is advisable for these classes, and should be in proximity to the workshops and workyards, and so arranged that one class shall not be brought into contact with the other—i.e., the stronger with the weaker.

The water-closets and urinals to be provided in connection with the workshop buildings should never be placed in direct communication with any of the apartments, whether occupied by the workers or used for storage purposes; but some similar arrangement to that provided for the wards should be adopted, with similar means of inspection of the patients, and separate closets for the use of attendants and work-master (provided with lock and key), and if slightly detached from the workshops, covered ways should be provided. Some of the patients have not sufficient intelligence either to avoid a shower of rain or to perceive the necessity of a change of clothing after getting wet through, and an attendant might not notice, until too late, the condition of his charges; hence the necessity of a covering roof from the workrooms to the closets.

The water-closets for the sick and infirm or bed-ridden patients, and in the asylum fever wards, may usually correspond with those provided in the best modern hospitals, but with due attention to the precautions already referred to with regard to cases which may be suicidal, and the means of observation of the patients. The annexes in which they should be placed may also contain a space for a movable bath, and the ordinary adjuncts and utensils required for *hospital* use.

Near to the entrances to the various wards, from the airing-courts and grounds, an earth or water-closet is sometimes conveniently provided, the door should open outwards, as for all other closets intended for patients' use, and be without bolt or other fastenings, that the attendants be not excluded should it be necessary to exercise restraint or control of a patient. In suicidal cases, I believe, it is usual to issue to the attendant, when taking charge of a dangerous case, a form upon a slip of parchment, which the attendant is required to sign, and which, after giving details of the patient's condition, states:—"*I am not to leave him for any purpose without giving him in charge to another attendant, to whom I am, at the same time, to give this caution I am to accompany him to the closet, to search his bed-clothes before he goes to bed, to remove and search his clothes, and see him dress in the morning*," &c. Bearing this precaution in recollection, it will not be difficult for the asylum architect to realise that the arrangement and position of sanitary buildings for the use of patients require more than ordinary consideration.

The forms of water-closet pans most in favour in asylums are the wash-out and wash-down, both of which have the manifest advantage of being without valves or moving parts, and therefore have no mechanism liable to become disarranged or broken by the patients.

Instead of the chain usually provided for the purpose of setting the water-waste preventer, an iron rod or wire should be provided within a casing of wood or metal, as the chain might be used for suicidal purposes.

The urinals should not have any pans or receptacles above the level of the floor. There should be an automatic flush every few minutes, and there should be laid on a supply pipe from the nearest hot-water cistern, so that the urinals may be easily scalded out occasionally.

As urinal pans should not be adopted, and as a gutter in the floor is all that is necessary, it would be advisable to provide a gutter receptacle for the urinal-tablet disinfectors, which are now in general use; or otherwise, these would be liable to removal by the patients, many of whom meddle with or steal the most trifling objects. These "Sanitas" urinal tablets are very useful, especially during hot and close weather, and they may also be used in the cisterns which supply the water-closets, and for this purpose should be placed in specially designed cases so that the pipes may not be clogged with the tablets.

The sanitary annexe may also contain a cupboard or locker for the storage of disinfectants, &c., so that the nurses and attendants may not have to leave their charges to go to the general stores for what they may require. Disinfectants are largely employed in asylums, for their use in water-closets, urinals, ward sculleries, &c., tends to keep the atmosphere pure. The objection which some people have to the strong odour which most of the disinfectants possess, prevents them from using these valuable agents, so useful where large numbers of dirty insane patients are accumulated.

The bath for patients of dirty habits, which may sometimes be advantageously placed within the sanitary annex, should have some disinfecting arrangement. A bath is made with an internal flushing rim which is supplied with water that has passed through a disinfecting box. This apparatus is manufactured by Messrs. Adams and Co., of Westminster, and is an antiseptic apparatus for hospital use, which also appears to be very suitable for the dirtier classes of asylum patients.

With regard to the sanitary building generally, it must be remembered that fevers and other fatal diseases are generated more or less by atmospheric impurities, and that the more patients of dirty habits are crowded together, and have the light and air shut out from them through defectively planned asylums, the more do they become liable to these and other maladies. Effectually comprehensive measures are yet necessary in many districts. There can be no doubt that the habitual respiration of the air of ill-ventilated and gloomy alleys in large towns is a powerful means of augmenting the hereditary disposition to scrofula, and even of inducing such a disposition *de novo*. Physiologists show that those distressing maladies, *goître* and *crétinism*, are due to noxious local influences, chiefly to a stagnant atmosphere; and, as is well known, the complaints are most prevalent in deep valleys, in which the circulation of air is very intermittent or languid, and the fact remains that improved structural arrangements neutralise, if they do not destroy, the causes of mischief, and contribute to the permanence of health. Even without seeking for special cases, we may rest assured that impure air, among other ill effects, causes deafness, and in other ways injures the individual, leaving him a victim to various ills. Architects and builders of former times appear to have been most astonishingly ignorant of the physiological fact that man carries an arrangement of lungs beneath his ribs fitted only to inspire a pure atmosphere. In asylums especially, attempts for education and improvement of patients, if concurrently *without sanitation*, must be inefficient and unsatisfactory, for it is not easy to elevate minds familiarised with filth and squalor, and there is an essential dependence between physical and moral purity.

The instructions and suggestions issued by the Commissioners in Lunacy to architects and others concerned with asylum works do not particularise the kinds of apparatus and fittings to be provided in the sanitary buildings, and indeed give but little information beyond pointing out the necessity for efficient ventilation, and the desirability of using tiles, glazed bricks, or cement for the floors and walls of the water-closets and lavatories, &c.

The selection of a suitable apparatus is a matter of some difficulty. There are, I believe, about 25 well-known firms in this country who manufacture sanitary ware and apparatus of various descriptions, and of these there are several who make wash-out, wash-down, and trough closets that are suitable for asylum patients. For instance, large numbers of the "Sydney Syphonic Cistern and English-made Closets," manufactured by John Jones, of Chelsea, have been used in lunatic asylums. Amongst other firms who have supplied suitable water-closets and apparatus are Messrs. W. H. Bodin and Co, of Wednesbury; Messrs. T. and C. Clark and Co., of Wolverhampton; Mr. T. W. Twyford, of Hanley, Staffordshire; Messrs. A. Emanuel and Sons, Limited, of London; Messrs. Joseph Cliff and Sons; Messrs. J. Taylor and Sons, Limited, of London; The Water Carriage Engineering Co., Limited, of Sheffield; Messrs. Charles Winn and Co., of Birmingham; and Messrs. Adams and Co., of Westminster, and from these may be selected fittings to meet the varying preferences of committees, medical superintendents, and others connected with asylums; but some authorities are of opinion that a perfectly suitable apparatus has not yet been contrived satisfactorily meeting all the requirements of the case as regards the most demented and dirtier classes of patients.

Whatever mechanism be used for the flushing of the closets, it is necessary that it shall be suitable for the unintelligent and violent classes of patients; it should not depend for its action upon a varying strength or length of pull, and if a pull be used at all it should act instantly. An objection has, however, been raised to automatic flushing arrangements set in motion by the movement of a door or seat, or foot pressure, not only upon the ground that these are liable to get out of order, but also for the reason that the patients should be encouraged in the smallest matters to use their reason so far as their mental condition will permit. But there are certain of the worst class of patients who are confined in single rooms; these are the most disgusting, to the attendants, of all, and are left alone during the night to do as they will, and are taken out in the morning in a condition of filth that is beyond all powers of description. In public asylums for boroughs and counties, and in the lunatics wards of workhouses such cases and arrangements may be expected; but in private asylums, where a larger proportion of attendants and nurses are provided, the patients would probably receive more attention.

During the past twenty-five years, or more, I have been engaged upon the plans of as many lunatic asylums, and from the first have noticed that the architect must often find that the medical superintendent of the asylum frequently influences the schemes for the structures to a considerable extent, and, indeed, somewhat encroaches upon the special province of the architect.

A medical man, connected with an asylum, recently wrote as follows (entirely ignoring architects and other scientific men):—"It is curious that there are only three professions. All over the civilised world, parsons, lawyers, and doctors are regarded as members of the three professions, and the rest of the world is placed in a heterogeneous mass and called unprofessional. However, when the word is used loosely, we sometimes speak of actors, and so forth, being professionals; but this only shows to what base uses words may come, and everyone still recognises the three professions, the earthly trinity of intellect."

If these words, and the spirit in which they are evidently written are to remain unchallenged, architects may incur the disadvantages to be expected by those who permit their occupation to be interfered with or discredited by untrained persons engaged in other pursuits. It is, therefore, as necessary that architects should possess at least an equally intelligent knowledge, for instance, of asylum doctors and patients and their requirements, that asylum doctors have (or may consider they have) of the duties of architects and the building requirements of sanitary buildings.

(*To be continued.*)

TRANSPORT OF BRIDGE GIRDERS BUILT UP TO THEIR SITE.

IT has always been a recognised maxim in all workshops, and by all classes of artisans, craftsmen, and workmen, from the principal downwards, that the more of the work belonging to any particular job that can be done in the shop the better. Not only is it done in a superior and more satisfactory manner than in the field, or outside the shops, but it is done a great deal cheaper and a great deal quicker. There is no description of metallic construction to which this remark applies more forcibly than to bridge and roof girders and trusses, the majority of which are frequently erected far from where they are partially built up, and often in very exposed situations. The greater the number of pieces in any particular example, the greater will be the number of joints, and the larger the number of bolts and rivets required to form the connections. Riveting and bolting up separate pieces of iron and steelwork outside in inclement weather in winter-time, in even our comparatively mild climate, is unavoidably a troublesome, a tedious, and unpleasant undertaking. The difference in the style of the work, between that executed in the shops and in the field, is sometimes so marked that an experienced professional eye has little or no difficulty in detecting generally what portion has been put together in one locality, and what has been built up in the other. If these disadvantages are so marked at home, it is not difficult to imagine how gravely they become accentuated in foreign and semi-savage countries. It is no wonder, therefore, that engineers and architects are desirous of despatching their girders and trusses for bridges and roofs, to be erected abroad, in as few component parts as possible. Cast-iron girders all in one piece, when of small span, unquestionably offer better facilities for erection in distant and uncivilised lands than their wrought-iron rivals. Against this advantage must be set the greater liability of the cast-iron girders to injury, and even to actual fracture, during transit. It is essential that a cast-iron girder should arrive at its destination in a condition as sound and as perfect as when it left the premises of the manufacturer. This condition is frequently a somewhat hazardous one to accomplish, when we take into account the chances of injury which may occur to it during its transport. Again, the difficulty attending the safe carriage of castings increases notably with their size and weight, which in their turn depend upon, *cæteris paribus*, the span of the bridge or roof.

So far as the transport of large and heavy girders, trusses, and frames, whether of cast or wrought iron, is regarded solely as between port and port, there is little or nothing to be feared, unless in very exceptionally stormy weather. The ships which carry merchandise and goods of every description to the remotest parts of the world are now sufficiently large to house examples of iron and steelwork endowed with dimensions and proportions which some years ago would have been deemed excessive. It is when the outgoing vessel arrives at the end of the voyage that the risk and trouble begin. In the majority of instances there is not the shadow of a port or harbour of any description, or the slightest sign of wharf, jetty, or landing-place to disembark heavy and valuable machinery and other weighty and costly commodities. As a highly favourable case, let us suppose that there is fair landing accommodation, and that it is possible, either by the use of the shore cranes or the steam winches belonging to the vessel, to hoist out of the hold and safely deposit on *terra firma* the heavy ironwork sent out. If it were required for the port itself or the immediate vicinity, the job might be considered pretty well at an end; but in nine cases out of ten it is wanted many miles up in the interior of the country, especially when it is intended for mining purposes. We can call to mind an incident connected with the transport of mining machinery in the Malayan Archipelago. Some heavy and expensive quartz-crushing gearing was in the act of being hoisted into a native boat, when by some neglect or other the hoisting tackle slipped, the hoisting chain ran out, and the quartz-crushing machinery stove in the bottom of the boat, and went clean through it, into the muddy bed of the river, where, there is not the slightest doubt, it is now deeply buried. A delay of nearly a year in the ultimate prosecution of the mining enterprise, which, contrary to what so often occurs, was a very successful venture, was the result of this unfortunate *contretemps*.

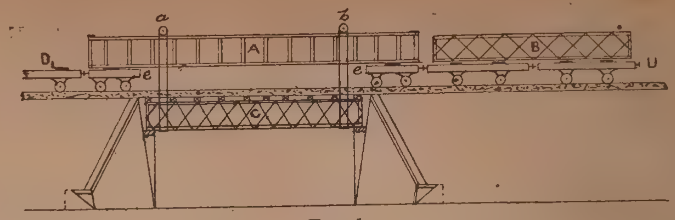

Fig. 1.

Where circumstances will permit, whether at home or abroad, it is, from what has already been stated, a decided advantage to rivet up a bridge girder complete and transport it bodily, all standing, to its future resting-place. There are several methods of accomplishing this desirable operation, and one which is novel and possesses particular merit is represented in Figs. 1 and 2. It will be seen, as we proceed with the description, that the principle is of general application, although, for the sake of a clear illustration, the particular example shown in the figures will be adhered to. A pair of plate girders, A, are firmly secured to a pair of short waggons or trollies, *e e*, one at each end, which gives to the whole arrangement a strong resemblance to one of the large bogie swing saloon carriages on our large railways. The space between them is necessarily open, save for a few cross-planks here and there, which can be removed and replaced, as permitted by the exigencies of the hoisting and lowering appliances. Coupled to the shorter trollies are two ordinary trucks, D and D_1. Three or more may be used, according to the length of the girder B, although there is a practical limit to that dimension. In the example before us it is proposed to remove the old girder C, Fig. 1, and replace it by a new one, B, Fig. 1, which has been hauled to the site upon the platforms of the waggons D. The pulleys *a b*, carrying the chains and other tackle, are free to run along the upper boom of the plate girders, which, in the position represented in Fig. 1, are brought right over the old girder C, and the tackling chains made fast underneath it. The sleepers and ballast can then be removed, and the preparations concluded for hoisting it up out of the way. When slung up between the pair of lifting girders, a part of it can, by means of the running pulleys, be slewed on to the waggons D_1, and finally adjusted and secured. By reversing the direction of the running tackle, the new girder B can be hauled in between the girder A, and gradually lowered down upon the bed-plates as shown in Fig. 2. Should it happen that the old or new girder exceeded in depth the lifting girders A, the difficulty of hoisting the one and lowering the other can be readily obviated by placing a rail on the upper boom of the former. The new girder B, having been installed in the seat of the old one C, the cross-beams and planking can be relaid, and the road metal or permanent way renewed, accordingly as the bridge is a road or a railway structure.

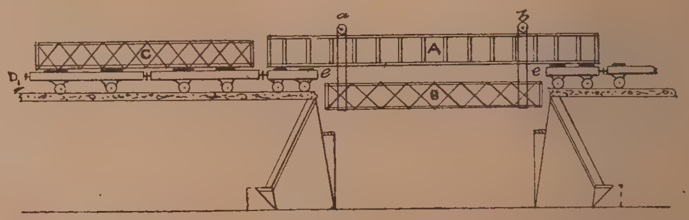

Fig. 2.

The span and weight of the new girder will evidently determine the limit to which this portable method of depositing it *in situ* can be extended. Owing to the ever-increasing loads to which both railway and road bridges are, and will in future be, subjected, it may be concluded that the new girder will always exceed in weight its disused predecessor. When the girder B in Fig. 2 is being lowered into its place, one-half of its weight is carried upon each of the small trollies *e e*, and if R and R_1 represent the two reactions, we have the well-known equation—

$$R = R_1.$$

But in hauling the girder B into the position to admit of its being lowered away, the whole weight may for a short period of time rest upon only one of the trollies *e e*, so that, in this case, if W be the weight of the girder B, the reaction is—

$$R = W.$$

At the present time when a large number of railways, both at home and abroad, are replacing their old bridges by new ones, it is clear that by giving a maximum span to the lifting girders, A, the arrangement would be available for all structures of a less lineal dimension. Considerable use of the method illustrated in Figs. 1 and 2 has been made on some of the Austrian lines of railway, but the maximum span to which it has been applied has not exceeded 40ft. There would be no difficulty in extending in this country the span to 60ft., which is a very usual one for both railway and road bridges, and, moreover, has been largely employed in India. Indeed, in the early days of railways in our empire of Hindostan, when large rivers had to be crossed by bridges consisting of numerous spans, the problem of the most economical span to adopt, so as to determine likewise the most economical number of piers, was very seriously and carefully considered. The result was that a span of 60ft. was adopted, which was found, local circumstances and other conditions permitting, to afford the most satisfactory solution of the whole question.

◆

The new schools, Tonyrefail, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates, the same being supplied by Messrs. E. H. Shorland and Brother, of Manchester.

Mr. James Saunders Randell, of Bath, has been elected a director of the Bath Stone Firms, Limited, in the place of the late Mr. James Stone. Mr. Randell was the senior partner of Randell and Saunders, the well-known stone firm, of Corsham. He has a practical knowledge of the trade and a wide experience which cannot but be of much service to the company.

Messrs. Maxwell and Tuke, architects, surveyors, &c., of 41, Corporation-street, Manchester, have now prepared plans, and are proceeding with the erection of an extensive cattle-market, abattoirs, and agricultural hall, for Mr. Thomas Johnson, Prescott-street, Wigan.

Messrs. Anniston, contractors, of Alabama, U.S.A., have secured the contract for the supply of iron water pipes, to be shipped to Tokio, *viâ* Liverpool. The English, German, and Belgian contractors were underbid.

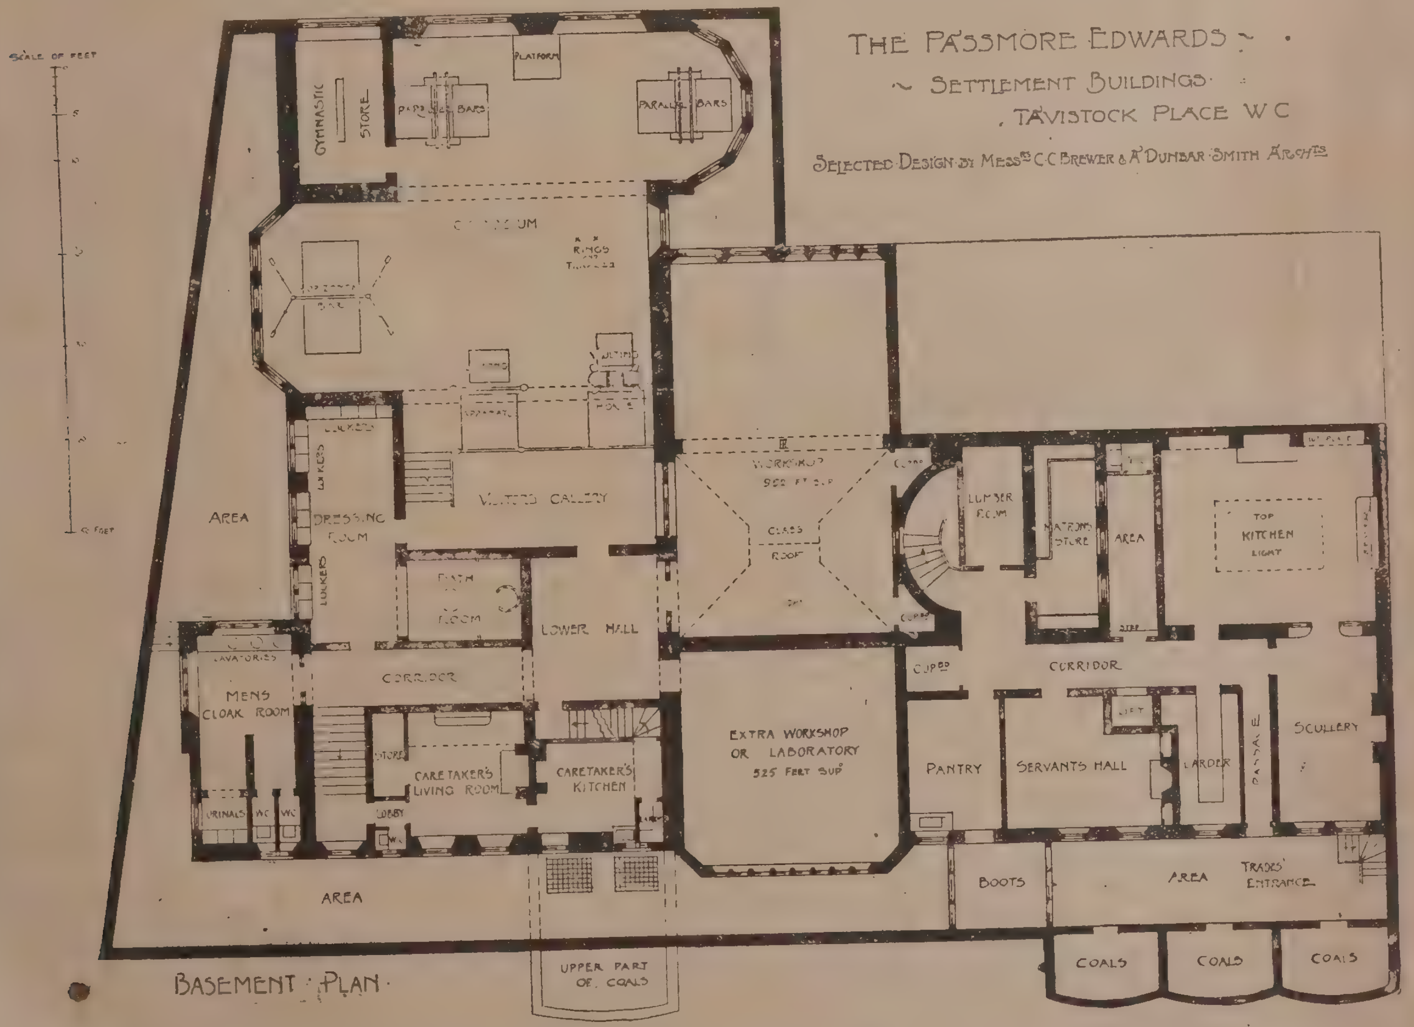
THE PASSMORE EDWARDS SETTLEMENT.—STANWAY HALL: ARCHITECTURAL ASSOCIATION EXCURSION SKETCHES IN GLOUCESTERSHIRE.—HOME AT CHALFONT (MR. EDWARDS'S) —GLOUCESTER CATHEDRAL.

Our Illustrations.

◆

THE PASSMORE EDWARDS SETTLEMENT BUILDINGS, TAVISTOCK PLACE.

We illustrate the selected design chosen by Mr. R. Norman Shaw, R.A. The rooms are in all cases of the maximum size mentioned and arranged in accordance with the competition instructions. The hall has been placed in Little Coram-street, and the residence in Tavistock-place, as being more appropriate for living-rooms, owing to the greater width of the street, with the added advantage that the rooms at the back look out upon the gardens. The hall and residence have been kept quite distinct, with separate entrances, but connected by a corridor. The hall, seating 456 persons, has been placed on the first floor, the staircases constructed in accordance with the London County Council regulations, and provided with ample retiring-rooms. Care has been taken to make the library as attractive a room as possible; it overlooks the gardens on two sides, and is planned with a large bay-window. The reading-room also overlooks the gardens, and is placed in a quiet position. The billiard-room is placed between the hall and residence. The four class-rooms are grouped together. A large gymnasium has been placed in the basement, with a gallery for spectators at one end. The large workshop is top-lighted, and an extra workshop or laboratory has been provided. The caretaker's rooms open off the stairs to the basement close to the front door. The residence practically consists of two separate blocks, united by the staircase and bath-room accommodation, which are thus kept away from the rooms, and are well ventilated, while the unsightliness of external soil-pipes is avoided. All the sitting-rooms have an aspect overlooking the gardens, except the dining and billiard rooms, which have a north light. The entrance is placed near the centre of the Tavistock-place front. The drawing-room is opposite the entrance, and is placed on the garden level, with a lobby leading out to the garden. A detail drawing is shown of this room. The dining-room, with servery, is on the first floor, the warden's residence is placed over the drawing-room, and a private way is provided for him into the hall. The common room is placed among the residents' rooms, which occupy the two upper floors. Fixed lavatories have not been shown in the residents' rooms; they would add enormously to the cost and seem scarcely necessary, as bath-rooms and lavatories are provided on each floor. Store-cupboards are provided over the lobbies. The matron's room opens from the entrance vestibule, and commands the tradesmen's entrance, and the servants' bedrooms are so arranged that the only access to them is past both the matron's rooms. The question of cost has been kept constantly in view, and the simplest possible treatment has been adopted both internally and externally, as will be seen by referring to the detail drawings, although it is thought that the appearance of the building will not suffer on that account. After going carefully into the question with a quantity surveyor, it is believed that the cost of the building will only slightly exceed £12,000. Messrs. C. C. Brewer and A. Dunbar Smith are the architects.



A.A. EXCURSION TO GLOUCESTERSHIRE.

A descriptive account of the places to be visited during this excursion will be found, together with further illustrations and a map of the district, on p. 180, *ante*.

HOME FOR EPILEPTICS, CHALFONT ST. PETER'S, BUCKS.

This home for men has been erected at Chalfont St. Peter's, aided materially by Mr. J. Passmore Edwards, who laid the foundation-stone November 14th, 1894. It was to have been opened by the Duke of Devonshire on Wednesday last, the 7th inst.; but owing to the fact that almost at the last moment the Duke was summoned to Osborne by the Queen, the opening ceremony of the building has unavoidably been postponed till the autumn. This building is the first permanent home built by the Society for the Employment of Epileptics on their estate in Buckinghamshire. The accommodation is provided for 18 colonists, in addition to an isolated room with two beds. The finishing of the building, both inside and out, is of the plainest description, it having been necessary to exercise the utmost economy in the matter of expenditure. The work has been carried out in a most efficient manner by Mr. Darlington, of Amersham, under the supervision of the architects, Messrs. Young and Hall.

◆

The foundation-stone of the esplanade extension at Lynton will be formally laid on Thursday next, the 15th inst.

Mr. W. B. Richmond, R.A., who has been travelling in Italy, has lost this week his fourth son, John Sebastian, who died in an hotel at Paris on Monday, aged 19 years.

OBITUARY.

By the death of Mr. Samuel Loxton, which took place at his residence at Cannock on Monday morning, after a week's suffering from rheumatic fever, one of the oldest and best-known architects and surveyors in South Staffordshire is taken away. For many years he and his brother practised at Wednesbury—their birthplace; but some twenty-five years ago, when the partnership was dissolved, he removed to Cannock, and carried on business there and at Walsall. Among the public edifices in that immediate district which were built from his designs are the Town Hall, Wednesbury; Wesley Chapel, Wednesbury; the Temperance Hall, Walsall; the Trinity Wesleyan Chapel, Walsall; the School Board Offices, Walsall; and some of the schools belonging to that board, in addition to many other important buildings farther afield. He was also in great request as a witness in the law-courts on questions relating to building and surveying.

The sudden death is announced of Mr. Arthur Ebden Johnson, F.R.I.B.A., of Market-buildings, Melbourne, the president of the Royal Victorian Institute of Architects. Mr. Johnson read a paper at a recent meeting of his institute held at Melbourne, and appeared in excellent spirits. On the following morning, when proceeding to his business from his residence in Windsor, and about to enter a tram-car in Chapel-street, Prahran, he fell down dead. Mr. Johnson won the Soane Medallion of the R.I.B.A. as far back as 1843, and was very many years connected with the Public Works Department of Victoria, as architect. On retiring from the Colonial service he entered into partnership with Mr. A. L. Smith, forming the well-known firm of architects of Smith and Johnson. Among the numerous public buildings in Melbourne in the construction of which he was professionally interested, may be mentioned the Law Courts, Union Bank, Colonial Mutual Insurance Buildings, and Bank of Victoria. Eleven years ago he joined the R.I.B.A. as a Fellow. Mr. A. E. Johnson stood at the head of his profession as an architect, and as a citizen was highly esteemed for his courteous manner and kindness of thought and action.

Mr. Edward Swansborough, architect, died at his residence, 68, Richmond-road, Barnsbury, N., on Monday last, aged 72 years. He was formerly in practice at 6, Great James-street, Bedford-row, and was at one time an Associate of the Royal Institute of British Architects, but had retired from the profession.

M. Ancelot, the well-known architect, died in Paris on Monday in his 66th year. He designed the new frontage of Pau Castle, the theatre at Compiègne, and the new buildings of the Arts et Metiers at Paris. Since 1873 he had been a professor at the school of fine arts.

◆

Mr. W. O. Dalgleish, of Errol Park, Perthshire, has just presented to the Dundee Museum a fine specimen of an ancient Caledonian canoe, recently discovered in the River Tay, opposite Errol. Formed of a single oak-tree, and probably hollowed out by means of fire, the canoe measures 29ft. in length and 4ft. wide at the stern; it narrows to about 2ft. wide at the bow. The stern only has been a separate piece, and has been inserted into a groove 3½in. wide. One side of the canoe is almost complete, while the other has sustained considerable damage. At the bow there is a hollow, as if intended for the attachment of a figure-head.

The members of the Kent Archæological Society held their 38th annual meeting on Tuesday and Wednesday in last week, the headquarters being Cranbrook. In that village the parish church was visited, and a paper on its history read by the Rev. J. Cave-Browne. Glastonbury House and Goudhurst Church were also visited on the first day, the proceedings closing with a dinner at the George Hotel, Cranbrook, and an evening meeting. On the second day, Beneden and Hawkhurst Churches were seen, under the guidance of Mr. J. Oldrid Scott, and also Bodiam Castle, where Mr. W. H. St. John Hope read a paper.

It is the intention of Messrs. T. B. and W. Cockayne, of Sheffield, to construct an arcade from Angel-street towards Meeting House-lane in that town, and the work will be proceeded with at once, under the superintendence of Messrs. Flockton and Gibbs, architects. The scheme is to convert Watson-walk into an arcade 12ft. wide and 43 yards long, commencing from Angel-street, at which end it will be widened, and shops will be constructed on either side of the arcade.

Building Intelligence.

Bootle.—A start has been made with the erection of the new Presbyterian Church of England, Peel-road, Bootle. The church is designed to accommodate 600 worshippers on the ground floor, having no galleries, and will be built of grey and red brick artistically treated. It will have a large single-span roof, divided into bays with transepts. There will also be vestries and rooms for Sunday-school purposes. An organ gallery will be provided in the west transept. The present church will be used as a school with a covered connection with the new church. The work is in the hands of Messrs. Raffle and Campbell, of Liverpool, contractors, and will be completed in about twelve months. Messrs. Woolfall and Eccles, Castle-street, Liverpool, are the architects.

Ipswich.—The Eastern Counties Dairy Institute, Limited, which has been incorporated since Old Michaelmas Day, 1888, has recently made an important forward step in transferring its business from Rise Hall, Akenham, to Gippeswyk Hall, Ipswich. At the new premises a dairy has been built which was formally opened on Tuesday. Messrs. Eade and Johns, of Ipswich, are the architects, and the work of building was intrusted to Messrs. Grimwood, of Sudbury and Ipswich. The new building, the side of which abuts upon the Ancaster-road and the front on the main drive to Gippeswyk Hall, is a two-story edifice of red brick, covered with a roof of Broseley plain tiles. There are three gables in front, finished with tile-hanging above the windows, and also with framed barge-boards. The main rooms, which are paved with York stone, and have dadoes of glazed tiles, are the cheese-room, 20ft. square, lecture-room, 40ft. by 20ft., and the churning room. The sale-room has marble fittings, and is paved with tiles.

Pontefract.—The Right Rev. Lord Bishop of Beverley laid the foundation-stone of the new national schools at Pontefract on Friday last. The new building is to be erected from the plans of Mr. J. H. Greaves, architect, of Leeds and Pontefract, which were accepted in competition, and will be a fac-simile of a school recently erected at Featherstone (three miles distant) from the designs of the same architect, and will give accommodation for 350 girls. The large school-room is divided into three classrooms by means of glazed movable partitions, each room having separate exits to the cloakrooms. There are also to be two classrooms, each for 60, and adjoining the central room and end classrooms. Provision is made for adequate heating of rooms and lavatories by means of slow-combustion open fires. The new school will occupy a position adjoining the boys' and infants' schools, and will cost, exclusive of site, £1,500.

Wandsworth.—The first section of the new Church of St. Thomas of Canterbury at West Hill, Wandsworth, was opened on Sunday week. The church as designed, and when completed, will consist of nave, aisles and transepts, chancel with two side chapels, sacristies, and tower with baptistery. The general dimensions of the completed church will be as follows:—Nave, 92ft. by 30ft.; chancel, 25ft. 4½in. by 30ft.; aisles, 15ft. wide; transepts, 22ft. 10in. deep (the one built) and 25ft. deep; Lady-chapel, 24ft. 7½in. by 15ft.; side chapel, 17ft. 7½in. by 11ft. 3in. The nave is 30ft. to the under-side of the tie-beams, and 42ft. to the top of barrel. The chancel will be in three bays, vaulted in wood. The aisles will have flat wooden panelled ceilings, and large windows. The baptistery under the tower is to be sunk three steps, and will be vaulted in brick with bands of stone. The total seating capacity of the church is for 700 persons. The materials are red bricks and Bath stone for the exterior. The roofs are to be of pitch pine covered with Westmoreland black slates, and the flooring of nave is in wood blocks—pitch pine under the seats, and oak in the passages.

York.—Sir G. W. Kekewich, K.C.B., Secretary to the Education Department, on Saturday formally opened two new board schools at York, which have been erected at a cost of over £30,000. The new schools have been erected in Fishergate and in Lowther-street, and both are built on the central-hall system, which is being generally adopted by the School Boards throughout the country. The Fishergate school is built on the site known as Mollett's field, and will provide accommodation for 1,250 children. It is built in the style of the Georgian period, of red common bricks, the total cost, including the site, being about £14,000, or an average of £11 4s. per scholar. The Park-grove school has been built on a site between Lowther-street and Park-grove, and will accommodate 1,486 children. The buildings are in the Georgian style of architecture, and are of plain, substantial materials. The cost of school and site has been £17,000, equivalent to £11 8s. per head. Both schools have been built from the designs and under the supervision of Mr. Brierley, of Messrs. Demaine and Brierley, architects, York. The brickwork, masonry, and joiner-work of the Fishergate school was executed by Mr. T. P. Barry, York, and of the Groves school by Messrs. Thos. Arnold and Sons, Doncaster.

CHIPS.

A large new clock has been fixed in the church of Norton-sub-Hamden, Somersetshire, which chimes the Westminster quarters and strikes the hours. It has been made generally to the designs of Lord Grimthorpe by Messrs. John Smith and Sons, Midland Clock Works, Derby, who also made the clocks of the neighbouring church-towers of Shepton Beauchamp and Kingsbury.

On Saturday morning the workshops of Messrs. S. J. Waring and Sons, Limited, cabinet-makers, situate in St. Anne-street, Liverpool, were destroyed by fire. The damage is estimated at over £20,000.

At the Liverpool Assizes on Monday, Mr. Justice Wills, sitting without a jury, awarded a widow living in Southport £120 as damages, with costs, against Messrs. Blanchard and Son, contractors, of the same town, for injuries sustained by plaintiff in falling into an unprotected hole 6in. deep made in a street by plaintiffs to receive a scaffold-pole outside a shop. The defence was that men in the employ of the corporation were flagging the street in question, and had not come within 7ft. of the hole when the accident occurred.

The roof of the nave of Winchester Cathedral is reported by the architect to the Dean and Chapter, Mr. John B. Colson, of Winchester, to be in a very unsatisfactory state. Several extensive fissures exist in the vaulting, owing to the shifting of timber tie-beams, so that their weight falls upon it. The urgently necessary work is estimated to cost £6,000.

After a long discussion, the Wallesey district council agreed to promote a Bill to enable the council to extend the promenade from Marine-terrace, Liscard, to the ferry at New Brighton, this scheme having previously been approved by the board.

Good progress is being made with the works of the Upper Stour Valley Main Sewerage Board, who have just completed the purchase of land for a sewage farm at Whittington. Messrs. C. B. Martin and W. J. Fiddian, of Birmingham, are the engineers.

The very interesting old pre-Reformation clergy or priest's house at Alfriston, near Eastbourne, is to be preserved to the nation, the Ecclesiastical Commissioners having consented to transfer the building for a nominal sum to the National Trust for Places of Historic Interest or Natural Beauty.

The foundation-stones of a new Wesleyan chapel, which is being erected in the Himley-road, Gornal Wood, were laid on Monday. The building is being erected on the site of the old chapel, which had become dilapidated owing to mining operations and other causes. The new building is being erected by Mr. J. E. Buxton, from designs prepared by Mr. J. Hall Gibbons, Birmingham, at an estimated cost of £1,640.

A public memorial is to be placed in the Fraser Chapel of Manchester Cathedral to Mrs. Fraser, widow of the second bishop. It will take the form of a stained-glass window and a tablet.

Major General Scott, the water examiner of the Metropolis, is instituting inquiries on behalf of the Local Government Board into the causes of the scarcity of water in the East-end. Mr. A. R. Binnie, the engineer to the County Council, and Mr. W. B. Bryan, the Water Company's engineer, are assisting Major Scott in the preparation of his report to the Local Government Board.

A striking picture of Wells Cathedral has been painted by Mr. Walter Severn for Bishop Kennion, who intends to present it to the public gallery at Adelaide as a memorial of his Australian episcopate.

The city council of Coventry adopted, at their last meeting, a scheme prepared by Mr. James Mansergh, C.E., for the disposal of the sewage by the extension of the present works, and the acquisition of additional land for the filtration of the effluent in the Avon Valley. Mr. Mansergh was instructed to prepare the necessary detailed plans for the carrying out of this scheme.

COMPETITIONS.

Chester.—The Chester Baths Committee have received and approved the award of Mr. Frank Baggaley, 66, Conduit-street, Regent's-street, placing the design with the motto "Plan" first in order of merit. The author of the successful scheme is Mr. Harold T. Burgess, 33, Palliser-road, West Kensington. There were about 170 inquiries for block-plan and conditions, but only 27 designs were sent in response to the town council's invitation.

Durham County Council Buildings.—Mr. J. Vickers Edwards, county architect, Wakefield, acted as referee in this competition, and not Mr. MacVicar Anderson, as inadvertently stated in a paragraph printed by us last week.

Eisteddfod Pavilion. — At the National Eisteddfod, held at Llanelly last week, the awards of prizes were announced on Friday. An important item on the list was the competition for the best design for a movable permanent pavilion suited for the requirements of the National Eisteddfod, with complete specifications, estimates, and full details, for which the National Eisteddfod Association offered a prize of £25. The object of the association is to secure a permanent building for the future national gatherings in North and South Wales, and thus avoid the annual outlay of large sums of money to the towns in which the Eisteddfod is held. The adjudicators were Messrs. Charles Evans Vaughan, F.R.I.B.A., London; W. E. Davies, and Rhys Davies. The result of the adjudicators' examination was to the effect that only one set of plans came to hand. The design proved to be a facsimile of the pavilion erected at Pontypridd in 1894, but of lesser area. The internal arrangements were nearly alike to those at Wrexham, 1888, and Swansea, 1891, but precisely similar to those at Brecon, 1889. The design showed a considerable improvement upon all of them in respect of the offices and committee rooms, and the addition of a museum and art department attached to and connected with the main building was a feature not hitherto followed in temporary pavilions. The adjudicators agreed that a pavilion built in accordance with the design would be convenient and satisfactory. The author had omitted to couple with this plan the complete specifications. If these were supplied they recommended that the prize be awarded to him.

Ipswich.—The guardians of the Ipswich union have adopted the recommendation of the assessor, Mr. Charles Barry, F.S.A., and have awarded the first premium in the competition for a new workhouse to the plans prepared by Mr. W. Lister Newcombe, of Newcastle-on-Tyne, and Messrs. Salter and Adams, of London, acting conjointly. The outlay will be about £20,000.

◆

The Sunday-school buildings on the north side of Crown-street Congregational Chapel, Ipswich, are being extended. The new buildings, of which the memorial-stone was laid by Mr. D. Ford Goddard, M.P., on July 30, are of white brick, with Monk's Park Bath stone dressings. They include a men's classroom, 40ft. by 17ft.; infants' schoolroom, 15ft. by 17ft.; two other classrooms, and kitchens. Mr. Frank Brown, of Ipswich, is the architect, and Messrs. T. Parkington and Son, of the same town, are the builders.

At the last meeting of the district council for Lynton a communication was read from Mr. Pickell, Cardiff, stating that some seven years ago he had taken soundings for the construction of a pier at Lynmouth. He now made a proposal to obtain a Provisional Order for constructing a pier 200ft. long from the end of the new Esplanade and 25ft. in width. Its cost would be about £25,000. It was resolved that the clerk be instructed to write Mr. Pickell, saying that the council was favourably disposed to consider the matter, and that, after a consultation with the ratepayers, he should hear something more on the subject.

The opening of the new chapel which the Sisters of Mercy have built on to their convent in Blandford-square took place on the Feast of St. Anne. The chapel, which was designed by Mr. Edward Goldie, is 109ft. long by 26ft. broad and 47ft. high. The shape is a simple oblong, without side chapels. A feature of the interior decoration are six tall niches in the side-walls, three on either side, with carved pediments and canopies, which are ultimately to contain statues of saints. A high altar, in carved white stone, the reredos adorned with figures in high relief of angels and of St. Peter and St. Edward, has been erected. The eastern façade of the chapel, overlooking Blandford-square, is all of stone, and is adorned by a white stone statue of Our Lady with the Holy Child.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—B. Farnley.—Amateur.—J. W. and Co.—E. S.—Cestus.—B. F. and Co.—J. T. (Dudley).

E. W. Meredith, Torquay. (We published the selected plan for the Fulham Palace-road board schools, by Messrs. Arnold Mitchell and A. M. Butler, in our issue of July 19, 1894, side by side with the plan by Mr. T. J. Bailey, F.S.A., the architect to the London School Board, for the schools of the same capacity (1,200 places) built in Lillie-road, Chelsea. Comparison of the two schemes will be interesting and helpful.)

Correspondence.

DURHAM COUNTY BUILDINGS COMPETITION.

To the Editor of the Building News.

Sir,—Your report of the proceedings of the Durham County Council, in your last issue, is somewhat inaccurate and misleading. We trust you will therefore afford us space to make one or two corrections. In the first place, Mr. MacVicar Anderson was not the assessor, but Mr. Vickers Edwards, architect to the County Council for the West Riding of Yorkshire. In the second, you state that the assessor awarded the first place to us, and the second to Messrs. Barnes and Coates, of Sunderland.

We wish to point out that the assessor's award has not been made public, although it has been asked for by one of the competitors, and that we have the best of reasons for believing that the latter owe their position entirely to the action of the Council, of which, we are informed, the father of one is an alderman.

Your report then seems to imply that we have been passed over, through our not having strictly complied with the conditions.

These have in every way been most carefully adhered to by us, and in spite of the fact that we were only allowed a fortnight in which to obtain a *bonâ fide* tender, we *did* submit one, by Messrs. Holloway Bros., of Battersea, which was in amount even less than our own. We had to submit this on or before the 18th of May last, yet the meeting of the Council was not till the 24th of July. We can now read between the lines. Not being able to trip us in this way, it is now evident that the Council (of which Mr. Samuel Storey is the chairman) felt bound to award us the first premium, and then threw us aside in favour of their friends.

It is certainly time that strong measures should be taken to prevent, if possible, architects from receiving such unfair treatment at the hands of public bodies.—We are, &c.,

Cooksey and Cox.

19, Craven-street, Charing Cross, W.C., Aug. 6.

Intercommunication.

QUESTIONS.

[11391.]—**Workmen's Houses.**—I wish to build some workmen's houses, two rooms each, with scullery behind; room's size 15ft. square. How should I get at the cost? Are there any books that will give me the information independently of my local workpeople? It is near Glasgow, and the material should be brick or concrete.—A. A.

[11392.]—**Polisher.**—Will any kind reader tell me the best way to French polish new mahogany shop-front sashes, &c., to bear against weather, or any other polish used as substitute?—Killarney.

[11393.]—**Ice Chambers.**—Will any reader kindly direct me where I may get information *in re* above? If any book is published, will be pleased to have title. Or if any one could furnish sketch and description, a favour will be conferred on—Colonial.

[11394.]—**Cement Facing.**—Will some practical reader inform me what is the best material with which to face the panels (on brickwork) in the old timbered style for gables, &c., so as to dry a white or cream colour? I have already put on a ground of Portland cement, and am thinking of facing with Keene's. Will this stand weather for a length of time? Full particulars will oblige—J. C.

CHIPS.

The Bishop of Norwich, on Thursday in last week, preached at the reopening of the church at Burnham Market, Norfolk, the birthplace of Nelson, which has just been restored at a cost of £7,000. The reopening was on the 97th anniversary of the victory of the Nile.

Considerable additions are about to be made to the Dominican House at Hawkesyard, Armitage, near Rugeley, which was given last year to the Fathers, together with a large estate, by a generous benefactress. A new church and priory are to be built, under the supervision of Mr. E. Goldie, architect. The existing mansion is to be converted into a college for aspirants to the Dominican Order.

The remains of the old market cross of Congleton were recently presented to the corporation of that borough by Mrs. Johnson. It has now been decided to re-erect the stones on a vacant site in the High-street.

The special committee appointed by the Manchester City Council have at length come to a decision as to the most suitable sites for the two drinking fountains presented to the city by the late Mr. Jardine. They recommend that the larger of the two fountains should be placed in Queen's Park, and the smaller one at the corner of Butler-street, Oldham-road. These recommendations have been adopted.

The will of Mr. Charles Bartholomew, C.E., formerly of Broxholme, Doncaster, and late of Castle-hill House, Ealing, who died on January 12, was proved on July 18, the value of the personal estate amounting to £290,955.

It was announced at Wednesday's meeting of the Manchester City Council that the portrait by Sir J. E. Millais of the late Bishop Fraser has been bequeathed by Mrs. Fraser to the Corporation of Manchester.

On Friday, in the presence of pupils and friends of the Bristol Cathedral School, the completion of the restoration of the beautiful Early English doorway, leading to the school, which has been undertaken at the expense of past and present pupils of the establishment as a mark of esteem to the head master, was celebrated. The archway has been restored under the superintendence of Mr. J. L. Pearson, R.A.

On Saturday, a new public park for Falkirk was opened. The park formed part of the grounds of Thornbank, in the northern part of the burgh. The ground was purchased by the town council, at a cost of £5,500. It is about 16¼ acres in extent, and has been named the Victoria Park.

The adjourned inquest on the body of David Jones, the fifth man who was suffocated at the East Ham Sewage Works on July 1, was concluded on Wednesday. The jury returned a verdict that death was due to suffocation by sewage gas, adding the expression of their opinion that the East Ham district council was guilty of great negligence in not providing proper appliances to prevent such an occurrence.

Legal.

DISTRESS FOR RENT.

THE judgment of the Court of Appeal confirming the ruling of a Divisional Court in the recent case of "Palmer v. Bramley" (*Times*, 20th July) is one of much importance as an authority upon the principle involved. The Courts have formerly held up the right of a landlord to distrain as something so sacred that he did not abandon it, even if he took a security from his tenant for the rent in arrear. Thus it is laid down in the older books that, even though a landlord takes his tenant's bill of exchange for the rent due, he is not bound to wait until that has been dishonoured; but can exercise his summary remedy of distraining meanwhile, and notwithstanding. Seeing that by the ordinary law, if a creditor takes his debtor's bill for a debt owing, he certainly cannot sue for the money while that bill is running; it seems somewhat harsh to allow a landlord to have it both ways; yet, in the case above noted, where a tenant had given his acceptance, and the landlord distrained before it was due, the County Court judge held that he was entitled to do so according to the earlier authorities.

Fortunately, the Court of Appeal, following the Divisional Court, has reversed their judgment. They held that the taking of a bill of exchange by a landlord is some evidence that he agreed to suspend his right of distraint while the bill was running, and, therefore, that the jury should have been asked to decide whether this was so or not. The case was thus practically sent back to the County Court to be tried again; but in a general way any jury and any man of business would at once say that if a landlord takes his tenant's bill of exchange for rent owing, he does thereby agree to wait until that bill is due, and not to distrain meanwhile. One object of the bill being given is obviously that time should be granted for payment, while another may be that the landlord should have a security upon which he could, by discounting it, acquire the money if it is wanted. To allow a landlord to take and hold his tenant's acceptance, and at the same time to use his summary remedy by distraint, is certainly to give him an unfair privilege that is denied to all other creditors, and it is satisfactory that this should be no longer legal.

Fred. Wetherfield, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

Enquirer.—Estimate.—Tender.—I do not see how the contractor could make any claim against anyone for the time and trouble taken by him in preparing his estimate and tender—which no one was bound to accept, and which, although in fact the lowest, was not accepted—unless there was some agreement as to such a payment.

◆

The medals and decorations of Lord Nelson, which were recently purchased by the Treasury from Lord Bridport, on behalf of the nation, have been handed over to the Royal Hospital, Greenwich, and will shortly be placed with the other mementoes of Lord Nelson in the Painted Hall of the hospital for exhibition. Mr. J. A. Mullens has also presented to Greenwich Hospital the gold sword-hilt presented to Lord Nelson by the captains who served under him in the battle of the Nile and the gold box in which the Freedom of the City of London was presented to him.

Discontent is said to prevail in the Straits Settlements, because of the manner in which the present governor, Sir Charles Mitchell, interferes with the action of the municipal councils of these towns. The case at issue is that in agreeing to advertise in England and elsewhere for a civil engineer to take charge of important works, the municipal council fixed a dollar salary equal to about £900 a year, being the sum they had paid to the deceased engineer. The governor refused to sanction a salary beyond £775 a year; and the members of the municipal body are now forced to advertise the appointment at a salary they have declared to be insufficient.

The dissolution of partnership is announced of the firms of T. E. Watkins and A. M. Alexander, under the style of A. O. Watkins, Son, and Alexander, Newport, architects, engineers, and surveyors. Dissolution of partnership is also notified of the firm of C. H. Payne and F. C. Martin, architects and surveyors, Chesterton, under the style of Payne and Martin.

LEGAL INTELLIGENCE.

Committee's Promises are Binding.—Graham and Sons v. Huddersfield Corporation.—This case, which was heard on July 29 and 30 before Mr. Justice Mathew and a special jury, was brought to recover the sum of £999 11s. 10d., the balance alleged by the plaintiffs to be due to them by the Huddersfield Corporation on a contract entered into in June, 1891, for the construction of a brick culvert. The defendants contended that only the sum of £66 was due. The cost of the work, the plaintiffs stated, was much greater than had been originally anticipated. Mr. Waddy, for the defence, urged that by the terms of the contract the plaintiffs were bound to make the sewer, whether they had to deal with soil or shale or rock. The contract had been made upon the footing that the plaintiffs were not going to have to deal with any rock. That was where they made their blunder, and why their estimate was about £1,000 less than that of anybody else, because the other people had taken into consideration that there was rock. The committee were strongly against giving plaintiffs anything, and they absolutely denied having promised to make the defendants an allowance.—Mr. Atkinson, for the plaintiffs, said the work was stopped for fifteen weeks because of the refusal of the plaintiffs to go on until they had written instructions from the committee that they would pay. Instead of an open trench, the plaintiffs were called upon to make 240 yards of tunnel. Mr. Graham went before the committee, and his statement was that he got a promise from the committee to be paid whatever Mr. Dugdale, the borough surveyor, thought proper. Counsel also pointed out that the committee had made an offer to pay £250 entirely without prejudice. That minute was not ratified by the town council, but was sent back to the health committee for reconsideration. His Lordship, in summing up to the jury, referred to the minutes of the health committee's proceedings, which, he said, showed that the plaintiffs were to go on with their work, and that on its completion they should renew their application. It was perfectly open to the committee to say to the plaintiffs that if they did not wish to abide by their contract, other contractors would be engaged to carry out the work. If that had been so, however, there would have been some record of it; but, so far from that being the case, there was a distinct record showing that the plaintiffs might renew their application on the completion of the work. The jury found that the defendants had promised to make an allowance, and that the promise had been broken, and they gave a verdict for the plaintiffs for £800. Mr. Manisty made application for a stay of execution on the ground that the promise made was not binding on the corporation. His Lordship: Not for a day.

Building Act Appeal.—Crow, Appellant, v. Redhouse, Respondent.—The Court of Appeal heard, on July 31, an appeal from the judgement of the Divisional Court upon a case stated by a metropolitan police magistrate on an appeal by Samuel Redhouse under section 150 of the London Building Act, 1894 (57 and 58 Vict. c. ccxiii.), against a decision by Arthur Crow, the district surveyor for the Whitechapel and Spitalfields district. Section 150 provides that where it appears from the building notice served on the district surveyor under this Act that it is proposed to erect any building which may be in contravention of this Act, the district surveyor shall serve upon the builder or building owner a notice of objection, and it gives an appeal to a magistrate from this notice. It appeared that Redhouse proposed to rebuild a six-story warehouse, No. 3, Church-street, which, in consequence of a fire, was taken down as dangerous in November, 1894, for more than one-half of its cubical extent, so that the proposed building would be a "new building" as defined by section 5, subsection 6, of the London Building Act, 1894, which defines the expression "new building" as "any building which has been taken down for more than one-half of its cubical extent and re-erected, or commenced to be re-erected, wholly or partially, on the same site after the commencement of this Act." A notice of objection was served by the district surveyor on Redhouse. The matters in the notice were, however, remedied with the exception of the objections made to the use without thickening of a wall, forming the west boundary of the site as the party-wall between the reinstated warehouse and the adjoining warehouse, No. 1, Church-street, the said wall not being in conformity with the provisions of the Act as to new party-walls. Before the fire the party-wall had been the party-wall between Nos. 1 and 3. So far as the party-wall concerned No. 1, which had not been seriously injured by the fire, it had been reinstated in the course of the reinstatement of No. 1. These reinstatements had not amounted to the erection of a "new building" at No. 1. Redhouse appealed to the magistrate, on the ground that he was not compelled by law to make the party-wall conform to the provisions of the Act of 1894. The extent to which the party-wall had been burnt and taken down in consequence of the fire amounted only to one-third of its superficial area. The remainder was safe. The party-wall had been erected in conformity with the previous Building Acts, but was not of the thickness required by the Act of 1894. Redhouse contended that as the party-wall had not been taken down, burnt, or destroyed to the extent of one-half thereof, by virtue of section 208 of the Act of 1894 the proposed use by him of the party-wall was not in contravention of the Act. Section 208 enacts that "unless in any case the Council otherwise allow, where a party-wall or external wall not in conformity with this Act has been taken down, burnt, or destroyed to the extent of one-half thereof (measured in superficial feet), every remaining portion of the old wall not in conformity with this Act shall either be made to conform therewith or be taken down before the rebuilding thereof." The surveyor, Crow, contended that the proposed re-erection being a "new building" within section 5, subsection 6, of the Act of 1894, the party-wall should be so erected as to comply with the provisions of the Act, and that there was no exemption enacted or implied in section 208. The magistrate held that Redhouse's contention was correct, and that he could not be compelled to take down, rebuild, or thicken the party-wall. In the Divisional Court Mr. Justice Wills held that the magistrate's decision was right, Mr. Justice Wright dissenting. The magistrate's decision was accordingly affirmed. The district surveyor appealed. The Court dismissed the appeal. The Master of the Rolls said that they could not find any section in the Act which enabled the surveyor to deal with this wall. Section 10 of the former Act (the Metropolitan Building Act, 1855) seemed to have been dropped out of the present Act, and the Court could not read it in. As to section 5, that section merely defined the expressions used in the Act, and it was clear that it was not an enacting clause. Lords Justices Kay and A. L. Smith concurred.

Leith Builders' Claim against the Caledonian Railway Company.—Evidence was begun on Monday in the Windsor Hotel, Edinburgh, in an arbitration between Messrs. Bryson and M'Intosh, builders, Thorntree-street, Leith, and the Caledonian Railway Company. A portion of the Company's new Leith line runs diagonally through a square of tenements (bounded by Easter-road, Gordon, Thorntree, and Halmyre-streets) belonging to Bryson and M'Intosh. Seven of the blocks are to be acquired by the Railway Company, and the purpose of the arbitration is to fix their value and the amount of depreciation suffered by the adjoining blocks owing to the proximity of the railway. Bryson and M'Intosh claim £24,000. Mr. Comrie Thomson, advocate, is oversman, and Mr. John Blair, W.S., and Mr. A. W. Belfrage, C.E., act as arbiters.

A Building Act Conviction Quashed.—Wood v. London County Council.—In the Queen's Bench Division on Tuesday, Mr. Justice Grantham and Mr. Justice Lawrance heard a case stated by the metropolitan magistrate at Westminster, after a hearing of a summons upon complaint by the London County Council that Joseph Carter Wood, the appellant, did, contrary to the provisions of section 7 of the London Building Act, 1894 (57 and 58 Vict. cap. ccxiii.), unlawfully commence to form and lay out a certain street for carriage traffic without having first made an application in writing to the County Council and obtained their sanction thereto. The question was whether a courtyard of some mansions in Victoria-street, Westminster, to be laid out for flats, was a street used for traffic so as to be amenable to the provisions of the London County Council under the Act. The magistrate had convicted the appellant. The site in question formed part of the site of the old Artillery Brewery and of a private house connected therewith. In 1891 the brewing business ceased. In 1894, after the passing of the London Building Act, the appellant decided to extend the building by erecting flats around a quadrangle. He gave notice to the district surveyor, but without asking the sanction of the County Council. The case stated that when the proposed buildings are completed by extending them round the other three sides of the quadrangle they will contain 42 flats (of which 14 are in the block already erected in Victoria-street), and will have two entrances and staircases leading from the quadrangle. There will also be an estate office, with a separate entrance. There will be no entrance from the quadrangle except by the archway in Victoria-street, which will be closed by lofty iron gates, and this archway and the quadrangle will be for the use of the tenants of the flats in the proposed new buildings and the tradesmen and others visiting them on business or pleasure, with or without carriages, and the public at large will be entirely excluded therefrom. The magistrate delivered his decision in these words:—"I found as a fact that the place in question was a street, and I held that the appellant had, under the circumstances, commenced to form and lay out for carriage traffic within the meaning of section 7 of the said London Building Act, and I accordingly convicted the appellant and ordered him to pay a nominal fine." Mr. Lawson Walton, Q C., for the appellant, contended this courtyard was only a curtilage of the building. He cited "Davies v. London County Council," "Pilbrow v. Vestry of Shoreditch," Nathan's Case. A courtyard laid out solely for the benefit of the tenant was not open to traffic within the meaning of the Act. Mr. Cripps, Q.C., for the County Council, urged that it was purely a matter of fact as to whether it was a street or not, and the magistrate had found that it was. The same remark applied to the finding as to the traffic, which might be a special traffic or a general traffic. In all cases cited the magistrate's decision had been upheld. He referred to "R. v. Shiel." The Court quashed the conviction. Mr. Justice Grantham said the question was whether the magistrate was right. The answer to that was that, in the opinion of both their Lordships, the magistrate was wrong. It was argued for the respondents that the Court ought not to interfere because the magistrate had found as a fact that this was a street, and it was said that other magistrates were entitled to find differently on exactly the same facts. The converse argument to this had been used by the junior counsel for the respondents in a former case. The magistrate, however, was not entitled to find as a fact that which the law did not allow to be fact. Turning to the facts, the owner had used the site of the brewery as a brewery for many years. In those days there were ways used by him for carts to the brewery. Those ways, in fact, were more like streets than the present courtyard would ever be. The appellant pulled down the brewhouse and stables, and proposed to build mansions round a quadrangle. The plot being pulled down, he proposed to leave a lawn, with a road round it wide enough for the carriages and cabs brought there by the tenants of the mansion. The whole thing was as private as could be. The appellant reserved the whole right of permitting people and carriages to come in. Could this be said to be a street for carriage traffic within the meaning of the Act? If it were, it would be necessary to get the sanction of the County Council, and the appellant would have to give a width of 40ft. for the drive and 20ft. for the footway, which would be absolutely useless. The case of "Davies v. London County Council" was not absolutely in point, but in it, and in other cases cited, a place such as the present was given as an instance of a place which could not be called a street. The Court was not asked to define the word "street," and did not mean to attempt it. No one had yet done so. All that the Court had to say was whether the place in question was a street. They thought it was not, that the magistrate was wrong, and the conviction must be quashed.

The Savoy Hotel Sky-Sign.—In the Queen's Bench Division, on Tuesday, before Mr. Justice Grantham and Mr. Justice Lawrance, a motion was made on behalf of the London County Council for a rule *nisi* for an order to Mr. Vaughan, the magistrate at Bow-street, to state a case in reference to an alleged sky-sign on the Savoy Hotel, kept up without a license. Mr. Avory stated on behalf of the London County Council that the London Sky-signs Act, 1891, did not include a solid board, but by the London Building Act of 1894, section 125, such a board was only excluded if it were 3ft. high or under. The board in question in this case, however, was some 7ft. high. It was 118ft. long, and fixed above the roof on an iron frame work. It was now a board of one face, with letters 5ft. high of embossed glass in a metal frame. It was visible against the sky from the Embankment and other places. At one time the letters had no board at the back of them. The magistrate had found the board not to be a sky-sign on the ground that the words in the Acts, "visible against the sky" meant such signs as showed the sky through them. There had, however, been a conviction in a similar case by another Metropolitan police magistrate. Mr. Justice Grantham said as there was a difference of opinion amongst the magistrates, a rule would be granted. Mr. Justice Lawrance concurred.

London Building Act, 1894, Secs. 59 and 73.—At the Lambeth Police-court, on July 16, before Mr. Denman, Mr. T. Sloman, of Albany-road, Camberwell, was summoned by Mr. Bernard Dicksee, district surveyor for East Newington, for non-compliance with a notice of irregularity, requiring him to carry up the party-walls 15in. above the roofs, as required by sec. 59 (i.), and to corbel out the party-walls 4in. beyond the eaves or cornices, as required by sec. 73 (i.). Mr. T. Seager Berry, instructed by the County Council, appeared for the district surveyor, and Mr. R. A. Kingsbury for the defendant. Mr. Dicksee gave evidence to the effect that on January 10 last notice was given him by the defendant of the erection of five new dwelling-houses, Nos. 26 to 34 (even), Bagshot-street, Newington, and that in the building of them certain irregularities were committed, and on May 10 he served upon the defendant a statutory notice (copy of which was produced) to remedy the same. Some of these irregularities had not been amended, and consequently the summons was issued. Since the commencement of the proceedings the defendant had amended certain irregularities in the back eaves mentioned in the notice by corbelling out the party-walls as required by witness, but otherwise nothing had been done. A diagram showing how the work had been executed, and how the Act required it to be executed, was put in and explained to the magistrate by witness. The party-walls had been carried up 13in. to 13½in. above the upper surface of the slates instead of 15in. as required by sec. 59 (i.). The irregularity complained of in the eaves was that a wooden facia or gutter board, which had been nailed to the rafter feet, projected beyond the face of the brickwork, the iron gutter was screwed to this facia, and a fillet of wood was nailed to the face of the facia to support the underside of the gutter; this facia was prohibited by sec. 73 (i), unless the party-wall was corbelled out 4in. beyond the eaves. Defendant had roofed in and practically finished the buildings since the irregularity had been pointed out to him. Cross-examined, witness said that he had measured the party parapets from the upper surface of the slates to the point where the parapet became less than 8½in. in thickness, the minimum thickness allowed by sec. 59 (i), the height above the rafters was 14½in. to 15in., the slate battens measured ¾in., and the three thicknesses of slates ¾in., making together 1½in. Asked whether he was willing to treat the facia as part of the roof, if it were completely covered with metal, he acquiesced, provided that the rules applicable to roofs were complied with so as to remove the facia from the operations of sec. 73 as a projection. Defendant then agreed to amend the eaves in this manner. Mr. Kingsbury argued that the district surveyor had measured the parapet in the wrong manner; he should have measured from the rafter, not from the slates. He quoted sec. 61 in support of this argument; in this section the roof was required to be covered with slate, tile, metal, or other incombustible material; therefore the roof existed before it was covered, and the roof must be taken to mean the rafters, not the covering of the roof. This practice had always been followed in the past. Mr. Denman said one object of a new Act was to abolish old practices. Mr. Berry pointed out that by Sched. I., Prelim. Rule I., every building was required to be inclosed by walls, and said nobody could contend that the walls were not part of the building; similarly, the roof was to be covered with slates or like material, but the roof was not complete without the covering; he contended the district surveyor's method of measuring was correct. Mr. Denman said the expression "above this roof" in the section must be taken to mean above the roof as a whole, and not above any particular part of the roof; the defendant was not entitled to dig down into the roof to find a point from which to measure. The measurement must, therefore, be taken above the surface of the slates; but the deficiency was small, and he therefore thought some arrangement might be made with the district surveyor. Mr. Berry pointed out that the district surveyor had no discretion in the matter; the section laid down a minimum, and that minimum had not been complied with. Mr. Denman finally decided to adjourn the case for 14 days, in order that the defendant might alter the eaves as arranged, during which time he would further consider the question of the party-walls. At the adjourned hearing on July 30, Mr. Berry said that the defendant had covered the wooden facias with zinc, but that was not sufficient to satisfy the district surveyor, as they should also have been set back flush with the face of the brickwork, whereas they still projected, and consequently were contrary to the section. Mr. Kingsbury objected that the defendant had done all that he undertook to do; he only agreed to cover the facias with incombustible material. Mr. Denman said that he understood that the defendant had made an offer to do certain work which the district surveyor had accepted, and he (Mr. Denman) had not taken particular notice of what had been agreed upon; but if the district surveyor was not satisfied, and the matter had to be argued out afresh, a new summons had better be taken out, as the work was now different from what it was at the first hearing. Mr. Berry argued that the case really stood where it was, as the notice of irregularity had not been complied with. With regard to the party-walls, there was another point which was not gone into at the first hearing. There were, in the rear of the houses, four water-closets in pairs; in these the party-walls were not carried up above the roofs at all; there were absolutely no party-parapets; the statutory notice and summons would cover this irregularity. Mr. Kingsbury objected that this matter was not mentioned at the previous hearing, and therefore ought not to be gone into; besides which, the roofs of the water-closets contained no woodwork whatever, and therefore no party-wall was necessary. Mr. Berry dissented. Mr. Denman thought that as these particular party-walls were not mentioned at the first hearing they should be made the subject of a fresh summons, or the case further adjourned. Ultimately Mr. Berry said that having regard to a remark that the magistrate had made at the first hearing as to the small amount of deficiency in the height of the party-walls of the main buildings, he would be willing, if the magistrate would give for future guidance a definite ruling of the subject, to withdraw the present summons, without prejudice to the question of the facias and the party-walls to the w.c. buildings. Mr. Kingsbury said that he had several witnesses to prove that the custom for the last 30 years had been to measure from the rafters. Mr. Denman said that he had considered the matter, and he was prepared to hold that the measurement must be taken from the upper surface of the roof, as contended by the district surveyor. The summons was then allowed to be withdrawn, defendant to pay £1 1s. costs to the district surveyor, it being understood that if necessary a fresh summons would be taken out for the irregularities in the facias and the party-walls to the w.c.'s.

Neglect to Give Notice.—Messrs. T. White and Son, of 52, Fairfield-road, Bow, E., were summoned at North London Police-court on Aug. 1 by Mr. A. Payne, district surveyor of East Hackney, South and North Bow, for commencing works in rear of 114, Cadogan-terrace without the notice required by Section 145 of the London Building Act. The defendant admitted the offence, but said it took place owing to a misunderstanding with his employer, the occupier of the house. The magistrate said that the notice ought to be given, and imposed a fine of 2s. 6d. a day from the time when the notice should have been given, and allowed 12s. 6d. costs.

Ancient Lights in the City.—Lord Battersea and Others v. the Commisioners of Sewers for the City of London.—In the Chancery Division, on Friday, before Mr. Justice North, a motion was made on behalf of the plaintiffs, the lessees for a long term of Weavers' Hall, in Basinghall - street, for an injunction to restrain the Commissioners of Sewers from building at 72 to 75, Basinghall-street in such a way as to obstruct the ancient lights of the plaintiffs. The plaintiffs stated that the building which formerly stood on the site now belonging to the Commissioners was 12ft. high to the eaves, and 19ft. 6in. to the apex; but the defendants were now proposing to erect a lofty building, for their offices, 66ft. 3in. to the eaves, with turrets, towers, and battlements considerably exceeding that height. Inasmuch as the proposed building is exactly opposite Weavers' Hall, the plaintiffs submitted that it would very materially obstruct their light, especially as the street was only 25ft. wide at the spot. The defendants contended that the building which was demolished to make room for the new building was a temporary erection on the site of a much higher frontage which was pulled down in 1875, so that they should be allowed to build on the scale they now intended. The Judge granted an injunction restraining the defendants from building a portion of the erection above a certain height, but gave leave to appeal.

CHIPS.

At the meeting of the Birkenhead Town Council on Wednesday a scheme for the improvement of two unhealthy areas, situated in Tunnel-road and Egerton-street respectively, was adopted.

The big tunnel on the new Sheffield Extension line to London is near Rugby, and corresponds to the celebrated Kilsby tunnel on the London and North-Western Railway. Half-a-dozen shafts are sunk already, and six more are in progress. The material is good for working, and almost free from water. Stone is very sparingly used in the construction, Staffordshire blue bricks being found better.

To-day (Friday) the Newcastle Society of Antiquaries will visit the Roman station at Aesica, on the line of the Roman Wall, some three miles from Haltwhistle. Under the guidance of Sir William Crossman and Dr. Hodgkin, the newly-excavated portion of the camp will be inspected and described.

The Meffan Trustees have acquired by purchase the large building, 12 to 16, West High-street, Forfar, the sum paid being £1,300. Miss Meffan, the legatee, died in 1879, leaving her trustees a large sum of money to be used for the moral and intellectual improvement of the community of Forfar. The sum left has now accumulated to over £6,000, and the trustees purpose demolishing the building they have bought and erecting thereon a Meffan Institute, which will contain a library, reading and recreation rooms. The new building will cost about £3,000, and the surplus of the trust will be held as an endowment.

The Hackney Vestry, in emulation of their neighbour Shoreditch, have decided to utilise the heat of their refuse destructor for steam-raising purposes in order that they may be able to introduce the electric light into their district. The scheme has been intrusted to Mr. Francis H. Medhurst, their consulting electrical engineer, who holds similar appointments for Bedford and several other corporations.

WATER SUPPLY AND SANITARY MATTERS.

Scheme of Water Supply for the Metropolis.—The scheme propounded by Mr. A. R. Binnie, the engineer of the London County Council, for a new water supply for the Metropolis, may (says the *Engineer*) be properly termed colossal, both in design and cost. Two of the reservoirs will be the largest ever constructed in this country. The works would possess a dual character, including two aqueducts, the largest in the world, one 150 miles in length and the other 176. The former would be the first to be constructed, the latter awaiting commencement at a subsequent date. Each is to convey 200 million gallons per day, and both are to be entirely covered over for their whole length. The northern or Midland Counties aqueduct will start from Hay, in the Wye Valley, and discharge into a service reservoir a little to the north of the Elstree Hills. The southern aqueduct would also pass from the Wye Valley, and would run parallel with the first as far as Chedworth, after which it would proceed by way of Hungerford, Basingstoke, and Guildford, to Banstead. Some deviation from this plan of the aqueducts is possible, but Mr. Binnie does not appear to recommend it. The proposed sources of supply are situated at altitudes ranging from 600ft. to 2,800ft. above the sea level, at the head-waters of the Rivers Usk, Wye, and Towy, in the counties of Cardigan, Brecon, Radnor, and Montgomery. The water will flow by gravitation into the service reservoirs; and the only pumping required will be for the small areas on the summits of Hampstead, Highgate, Shooter's Hill, and the Sydenham Hills. Such are the leading features of the project, which practically involves the abandonment of the present sources of the metropolitan water supply, except that derived from springs and wells in the chalk. The estimated outlay is £18,000,000.

Shrewsbury.—At special meetings of the town council, held last week, it was decided to carry out the schemes for the new water supply of the borough, and the interception and disposal of the sewage, prepared by Messrs. John Taylor, Sons, and Santo Crimp, of Westminster. The water scheme involves the construction of a large impounding reservoir, together with the necessary filter-beds, pumping station, service reservoir, and necessary mains for obtaining a Severn supply. As regards the main drainage, it is proposed to carry out a complete system of intercepting sewers, which will discharge at a central pumping station, from which the sewage will be pumped to land for purification. The schemes are estimated to cost about £85,000, exclusive of the cost of land.

In the parish church of Porlock, Somerset, which was restored in 1892 under the supervision of the late Mr. Sedding, new choir-stalls were last week erected. They are of oak, worked from the drawings of Mr. Sedding. In the front of the seats are panels carved in various devices. The ends of the seats are similarly treated, but each with different foliage. The poppy-heads, which are not so large as usual, are more ornately worked. The backs of the seats are chiefly in "linen work," but the clergy desks are elaborately carved. The whole work has been done by Mr. James Huish, of Porlock.

Mr. Thomas Codrington, one of the Local Government Board inspectors, attended the Leigh Technical School on Friday to inquire into an application of the Leigh and Atherton Joint Sewerage Board for sanction to borrow £45,207 for the purpose of sewerage and sewage disposal. The evidence given by Messrs. J. H. Stephen (Leigh) and E. Pritchard (London), engineers for the board, showed that the scheme proposes to deal with the sewage of the townships of Atherton and Leigh on farms held by the Leigh Local Board prior to the formation of the joint board in 1894. The estimated cost of the construction of joint sewers is £17,407 3s. 8d., whilst the cost of works on the farms is estimated at £27,800, making a total of £45,207 3s. 8d. The farms have an acreage of 228 acres; but at present it is only proposed to deal with 80 acres, leaving the remainder for future utilisation.

The will and four codicils of Mr. Francis Vigers, formerly head of the firm of Messrs. F. Vigers and Co., estate agents and surveyors, Frederick's-place, Old Jewry, late of The Mole House, Kersham, Surrey, who died on February 14, were proved on July 23 by Mr. Astley Vigers and M. George Vigers, the sons, and Mr. Edward Rushworth Keele, the executors, the value of the personal estate amounting to £9,125.

The school board for Leeds accepted at their last meeting tenders amounting to £14,117 18s. 6d. for a school to be built at Burmantofts. The buildings will accommodate 1,600 children in three departments, and will thus cost £8 16s. 6d. per head. At the same meeting plans were adopted for a new school for 750 children, to be built in Gledhamroad, Roundhay.

STATUES, MEMORIALS, &c.

Bury, Lancs.—A Runic cross has recently been erected in St. Paul's-churchyard to the memory of the late Mr. Lawrence Booth, architect, of Manchester and Bury. The cross is 5ft. 6in. in height, and stands on a solid stone base 2ft. in depth. The whole of its front surface is worked into panels with carved interiors, the four panels in the top portion being filled with Masonic emblems to illustrate the various ranks which the late Mr. Booth held as a Mason—viz., Craft, Past-Master, Royal Arch, and Mark Mason. On the front of the stone base is the following inscription, the letters of which are let into the stone with lead:—"In loving memory of Lawrence Booth, F R.I B.A. Born March 17th, 1837. Died July 25th, 1894." The cross, which is of Macclesfield stone, has been executed by Mr. J. Rawson, of Knowsley-street, Bury, from a design prepared by the late Mr. Booth's eldest son, Mr. Richard Booth.

York.—Mr. Hamo Thornycroft's recumbent figure of the late Archbishop Thomson, in York Minster, has been placed upon the tomb erected some time ago, and the unveiling takes place with due ceremony to-day (Friday). The effigy, which is life-size, is sculptured in cream-coloured statuary marble. His Grace is represented in his archiepiscopal surplice and bands. His hands are clasped, and a favourite dog rests at his feet. The statue has been carved out of a solid block of marble. The canopy and altar tomb, designed by Mr. G. F. Bodley, A R.A., are Early Perpendicular in style. The plinth and step of the altar tomb are of Belgian black marble, and the step is paved with black marble of the same description and white Carrara marble. The remainder of the work is of white Tottenhoe Clunch stone from the Bedfordshire quarries. The front of the tomb is divided into nine panels, filled by figures of angels. The panelling is surmounted by a moulded slab of marble, on which the sculptured effigy has been placed. Round the edge of the tomb there is a Latin inscription on brass, and on each side are buttresses, with pinnacles, rising from the base to the cresting on the canopy, in which are traceried windows, perforated and enriched with crockets, finials, and other ornamentations. The whole is surmounted by cresting elaborately carved, in which roses from a conspicuous ornament. The canopy is groined beneath with fan-groining, terminated by pendants, and there is a carved inscription, intersected by a floriated cross just below the groining.

CHIPS.

According to the designs of Mr. H. H Bridgman, C.C., F.R.I B.A., the St. Pancras Female Orphanage, Hampstead-road, is about to be rebuilt at a cost of nearly £6,000.

The Glasgow Dean of Guild Court have just approved of Mr. Frank Matcham's plans for the reconstruction of the Gaiety Theatre, which is to be converted into the Empire Palace. Operations will be begun in October and finished about the end of the pantomime season.

An ornamental recreation ground at the southernmost extremity of the Isle of Dogs was opened to the public on Saturday by Mr. W. Crooks, chairman of the North-East District Parks Committee of the London County Council. The land has an area of three acres, and is opposite the front of Greenwich Hospital.

A new reading-room at Springfields, Wolverhampton, built by a bequest by the late William Butler, of that town, was formally opened on Friday. Mr. J. Lavender, of Wolverhampton, was the architect, and Messrs. J. Bradney and H. Lloyd were the contractors.

The Liverpool Corporation have acquired the Liverpool Electric Supply Company's undertaking for the sum of £400,000, subject to the approval of Parliament. The corporation also agreed to pay any sum which the company have expended on capital account for the benefit of the concern over and above its share capital.

The school board for Watford have appointed as architect for their proposed schools in Fearnley-street, Mr. C. P. Ayres, of that town, whose design was selected in competition.

The most serious fire that has happened in the centre of Birmingham since the destruction of Marris and Norton's furniture establishment occurred on Friday night in Paradise-street, and resulted in the entire destruction of the interior of the premises of Messrs. J. R. Lee and Co., decorators and workers in stained glass. The building consisted of four floors in Paradise-street, with a modern stone front to that thoroughfare, and having basement and sub-basement; the premises extended backwards in four stories as far as Swallow-street. The front rooms were occupied as stock and show rooms, the basement was filled with a large quantity of oils, varnishes, and other materials, and industrial operations were carried on at the rear.

Our Office Table.

Mr. Cecil Harcourt Smith, of the Department of Greek and Roman Antiquities in the British Museum, has been appointed by the managing committee of the British School at Athens director of the school for the next two years, in succession to Mr. Ernest Gardner, who has held the office since 1887. The Trustees of the British Museum have, with the concurrence of the Treasury, given Mr. Smith special leave of absence for the purpose. Since the meeting held by the Prince of Wales at St. James's Palace on July 9, a number of additional subscriptions and donations have been promised in support of the work of the school.

In the course of the excavations that are being carried on by the Greek-Archæological Society on the site of the ancient city of Mycenæ, in continuation of the work of the late Dr. Henry Schliemann, several more prehistoric tombs have been discovered and opened. Among other objects, M. Tsountas, the Inspector of Antiquities, has found two mirrors of brass, two poniards of copper, seven rings of gold without ornamentation, and twelve others adorned with various figures.

The new art gallery which Mr. Tate is building on the site of the old Millbank Penitentiary, as a gift for the nation, has already risen to a height of some 20ft. above the ground level, and all but the lofty central portion will probably be roofed in before the winter. The whole will, it is expected, be completed in another twelve or eighteen months. Mr. Sidney R. J. Smith, the architect of the gallery, considers that the pictures may be displayed in it with very little delay after completion, as the walls are to be lined not with plaster, but with wood, and as the roofing-in will shortly be done, there will be ample time for the necessary drying. The remaining portion of the land will be utilised as the sites for a small military infirmary, a hall for Civil Service examinations, and some model dwellings to be erected for the London County Council.

At the last meeting of the town council of Glasgow an animated discussion took place as to the purchase for £400 by the Art Committee of a portrait of Cornelius de Witt, by Van der Helst, as an addition to the permanent collection. A. M. Shearer asserted that this was a sort of picture that only strangers to Glasgow could appreciate, and very few of them. It would have been better to buy £400 worth of grocers' calendars and send them through the community! As the picture had been bought from the surplus derived from admissions to the picture exhibitions, the matter dropped, although two or three other members thought the purchase a bad bargain.

The report to the Livery of the Carpenters' Company for 1895 states that the expectations expressed in the last report, with respect to the result of the examination at the Stratford Institute, have been more than realised, the grant received from the Science and Art Department being considerably larger than in the previous year. The Court believe that much of the success of this institute is owing to the personal supervision given by various members of the company. The Livery had lately the opportunity of seeing the buildings now complete. More warm baths have been added since the last report, and both these and the swimming-bath are more largely used than ever. The work at Titchfield-street, W. (formerly the West London School of Art), is also of the most satisfactory character. To the classes mentioned in the report of last year is now added one for plumbing. Every effort was made to induce the Plumbers' Company to join; but as they did not seem willing, the Court determined on starting one themselves, and opened with 16 students, about as many as there is accommodation for; in fact, the whole building is now almost fully occupied. At the close of last year lectures were given to those intending to sit for examination on sanitary matters, and in December 41 came up for examination, of whom 30 gained a certificate. In the spring a course of popular lectures was given to large audiences. A course of purely practical lectures was given in May to candidates for examination in carpentry and joinery, and there was an average attendance of upwards of 100. Seventeen went in for the examination, of whom five gained first-class and seven second-class certificates. The technical library continues to be largely used, and the Court draw attention to the gift of Mr. Henry Harben, the late Master, of the bookcase and its contents which stands in the drawing-room. The classes at King's College and University College are being carried on with vigour, and the numbers of the latter show a considerable improvement. The classes for wood-carving at King's College have been very satisfactory, and the work done by the students there, and sent to the exhibition last month, showed a marked improvement on former years. Those at Titchfield-street confined to the trade have somewhat fallen off in numbers, but the wood-carving trade has experienced a time of great depression, which may possibly account for it.

The Yorkshire Branch of the Sanitary Inspectors' Association held a general meeting at Huddersfield on Saturday. Inspectors first visited the Hillhouse refuse destructor, and returning to Huddersfield, were entertained to lunch in the Mayor's reception-room at the Town Hall, by the Health and Sanitary Committees of the corporation. The members were afterwards conveyed by a special tramcar to the borough sewage outfall and purification works at Deighton. These works, which, with the land, have cost about £100,000, were inspected with much interest, attention being called to the comparatively clear effluent from the tanks, as compared with the inky and repulsive character of the sewage before it passed into the works. Mr. R. S. Dugdale, C.E., the borough engineer, acted as guide, and described the works in detail. Alderman Jessop, at a subsequent meeting in the board-room, stated that the corporation were not tied to any particular system of purification. In the No. 1 tank they were at present experimenting on the International Sewage Purification Company's system. The cost of the chemical precipitant was 28s. per million gallons of sewage purified, and if that system were adopted, in the whole of the 24 tanks at the works, the cost per one million gallons would be 16s. Having returned to the Town Hall, the members heard an address from Mr. R. W. Cass, surveyor and inspector of Pudsey, on "Some Important Details in Drainage and Sewerage." Mr. T. Pridgin Teale, of Leeds, president of the branch, occupied the chair. Mr. Cass dealt chiefly with the defects noticeable in house-drains, pointed out where mady of the arrangements were at fault, and laid a heavy hand on the too-often scamped work of the jerry builder. By a series of diagrams, photographs, and models, he clearly illustrated the manner in which dwellings often became insanitary, and how such serious evils might be overcome.

The new City and Waterloo Railway, says a daily contemporary, has got quite clear of the river. One end has pushed up into Stamford-street, and is making rapidly for Waterloo; the other has burrowed under the District Railway near Blackfriars Station, and is just entering Queen Victoria-street, where it will have above it not only the underground line between Blackfriars and Mansion House, but a main sewer that runs under that. Plans for the two terminal stations are now being elaborated, and negotiations are proceeding with the new Central London Company for determining the details of the connection between the two lines underneath the roadway in front of the Mansion House.

The extensions of the Thomason Hospital, Agra, are illustrated in *Indian Engineering*. The building is in a Gothic style, treated in a semi-Indian manner, the walls of brick pointed externally and plastered internally. The new buildings comprise a dispensary-block, one public and two private wards, a European ward, and subsidiary buildings. The public ward is the chief addition. The plan shows a long building surrounded by a verandah, with Tudor-shaped arches and a tile lean-to roof. The two wards are each 60ft. by 22ft., and are separated by a passage or corridor in the centre, connecting the front and back verandahs, and giving access to the wards, &c. The main roof of ward is also of Allahabad tiles on *sâl* wood trusses. The floors are of mosaic; the walls are painted with silicate paint to 6ft. high round wards, and panelled cloth ceilings are put up in the European ward. Scouring sluices for flushing and cleansing the floors have been provided in all the wards. The designs were prepared by Mr. C. J. Sheridan, executive engineer, and carried out by Mr. Murphy, district engineer.

Trade News.

WAGES MOVEMENTS.

Edinburgh.—At a meeting of the Edinburgh and Leith Master Builders' Association, held on Tuesday night, it was unanimously agreed not to entertain the demand for an increase of joiners' wages, it being considered that the state of trade did not warrant it.

CHIPS.

A tower is about to be added to the church of St. Bartholomew, Bolton, as a memorial to the Rev. H. Loxham.

A new bridge across the Seine at Paris, joining the Quai de Javel to the Quai d'Auteuil, has just been finished. The bridge, which is to cost altogether 2,000,000 francs, was begun two years ago, and is to be called the Pont Mirabeau.

At a special meeting of the Pudsey District Council, the No. 4 section of the Pudsey sewerage scheme has been let to Messrs. Garforth Bros., of Mirfield, for £1,924. This section includes the whole of the Waterloo, March, and Gibraltar portions of the township.

At the closing meeting of the annual congress of the British Medical Association, held in London on Friday, a resolution was adopted declaring that in the interests of the public health, and in justice to provincial medical officers, it was desirable that they should enjoy the same security of tenure as is enjoyed by the poor law medical officers and London medical officers of health, and also Scotch medical officers.

A purchase has just been made, on behalf of the Nelson Corporation, of eight acres of land, situate on the higher side of the town. The land, which will be laid out as a park, has been acquired for about £300 per acre.

A proposal is on foot for establishing a new secondary school at Shepton Mallet, to supersede the present grammar school. Towards the outlay that will be involved the governors of Sexey's Hospital will contribute £1,500, and the Somerset County Council £750, while £800 has been subscribed locally.

A new lighthouse on Spurn Point, Yorkshire, will be brought into use next month. The light will be visible seventeen miles off, the lantern being at an elevation of 120ft. above high-water mark. There will also be three subsidiary and distinct lights—two at 60ft. above high water, and one at 45ft. The lighthouse, which is built of Staffordshire brick, stands on a very narrow spit of land, and has been erected by the London Trinity House.

At a recent meeting of the guardians of the Pontefract union, the unanimous decision of the building committee for the appointment of Mr. J. H. Greaves, of Leeds and Pontefract, as architect for the new laundry and washhouses, porter's lodge, and vagrant wards, was confirmed by 35 votes to 2. The new infirmary, recently erected from the designs of the same architect, is now near completion, and will accommodate 100 beds, at a cost of £7,000, the contract for which has been successfully carried out by Messrs. H. Arnold and Son, of Doncaster.

The subscriptions to the rebuilding fund of St. Peter's Church, Oldham, now amount to £6,311. An effort is being made to obtain £7,000 by the end of the year.

The Wilmslow District Council, on Thursday in last week, considered tenders for the construction of the northern sewerage scheme. After some discussion, the Council decided to accept the lowest, that of Mr. J. A. Ewart, of Warrington, the amount being £5,279. The work is to be proceeded with at once. The outfall works are to be constructed on land near Styal, which had been purchased from the Chorlton Board of Guardians. Mr. Bowden is the engineer.

The members of the North-Western Sanitary Inspectors' Association will visit Darwen tomorrow (Saturday) by the invitation of the mayor (Mr. William Pickup) and corporation of that borough.

Messrs. Fambrini and Daniels, Architectural Concrete Works, Lincoln, have secured the contract for supplying a series of 26 tracery windows for St. Wilfred's Catholic Church, Hull. The above are of various sizes, those for the sanctuary being 16ft. high. Messrs. Smith, Broderick, and Lowther, Hull, are the architects.

A Local Government Board inquiry was held on Friday at the Courthouse, Stockport, by Mr. Thomas Codrington, concerning an application to the Local Government Board by the Stockport town council to borrow £37,636 for purposes of street and bridge improvements and public parks, also for £2,024 for the extension of the technical school.

A column of red granite erected at Uxbridge to the memory of John Bedford Leno, the veteran Chartist and Socialist, was unveiled in the presence of the members of the Hotspur Club on Sunday.

The United Asbestos Company, Limited, of Dock House, Billiter-street, London, E.C., have been awarded the contract for the supply to the Admiralty of asbestos packing and other goods for the ensuing year, 1895-6.

The parish church of St. Martin's at Brighouse, which has been closed for the purpose of restoration, was reopened on Thursday in last week. The principal alteration has been the re-pewing of the church and the building of a new porch. The sermon was preached by the Bishop of Wakefield.

A newly-erected Primitive Methodist church and schools in Front-street, Shotley Bridge, were formally opened on Saturday afternoon. The building, which supplants incommodious and inconvenient premises in Wood-street, has been erected at a total cost of £2,100. There will be accommodation for 400 worshippers.

Mr. George Woofenden, of Kenwood Bank, Sheffield, who died last June, has left some munificent bequests to his native place. His will has just been proved at £134,000, of which £120,000 is to be devoted to the erection and endowment of convalescent homes and almshouses.

The memorial to the late William Charles Fynes Webber (1815-81), consisting of a tablet in Dove marble and a medallion portrait in Carrara marble, has just been placed in the crypt of St. Paul's Cathedral. The design is by Mr. F. C. Penrose, P.R.I.B.A., architect to the Dean and Chapter.

The tender of Messrs. Dorse and Co., of Cradley Heath, Staffordshire, has been accepted for the erection of new engineers' shop and offices, at Cradley Heath, for J. Stevens and Co. Tender A, not providing bricks, £1,700. Tender B, providing bricks, £2,400.

The Watching Sub-Committee of the Aberdeen Town Council recommend that a new fire station should be erected on the site of the existing establishment in Frederick-street. It is also proposed to have a permanent staff of firemen. The estimated cost of the building, including apartments for the lighting and weights and measures department, is £9,000.

The town council of Grimsby have received a report from the highways committee recommending that the salary of Mr. M. Petree, the borough surveyor, be increased at once from £350 to £400 a year, with an annual increase of £50 for the next two years, making the ultimate salary £500 per annum; and also that the salary of the assistant surveyor, Mr. Heap, be raised from £130 to £150, and then by annual instalments of £25 till it reaches £200.

Mr. Wolfe Brennan, C.E., Oban, has been engaged to survey and make up a probable estimate of the cost of constructing the proposed railway line connecting Loch Fyne with the West Highland Railway. This new line will run up Glenkinglas, striking across to Loch Sloy, joining the West Highland line at Inveruglas.

After having undergone extensive alterations and improvements, the parish church of Ledbury has been reopened. Amongst the more noticeable innovations are an oak altar and five stained-glass windows. The cost of the restoration has been nearly £5,000. Mr. J. L. Pearson, R.A., was the architect, and Messrs. Bunning, Camberwell, were the contractors.

The first school erected by the Birkenhead School Board, that in the Woodlands, off Borough-road, was formally opened on Tuesday. The school will accommodate 979 children, but additional rooms, which may be utilised for special purposes, provide further accommodation for 228 more children. It is built in two blocks, and consists of one story only throughout. The buildings externally are faced with pressed bricks, and internally the various school and classrooms have wood-block floors on concrete. Mr. John Shaw, of Birkenhead, was the general contractor, and he has carried out the work from the designs and under the superintendence of Mr. Charles Wise, architect, Liverpool.

The Vestry of St. Mary the Virgin, Aldermanbury, E.C., have decided to accept the offer of Mr. C. C. Walker, of Lilleshall Old Hall, near Newport, Salop, to erect a granite memorial in the church to John Hemming and Henry Condell, both of whom were fellow actors of Shakespeare and parishioners of Aldermanbury.

The efforts of the British Archæological and Antiquarian Associations to better preserve Stonehenge have been attended with considerable success. They found in Sir E. Autrobus, the owner of the soil, a man who was eager to aid them. As a result of the negotiations between the societies and Sir Edmund, a responsible person is placed at the stones who has practical charge of them, and whose business it is to prevent any iconoclastic stupidity on the part of visitors.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2119.
FRIDAY, AUGUST 16, 1895.

"AS OTHERS SEE US."

WE gave last week an abstract of a very kindly and, as it seems to us, a very reasonable, criticism of London architecture from an American point of view. Mr. Barr Ferree, who contributes it to the *Architectural Record* of New York, deals with both the weaknesses and the successes of English architects; and it is interesting to see how far his estimate, in each case, agrees with our own.

We are still uncertain, he thinks, what style to follow. Our fashions change too rapidly—one wave of foreign influence succeeds another—and before we are fairly at home in any mode of design, we cast it aside and take up a different mode. This is perfectly true. We waste our strength in trying to pick up the last new way of expressing ourselves, when it would have been better to use it in finding something new to express. Most of us follow the new simply because it is new, not because we particularly like it. It is only one man here and there, probably, whose heart is really in the mongrel Renaissance of the hour. It gives no scope for doing anything that could not be done much better in some type or other of archless Gothic. It is in no way more convenient, or more flexible, or more in harmony with modern surroundings. But two or three clever men began it, and as the multitude do not like to be left behind, they all tried to use the same forms, without the same cleverness. This fancy will soon have had its day, and then some people threaten us with Renaissance of a still more dismal type. We are to have Wren's style without Wren's genius. There are to be more Royal Exchanges, more Regent-streets, more Marble Arches, probably, and we are adjured to put up with them because they are so "very English"! They strike Mr. Ferree as having been designed under French influence; but, in any case, he thinks the recent examples totally uninteresting. Does anyone—except, possibly, their designers—think otherwise?

The utterly ignorant architecture which characterises so much of the City appals our critic. Its death-like dulness, its negation of ideas, its complete subservience to commercialism, impress him as more than mortal; and as mere carelessness hardly accounts for them, he asks whether they are not intentional and studied. Mr. Ferree has evidently never heard of the speculative "architect," 90 per cent. of him speculation, and the rest surveying. He haunts the City, and adorns the Institute; for he is one of the inartistic who prosper in the world. He knows how to make his profession pay. He departs at last, universally respected, and it is only to be regretted that his works do not follow him. But turning from charlatans and pretenders to men who, more or less, deserve the title they bear, the general picturesqueness of their works is what strikes our visitor. This is one of the chief ends, he says, at which London architects are striving. No doubt this is so, and no doubt, also, they sometimes strive not wisely, but too well. But, of the two ways in which a town can be built—the regular and the picturesque, it is the latter alone which suits our conditions. It is in harmony with our independence and individualism. Every Englishman likes to do what is right in his own eyes. He wants all the freedom he can have without trespassing on the freedom of others; and sometimes, we fear, even more than that. He has not much faith in State interference, and State regulation. He may put up with it, after a good deal of grumbling, in what he recognises as important matters, such as light and air, and sanitation; but he is not going to be compelled, for the mere look of the thing, to make his floors and windows, and cornices, range with the floors and windows and cornices of his next-door neighbour. They may do that in Paris if they like; but "Britons never will be slaves." Perhaps, by chance, his decision is on the side of art as well as of liberty. London is not laid out for formality, and a London atmosphere is not the thing to make formality look well. Oftener than not, long horizontal lines of buildings, even if we had them, would be lost in the distance, and not seldom, they would be quite invisible. But we can generally see the skyline of the ten or twenty houses nearest to us; and the thing that answers best, therefore, is to get an effective skyline. Obviously it is much easier to attain this with a lot of independent and comparatively narrow fronts of varied height, than with one long façade; and so the Londoner's impatience of control may be all for the best.

We just said that London is not laid out for formality. That is true as to the older streets and the underlying scheme of the whole. We wish it was also true of the newer thoroughfares, and of those now projected. But as to these, there is a constant discordance between the streets and the architecture, which is only the outward and visible sign of a conflict between boards and vestries and councils on the one hand, and people of artistic tastes on the other. When a new line of traffic is proposed, the one idea of the average councillor, and of the average engineer who advises the council, is to make it a perfectly straight one. It looks so nice on the map, and if it costs some millions more than it would do if the board reserved the option, in negotiating with the owners of the ground they are buying, to curve it a few yards to the right or the left—well, so much the better for the owners. But it is not so much the better for London, any more than it is for London ratepayers. Picturesque architecture goes best with picturesque streets, which allow it to be seen from varied points of view; which let you come on it unexpectedly, and not always have it in prospect as far as the state of the air will admit. A very little curvature indeed will do this—a little break, here and there, in the soul-wearying straightness of the road. It would be too slight for inconvenience to be thought of in connection with it; the lengthening of the way would be imperceptible, but it offends a popular superstition. Bumble and Co. want to make London formal; cultivated persons generally want to make it picturesque; and though Bumble and Co. cannot possibly get their own way in this matter, they can partly hinder the cultivated persons from getting theirs. They have the satisfaction of keeping London from becoming beautiful in the only way in which beauty is possible to it, and they have the assurance to go about at the same time, saying, "See the wonderful improvements we are making." But perhaps this only describes what has been. We may have entered a new era. Let us keep a sharp eye on the "Council Broadway."

Some points of arrangement in English buildings, which we are so accustomed to that we never think twice about them, strike Mr. Ferree as peculiar; he deems them more defensible in houses than in business premises. Here we are inclined to differ from him. House basements, when occupied, as they generally are, by kitchens, sculleries, and the like, are objectionable in many ways. They are far from healthy for the servants employed there. They cause a great amount of needless labour, in running up and down stairs, and in carrying up dinners, luncheons, and everything that belongs to them, and they are an effectual means of diffusing the smell of the cooking all over the house. Most of these faults are not found in basements used for trade. They let at a high rent, and allow an extra story to be provided at the bottom of a structure, where our regulations as to the heights of buildings would not permit it at the top. Still, on sanitary grounds, basements are not to be greatly encouraged anywhere. If London had just been totally destroyed and were about to be rebuilt, it might be well to start again without them. But as it is, the architect who rebuilds, or who builds a new office or warehouse which adjoins an old one, generally finds that his neighbours have basements, and that he must take his party-walls down to their level so that the question is practically settled apart from his own preferences.

We turn to the criticisms on particular works. Many of them come in for very high though discriminating praise. The New Admiralty, however, is described as of commonplace design, and the new Record Office does not fare much better. The addition to the National Gallery is looked upon as rather excusable than admirable. The Law Courts produce in our critic the same feelings of mixed admiration and disappointment with which we are familiar here. But we think that Street was right in the principle he adopted of breaking up the front into a series of masses, to be seen one after another. The great external weakness of the work is in its central mass, in the recessing of the great hall behind the buildings which flank it. Very few façades with a recessed centre are really successful, and this is not one of the successes. On the other hand, there is great beauty in many of the subordinate masses, not merely in the Strand, but in the north elevation. The detail in general is admirable, both inside and out. Altogether it is the work of a man of genius battling with great difficulties; not only the difficulties of site and arrangement, but the much greater and quite unnecessary ones imposed by the perverseness of self-conceited officialism. No doubt there is plenty of this all over the world; but in England we seem to be endowed with a double portion. From the greatest national work down to the smallest chapel or school, everything here is marred by the interference of ignorant committees, without knowledge, without taste, and too often without fairness or honour or conscience.

If, as Mr. Ferree says, the Imperial Institute fails to accomplish the specific purpose for which it was erected, that is certainly not the fault of its architect. The fact is, that the promoters of the scheme did not know, from the first, what it was they wanted. Somebody who had been reading about the movement for a closer union of England with the colonies thought that a central building in London, where English and colonial men of business could meet and exchange ideas, would be a good thing. Then he, or someone else, hit on the name of "Imperial Institute" for it. Plans were invited, in a limited competition, for an Imperial Institute, whatever that might be. One of the competitors thought it was one thing, and another competitor another, and the vagueness of the whole affair was their trouble. The promoters aimed at nothing definite, and they have attained no definite success, except in adding to the South Kensington group of buildings another which is externally the most striking of them all. We do not agree with Mr. Ferree that the Imperial Institute errs on the side of too much picturesqueness; but we do agree with him that it has too much detail, considering how tame and unmeaning much of the detail is. As a whole, however, the exterior groups together very finely; but it is less satisfactory on a near approach than when seen from various points in Exhibition-road.

The Natural History Museum is the text for another lecture on the tendency of London architects to over-elaboration of detail—a lecture which is well deserved, and a text which is well selected. The Museum has much about it that is admirable; but partly, perhaps, from the nature of the material, its ornament often looks coarse, mechanical, and misplaced. The mouldings, perhaps, are not much larger than Romanesque ones in general; but the fact of their being in terracotta makes them hard and staring and aggressive. It may be questioned, too, whether the animal sculpture or modelling in the interior is not a mistake. It is too much in the vein of the popular designer, who, when he shapes a vase to hold flowers, thinks it the appropriate thing to paint flowers all over it. But painted flowers look poor beside real ones, and terracotta beasts besides stuffed ones. We can put up with reminiscences of nature when nature herself is away, and only then. To some of us the internal sculpture of the Natural History Museum is a very jarring element. It takes off the attention from what one has come to see, and it does not reward the attention it has attracted.

Domestic architecture and churches, in their best examples, find almost unmixed commendation. But here, as everywhere else, the multitude think that to copy an able man's style is to become his equal; and every successful house leads to a lot of unsuccessful imitations. It is the same in every art—at least, since the arts have become disorganised. It is the way of the modern world, and the price, perhaps not too high, which we pray for freedom.

PARTY-WALLS ABOVE ROOFS.

HOW a party-wall is to be measured above roofs is a point which has just been decided upon by the magistrate of the Lambeth Police-court, Mr. Denman. The question had been raised in connection with a summons taken out by the district surveyor for East Newington for non-complying with a notice of irregularity against a builder, defendant. According to section 59 (i) of the London Building Act, 1894, every party-wall shall be carried up 15in. above roof, measured at right angles to the slope of the roof, or 15in. above the highest part of any flat or gutter, as the case may be. Such height applies to buildings other than those of the warehouse class. The defendant appears to have carried up the party-walls of five dwelling-houses 13in. to 13½in. above the upper surface of the slates, instead of 15in., as required. Another irregularity referred to the corbelling out the party-walls 4in. beyond the eaves or cornices, as required by section 73. A wooden facia-board had been nailed to the rafters' feet, and projected beyond the face of brickwork, and the iron gutter was fixed to the facia. The Act required that the facia in such a case should be stopped by corbelling out the party-wall 4in. beyond the eaves. The defendant had practically roofed-in and finished the buildings since the irregularity had been pointed out. The district surveyor, in cross-examination, said he had measured the parapets. The height above the rafters was 14½in. to 15in., the slate battens measured ¾in., and the three thicknesses of slates ¾in., making 1½in. together. Defendant agreed to amend the eaves as required by the district surveyor, the facia was covered with metal, and the party-wall corbelled out as required; but the main contention remained as to the height of party-walls above roof. It was contended for the defendant that the district surveyor had not measured the parapet in the right manner; that he should have measured from the rafter, not from the slates, and sect. 61 was quoted in support of this view, which says the roof "shall be covered with slates, tiles, metal, or other incombustible material." From this he affirmed that the roof existed before it was covered. On the other side it was argued that the roof was not complete without the covering, and therefore the district surveyor was right in measuring the height of parapet from the slates. It was this little altercation between the contending counsel which formed the main argument. Are the words "of 15in. measured at right angles to the slope of the roof" to mean measured to the top of the rafters or to the slate surface? There is just a doubt about the question, which shows the need of revising the section by the addition of explicit words defining the actual surface. Reading between the lines, the meaning is, no doubt, that given by Mr. Denman—namely, that the measurement "must be taken from the *upper surface* of the roof." The latter part of the same clause, which reads "or 15in. above the highest part of any flat or gutter," seems to imply the meaning that the upper surface is intended; but this argument was overlooked. Mr. Denman's ruling is at least reasonable. He said the expression "above the roof" in this section must be taken to mean above the roof as a whole, and not above any particular part of the roof; the defendant was not entitled to dig down into the roof to find a point from which to measure. The measurement must, therefore, be taken above the surface of the slates; but the deficiency was small, and he therefore thought some arrangement might be made with the district surveyor. After another hearing of the case, the representative of the L.C.C. agreed to withdraw the summons as to the height of party-walls without prejudice to the other irregularities complained of, on the understanding that the magistrate would give for future guidance a definite ruling on the subject of the measurement of party walls. This Mr. Denman did, as we have seen.

We have here another instance of the need for clear definition. When certain measurements are enacted, the material or surface from which they are taken ought to be very plain, and avoid any risk of misapprehension. The word "slope" of roof in this connection is, for instance, unnecessary, as it only implies inclination, whereas surface has a more tangible and distinct meaning if used with a qualifying adjective. Other instances will occur to the reader, such as the dispute in terms "party structure", and "old" and "new" buildings. What, for example, is a "new" building or an addition to an "old" building has been a matter of disagreement. The late Lord Coleridge ruled it was a question of degree; if a building were nearly all taken away and then rebuilt, it would be a new building. On the other hand, it is quite clear that by a small addition of, say, a door, the building would not thereby become a new building, and between these extreme cases there may be thousands of others. It would not be possible to give a definition applicable to each particular case. Much is therefore left to the discretion of the judge, with somewhat doubtful results. But we think a "new" building ought to be defined to be one that has been reconstructed to a certain proportion of its former extent, and the definition in the London Building Act, "taken down for more than one-half of its cubical extent and re-erected after the commencement of this Act," appears to be reasonable. But there are other definitions, as that we have been discussing, which admit of no degrees: it is a matter of clear description, in which case every ambiguous word ought to be expunged. The height of a party-wall above the roof of a building is a point of vital importance, and it is essential that no diminution from the statutory height be permitted.

SPANNING SPACES.

IF we were asked what was the greatest and most momentous building problem that has been the motive of every great architectural style in the past, we should certainly answer it was the problem of spanning openings and covering spaces. Both these requirements, no doubt, arose contemporaneously, and both exercised a very marked influence on the architecture, for it was the development of the former which gave the varieties of facial expression to buildings, and that of the latter which exercised so potent an effect on the plans and contour of structures of all ages. From the early trabeated or Greek expression to the latest invention or fancy of the Renaissance architect we have an inexhaustible variety of types, each one of which has swayed the destinies of a style. No professional reader will want examples. They are to be seen in every national style in which there has been a genuine growth, and in every historic building. No less has the mode of covering areas exercised an influence on style. The change from the flat to the arched roof is of interest. From the square Hall of Xerxes, which, according to Fergusson, covered 105,000sq.ft., was larger than any Greek temple, and was covered with a flat, wooden roof, supported by numerous pillars, in seven bays, to the Pelasgian tomb houses at Mycenæ, which was circular, and 48ft. in diameter, and was covered by an equilateral pointed vault, with horizontal layers of stone, there is a decided step in advance. Not that the real principle of the arch was unknown, for there are, upon the authority of Layard, Hoskins, and others, chambers round the Egyptian pyramids roofed with stone and brick arches; but these constructions were of a limited kind, and the arch seems to have been confined to small tombs, or chambers, or vaulted drains. The Pelasgian or Etrurian treasuries or tombs had scarcely any direct influence on style, for they were covered by earth, and not visible, and it has been shown that the horizontal-course system of arch construction was not confined to the Pelasgic races, but were adopted in India and Asia Minor. They, at least, prove that the principle of arch construction was known long before it was applied boldly as an architectural feature. The horizontal arch was quite safe so long as it was equally weighted externally by earth or by masonry; but it was reserved for the radiating principle of construction to accomplish the great feats which developed into typical forms of architecture. Step by step we see the progress made. First the dome was made an external feature. From the round temple at Spalatro, or the Pantheon rotunda, whatever its age, to the beautiful temple of Minerva Medica at Rome, with its dome of 80ft. diameter resting upon a polygon made up of circular niches or alcoves, there is a decided advance. The pendentive system is adopted at the angles, the arch is built on the radiating principle with ribs of tiles between, which is filled by lighter material, and the plan of concentrating the material of the arch at certain points supported by external buttresses is recognised. Circular or polygonal structures were thus the earliest development of the arch, as we find in many of the Roman temples and in the Christian baptisteries of a later age. Next we have the more complex circular church of St. Vitale, Ravenna, an octagonal structure of 110ft. diameter, its inner dome of 50ft. forming the clerestory above the sloping roofs of the octagon aisles and galleries. The builders here attempted to vault a space with the least thrust by using earthen pots instead of stone masonry, and this vault is brought down to the octagon, the angles being cut off by squinches. Here the vault is lightened and covered externally by a low timber-framed roof, being one of the first examples of the later vaulted construction. The vault was internal. It is not so skilful an example of vault construction as its Roman prototype, which visibly exposed the vault. There are no ribs to concentrate the trust, no buttresses; but it shows that the problem was understood, and how economy of material and weight could be insured. The church of San Lorenzo, Milan, is a further step; the dome is octagonal, 70ft. in diameter, and externally the building is a square, with segmental recesses in its sides. From these and other Romanesque circular churches the development of the Byzantine style was easy. The problem was to obtain the largest area possible under the dome, and this was solved by the use of pendentives. To rest the dome on eight piers or an octagon had been accomplished, and it was next essayed to cover a square by a dome, or on four piers instead of eight. At Sta. Sophia this was done. A hemisphere, whose radius was half the diagonal of the square, the sides of which vertically cut the sphere, was the geometrical solution. The pendentives formed the four corners of the square, and descended to the springing of the vault. By this simple method a square space was roofed by a circular dome, the diameter of which was equal to the diagonal of the square, and great constructional advantages were secured at the same time, as the weight of the dome and its thrust were brought down by the four pendentives to the supporting piers. In the great church of Sta. Sophia, we observe a perfect development of the pendentive dome; the building, to its outer walls, which are rectangular, covers an area of about 70,000sq.ft., equal to many of our cathedrals. To give length to the domical area, two semi-domes are added east and west, of the same diameter, equal to the centre dome, and these latter in turn are extended by smaller semi-domes. By this assemblage of domes considerable apparent scale is given to the building. One large dome equal to the whole area covered by the central and semi-domes would have dwarfed everything by its great size and height. Thus it was reserved for the Byzantines to lift the dome bodily above the walls, and make it a dominating feature in the architecture. St. Mark's, Venice, is an important instance of this fact. The plan, a Greek cross, has five domes, one central over the crossing, and the others over each arm, and the whole area covered is 46,000ft. These domes are semicircular, and have considerably stilted external domes, which emphasise them. Altogether, St. Mark's is an excellent example of the domination of arched forms, and its front of five deeply recessed semicircular portals, and its arched windows above, show to what an extent the arch was carried as an element in external architecture. The well-known church of St. Front, Perigeux, a Greek cross with five domes, resembling St. Mark's, illustrates the same treatment, but the cupolas are pointed.

As Fergusson has shown, the pendentive dome system was thoroughly understood by the Indian builders, who managed to throw the weight of the dome internally, thus counteracting the thrust, and the Jaina architects adopted the Pelasgic or overlapping form of arch, and developed this principle in many ingenious ways. The Hindus rejected the arch constructed of radiating stones, and in every case, constructive as well as decorative, employed the horizontal form. Gateways had a succession of brackets, one overlapping the other, and this bracket arch was common. In covering their spaces, the Hindus first cut off the angles of the square by triangular stones, they next carried this a step farther for larger areas by using three tiers or courses of horizontal stones, the first tier cutting off the corners, the next similarly cutting off the corners of the diagonal square, and the last covering the opening. The area is thus quadrupled, as Fergusson shows. Again, the corner supporting pillars of the square are increased in number to twelve by placing pillars under the intersection of the diagonal with the outer square, and these are sometimes increased by adding external squares on each face of the octagon. By this means a large area was covered by a series of squares with domes making a lozenge-shaped space, and giving a pleasing and varied plan. Fergusson points to St. Stephen's, Walbrook, as a building where this method has been carried out on Classical lines. The dome is carried on eight columns, with four more at the outer angles of the square, and with outer compartments. The Indian plan of roofing has not been followed by Western architects: that it has many beauties and possible applications to modern wants cannot be doubted.

We have alluded to the dome first; but contemporary with it is the Western method of roofing founded on Basilican models, and which culminated in our great Mediæval churches, or as we see it in the cylindrical and pointed vaults of the South of France. The nave and side aisles were covered with round or pointed tunnel vaults, though in the same province the pointed dome-roofed style appears, as at St. Front and at Angoulême. The barrel-vaulted roof was not visible externally—a characteristic which generally prevailed in the vaulted buildings of the Middle Ages. It formed an internal ceiling covered by an outer roof: it had to be resisted by thick walls and buttresses at intervals. When we consider that all arch and vault building arose from the necessity of using small materials in the covering of space, it was economical; but when an outer timber covering became really the roof, its function became more decorative. The introduction of the cross-vault was, however, an important advance, as it enabled the weight and thrust of the vault to be concentrated at four points, and therefore a larger space could be covered. It became in this way a rival to the cupola, and assumed an external expression by the use of buttresses and pinnacles at the points where the diagonal ribs meet. Another architectural feature that seemed to grow with the cross-vault was the gable. But it is chiefly as a method of spanning space that we now refer to the intersecting vault. The triple vaulted aisles of our great cathedrals, and the greater widths spanned by five vaults on the Continent, show how this system adapted itself for the covering of large areas.

The lessons we draw from these older methods of covering space are twofold—constructional and architectural. With our improved facilities and materials we might employ domical construction more than we do. With the exception of the late Mr. Herbert Gribble's concrete cupolas and vault over the church of the Oratory, Brompton, and the introduction of concrete vaults by Mr. W. Emerson in a large Indian building, few instances are within our recollection. The advantage of being able to construct a dome of a thin crust of Portland cement concrete *in situ*, without any thrust, light and strong, does not appear to have encouraged architects. Concrete and iron have been used in flat roofs and floors for many years; but architects seem unwilling, or are too timid, to employ the same materials on a large scale in roofing. Why the domical system of covering space has so little attraction for modern architects, it is difficult to say. We are not subject to earthquakes like many Eastern countries, where domes have always been used, of the horizontal kind, at least; therefore we cannot plead as an excuse its want of stability. The arched forms of spanning space we have spoken of were often the precursors of plan and style—at least, they suggested them;—but it is not so now. Covering space has now become a matter of cheapness and convenience, and the modern invention of the truss and iron girder, the third great system of spanning a void—the other two being the beam and the arch—has superseded these older and more constructional forms. The solid beam or lintel was limited to moderate spans, as it was simply the natural cohesion or tensile strength of stone or marble which had to be depended on; but when the truss was invented, or the "tie," as we see in the ordinary kingpost roof, there was no limit to the covering power. It far excelled the arch or vault, which could only safely span 30 or 40ft. The iron girder or truss in its many forms has made its way in modern architecture, and any shaped plan or space can be spanned by it. It has no influence, like the former methods, on the architecture. This is why our modern "styles" are so characterless. Why insert an arch over a window, if an iron or concrete lintel will do as well? is the reasoning of the modern architect. The arch once influenced style, as we see in the noble Florentine example of Renaissance, the Riccardi Palace, in the Pitti, and in St. Mark's, Venice. Now, it is only introduced as an ornamental form to give variety, in the same manner that we see a domical ceiling of plaster cradled out from a tie-beam roof, a poor travesty of the constructed vault, or a dome serving an inner covering, like those of St. Vitale or St. Mark's or St. Paul's. Why not again make the vault an independent structure and construct it of concrete? The Indian method of overlapping stones we have noticed suggests the possibility of constructing vaults without thrust, and of giving variety to interiors. The modern flat ceiling, with its girders and pillars, has nothing to suggest plan; any shaped room can be covered by it, it does not occupy height; and hence it has superseded other more architectural methods of covering span. The subject is one which deserves more attention from architects. Constructive vault-building appears to be a thing of the past. It is now imitational except for a few churches and important buildings, or is superseded by flat roofs in which cheapness is the main consideration. Timber trusses, boarded or ceiled, are used almost entirely in our churches, because the walls need not be built so thick, and wider spans can be covered, requirements which appeal to the profession generally. There are, however, yet a few of our leading church architects who have revived the vault of masonry, and have, to their credit, done a little to preserve the traditions of vault-building, and to keep that scientific branch of masonry from extinction.

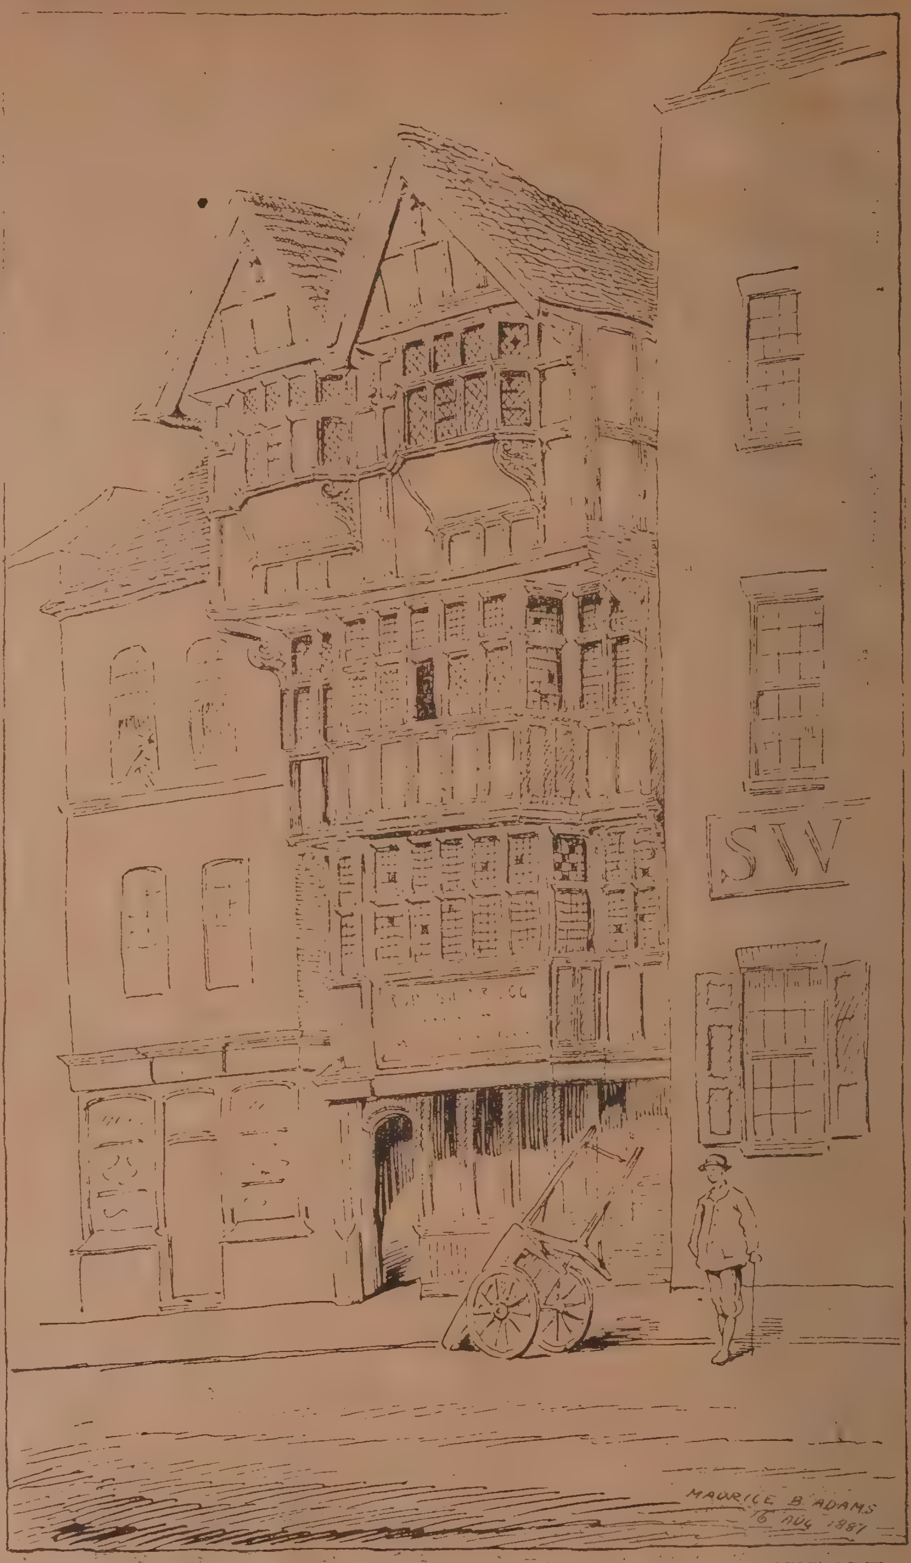
THE ARCHITECTURAL ASSOCIATION EXCURSION, 1895.—II.

[WITH PHOTO-LITHOGRAPHIC AND OTHER ILLUSTRATIONS.]

LAST week we printed several notes with drawings* in connection with this excursion. We now briefly continue our references. Sevenhampton Church, and House hard by, will be visited to-day (Friday), followed by Charlton Abbots and Winchcombe, after which Sudeley Castle is to finish the list for the day. To-morrow (Saturday) will be devoted to the City of Gloucester, which the excursionists will take on their return journey to London. There are two Sevenhamptons in the county of Gloucester, the second being near Swindon, where the Tudor home of the Warnefords, dating from the days of Henry VIII., is situated. The Sevenhampton near Cheltenham, the one to be visited, is best known by the relic of Anglo-Saxon work belonging to the 10th century preserved there, and supposed to have been used as a laver bowl for washing the hands after meals. It is inscribed with classical allusions, and enriched with figure-work in outline. In the village some good Mediæval Domestic work makes the place really interesting and suggestive to the architect. The church is, perhaps, most remarkable for the detached pier of the tower inside the building, necessitated by the fact that the Perpendicular tower is not the full width of the south transept. It was added, of course, long after the church, which was originally erected in the 13th century, and part of the Early English work is still standing in evidence of the antiquity of the fabric, even if, as Petit thought, it is not still older. Charlton Abbots and Whittington are both picturesque villages, chiefly on account of their typical unsophisticated stone-built mullioned dwellings, while at Winchcombe, an old-fashioned market town next seen, there are several picturesque bits, not to mention the more imposing old Jacobite house, of which a sketch figures this week among our lithographs. The church is a spacious specimen of Late Gothic, and has a central tower, erected by Abbot William in the time of Henry VI. The plan of the building is cruciform, and the elaborate groining of the south porch deserves naming. There are a carved oak screen to the chancel and a good Renaissance organ besides candelabra with refined detail. Sudeley Castle, illustrated by us to-day, is thus quaintly described by Leyland, who says:—"The Castle of Sudeley is about a mile from Winchcombe. . . . Boteler Lord Sudeley made this castle à fundamentis, and when it was made it had the price of all the buildinges in those dayes. . . . The Lord Sudeley who builded the castle was a famous man of warre in K. H. 5 and K. H. 6 dayes, and was a admirall (as I have heard) on sea: whereupon it was supposed and spoken, that it was partly builded ex spoliis Gallorum; and some speak of a towre in it called Potmare's Towers, that it should be made of a ransome of his. One thing was to be noted in this castle, that part of the windows of it were glazed with berall. There had been a manor-place at Sudeley before the building of the castle, and the plot is yet seen in Sudeley Parke where it stoode. K. E. IV. bore no good will to the Lord Sudeley, as a man suspected to be at heart K. H. 6 his man. Whereupon by complaints he was attached, and going up to London he looked from the hill to Sudeley, and sayd, *Sudeley Castle, thou art a traytor, not I.* . . . After he mayd an honest declaration, and sould his castle of Sudeley to K. H. 4. Afterwards K. H. 7 gave this castle to his uncle Jasper, Duke of Bedford, or permitted him to have the use of it. Now it goeth to ruine, more pittye." For many years it thus remained in a ruinous condition. Now, however, it has been restored, and it is entirely inhabited, save the banqueting hall, which somewhat resembles the famous one at Kenilworth. It forms three sides of a quadrangle, and is well worth seeing, containing, as it does, an extensive museum of furniture and historical works of art, besides a fine collection of paintings formed by the Dents. Catherine Parr resided at Sudeley with Sir Thomas Seymour, her fourth husband, and at that period part of the castle was altered and renovated. The buildings from 1644 till 1837 remained neglected and uncared for; but on its purchase by Messrs. J. and W. Dent the repairs now seen were put in hand, following somewhat the style of the original buildings. Sir Gilbert Scott restored the chapel, to which there is a curious bell-cot, with a bell dated 1660, and the late J. Berne-Philip, the sculptor, erected a canopied tomb in memory of Queen Katherine, who died here in childbirth.

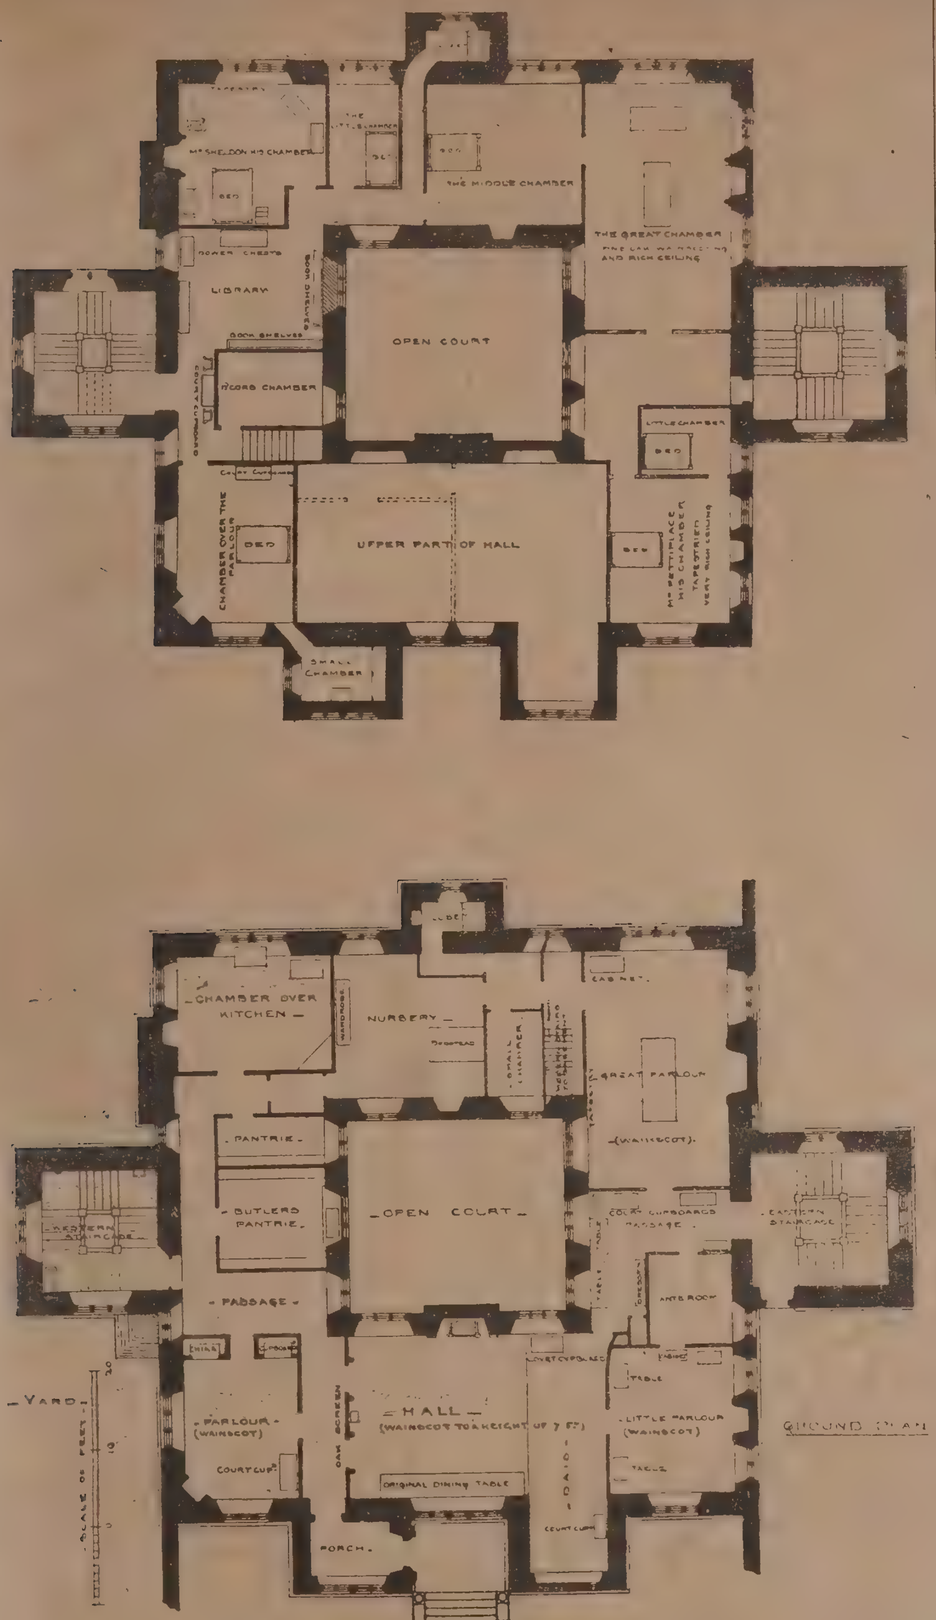
---

* The sketch from Evesham, given last week, and those of Broadway and Winchcombe, in our present issue, are from the pencil of Mr. E. C. Bewlay.



OLD TIMBER HOUSE TEWKESBURY HIGH STREET

To-morrow (Saturday) the excursionists will visit Gloucester, and will be conducted over the cathedral and its precincts by Mr. F. W. Waller, F.R.I.B.A., of Gloucester, from whose "notes" the following particulars are gathered. "The first thing," said Professor Willis, in his lecture read at Gloucester in 1882, "we do know of for certain is, that in the year 1089, thirty-one years only after the dedication of Ealdred's Church, Serlo, the first Norman abbot, began the building of a new church, which was itself dedicated in 1100." To this church of the Great Benedictine Abbey of Gloucester, with all its numerous additions and alterations, the following particulars have reference. The plan of the building is cruciform, and consists of a nave and south transepts, at the intersection of which with the choir rises the great tower; and at intervals round the choir aisles are four small apsidal chapels. At the east end is the Lady-chapel, prior to the erection of which, a fifth chapel, similar in form and dimensions to the other four, existed at the east end. There are also a large chapter-house, a very fine and perfect cloister, and a handsome south porch, with remains also of many of the monastic buildings. The east end of the old church is partly round and partly polygonal—round as regards the outer wall of the main building and the inside and outside of the small chapels in the crypt, but polygonal in the interior walls of the main building in the crypt; whereas on the ground floor of the main building and the chapels, all are polygonal. The whole of the edifice, with the exception of the Lady-chapel and the cloisters, remains, as regards general outline, as it stood in the early part of the 12th century. The nave, with its large circular columns, the slype adjoining the deanery, the N. and S. transepts, with their turrets at the west and east angles, the choir and its aisles and chapels, the chapter-house and Abbot's cloister, although more or less masked by later additions, are all parts of the original building. The crypt extends beneath the choir and the small projecting chapels. One of the chapels is groined and vaulted very beautifully in the style of the latter part of the 13th century with lead poured into the joints of the ribs from above." Mr. Waller asks if the use of lead for this purpose was not uncommon at this date? The crypt walls are 10ft. thick, and the aisle floor is on an average 8ft. below the level of the soil outside. The Norman work there is of two different dates. The entrances to the crypt are from the east side of the S. transept, and from a passage known as the "Abbot's Cloister" next the chapter-house. The vaulting of the nave is of a light porous kind of stone, and was put up during the abbacy of Foliot by the monks themselves (1242) after one of the fires which consumed the wooden roof. The piers still show traces of being more or less calcined. The vaulting shafts are of marble, and the capitals and other enriched parts were formerly painted. The nave floor was originally 10in. lower than at present, and the bases of the large piers stood on square blocks. The nave is 66ft. in height to the under side of the vaulting. The west end was built by Abbot Morwent, and it occupies probably the site of the western façade of the Norman cathedral. It is customary to condemn this work of Morwent's; but Mr. Waller thinks



PLAN OF CHASTLETON HALL.

it exceedingly good of its time (1421-37). The doorways leading to the cloisters in the north aisle are well worthy of observation, particularly that at the east end, which, like the great western doorway of the nave, has four vaulted recesses so constructed as to admit of the doors opening into them.

Thokey was the abbot who caused the body of the murdered King Edward II. to be brought from Berkeley Castle for interment in the cathedral at Gloucester, and the wisdom to secure advantages for the abbey afterwards by means of the offerings made at his tomb is manifest, for these gifts are said to have been so numerous that the costly additions to the buildings made in the 14th and 15th centuries were defrayed by them. Thokey's own particular specimen (if it be his and not Wigmore's), the south aisle façade, is an interesting and grand bit of work, especially the buttresses. The north transept and St. Paul's aisle, by Abbot Horten (1368-73), are cased with Perpendicular panelling on the old Norman walls, and finely vaulted, the entire undertaking being done at the cost of the abbot himself. The screen and stone reading-desk at the entrance to the choir aisle are worth noting. From this desk the monks are said to have discoursed to the pilgrims to Edward II.'s tomb. The south transept, or St. Andrew's aisle, is also the old Norman outline, cased with work—so early as the 14th century as to lead Professor Willis to the expression of an opinion, "that the Perpendicular style might have commenced in this district." If, also, the churches of the city be examined, plenty of Norman, Early English, and "Early Gloucester Perpendicular" can be easily found, but Decorated as it is usually seen, very sparingly; for "Decorated work" never fairly took root in Gloucester. The vaulting is lierne, and without bossess, which are, however, made use of in the later works of the choir and north transept. Mr. Waller directs attention to the "'prentice's bracket" and two doorways in the south wall. The entrance to the crypt is a singular bit of design, repeated to a certain extent in later work in the north transept, in a doorway at the deanery, and in the cloisters also. The choir was cased by Abbots Staunton and Horton (1337-77) in a very ingenious manner, and attention should be given to a feature resulting from the treatment of the ribs of the vaulting, which are very cleverly provided for in the centre of the tower arches. The vaulting is extremely elegant, and the whole of the east end is devoted to one large window filled with painted glass; this window is 72ft. high by 38ft. wide, and contains old glass, supposed to have been painted between 1347 and 1350, when it was put up. It was taken down and re-leaded under the supervision of Mr. Winstone in 1862, and he, fortunately, thus saved the window from restoration. The first cost of the glass, more than 2,000sq.ft., is stated to have been about £140 (!) It is remarked by Mr. Waller that the tracery heads and cusps, as seen from the inside of this window, are not repeated on the outside, a plain transom only crossing the lights; this peculiarity is repeated also in the great west window, and many other windows in this Cathedral. Immediately over the altar, in the groining at the intersection of the ribs, are angels playing on instruments;—this part, if not the whole, of the roof was probably painted and decorated. There are fine sedilia here, and the back part of the old reredos remains, in front of which the modern reredos, inclosing the Feretory, was erected by the Freemasons in 1873. The stalls and misereres remain nearly as of old. The organ screen was erected about 1820, and parts of the old screens were then incorporated. The organ was built by Renatus Harris in 1670; the case is of oak, a fine piece of Renaissance work, and the pipes are beautifully decorated. The choir is 80ft. in height to the underside of the vaulting.

Between the tower arches on the N. and S. sides are two chapels screened off from the transepts, the former by a stone, the latter by a wooden screen. On the back of the stalls of the choir, which forms one side of each chapel, there are traces of painting and monograms. The remains of reredoses are to be seen in both chapels. In the choir aisles the Norman arched windows are filled with Perpendicular tracery with good effect; but on the ground floor outside they are unsightly, the round arch having been cut away, and the soffit plastered. In the windows above they are well managed. The remains of the reredoses in all the chapels are very fine and interesting, especially the "unrestored" ones, and there are some nice specimens of niches and piscinas; also two quadrant-shaped cope chests.

The triforium occupies the space over the ground floor of the aisles, or ambulatory of the choir, and originally extended of a like width round the east end of the Norman church; but at the time when the 14th-century work of the present choir was executed the whole of the old Norman choir was removed to make way for the existing large window, the small east chapel being allowed to remain. This chapel was removed, however, when the present Lady-chapel was erected by Abbot Hanley; but the old Norman altar was preserved. The construction of the whole of the east end of the choir of the building requires much attention, and merits study by the modern architect because of the ingenious way in which the old work was made use of, the constructional difficulties overcome, and the various contrivances for avoiding any interference with the admission of light to the Great Window. The lower portion of the walls of the west end of the Lady-chapel nearest the east window of the choir are parts of the old Norman chapel previously mentioned, and the main walls of the building, erected by Abbots Hanley and Farley, are connected with these, as shown on the ground plan (which we print to-day with Mr. A. J. Dunn's Pugin Studentship drawings), so as to interfere as little as possible with the light of the east window. The plan of the chapel is cruciform, and it is entirely vaulted and beautifully decorated. Two staircases in the N. and S. walls lead to chantry chapels above. The sedilia are exceptionally fine, and there are two excellent old monuments here of Elizabethan and Renaissance work, besides some very good monumental slabs in the floor surrounded by old tiles of great interest.

The south porch is a very elaborate work, highly enriched with niches and canopies, with buttresses at the angles, and a fine doorway, the whole surmounted by a pierced parapet and pinnacles. There is an unfinished room over the vaulting. The side windows are of very peculiar construction, the internal arrangement of the panelling of the side walls being continued to the exterior, and made to form the mullions of the fenestration. The tower was erected during 1450-57 by Abbot Seabroke, who pulled down the old one. The following inscription appears over the western arch:—

> "Hoc quod digestum specularis opusque politum,
> Tullii hæc ex onere Seabroke Abbate jubente."

The tower is 225ft. high to the top of the pinnacles, and the effect is extremely fine. Viewed from the railway as it skirts the city, the tower makes an exceedingly noble pile. From the main cornice upwards, the whole of the stonework is open and composed of what, at a distance, looks like delicate tracery, and mullions, and crocketed pinnacles. There are nine bells in the tower, on one of which is inscribed "Me - fecit - fieri - conventus - Nomine - Petri." It weighs nearly three tons, and is inclosed in a very grand oak framing.

The Cloisters are some of the finest and most perfect in the kingdom. They form a quadrangle and are divided into ten compartments in "each walk." The construction of the outer walls of the E. walk is peculiar as to the arrangement of the buttresses and the projecting shelf of stone connected with the transoms of the windows, which was evidently intended as a protection from the weather, for the lower half of the windows at that time was not glazed. On the south side are the Carols for writing and study, 20 in number, and on the north side the lavatory, with recess for towels, &c. Abbot Horton built the cloisters as far as the chapter-house door, and Abbot Froucester completed them. There is an old well in the cloister garth, and also an old water-tank, not long since discovered. The construction of this tank is singular; it was probably supplied from the mill-stream (now covered up) which ran in old times through the gardens on the N. side of the cathedral.

The chapter-house is a fine Norman room, 72ft. long by 34ft. wide, covered by a plain vaulted roof with large ribs 15ft. apart. The east end is an addition of Perpendicular work. The tiled floor was restored by Minton, who imitated the old encaustic work. The stairs at the S.W. corner, with a stone handrail worked in the newel, led to the old library.

The monuments of leading interest are those to Osric, erected by Abbot Parker (to the founder of the first church in 729 A.D.) during the 16th century; Robert of Normandy, eldest son of the Conqueror, an effigy of oak, time of Henry III.; Foliot, 1243; John de Staunton, in the cloisters opposite chapter-house door; Edward II., Abbot Seabroke's Chapel, and Abbot Parker, the last abbot of Gloucester.

There are many and most interesting remains of the monastic buildings attached to the cathedral, such as the deanery, the infirmary, the little cloisters, and the gateways, and others within the abbey walls. In 1540, this old Benedictine establishment was broken up by Henry VIII. In 1541, a bishop, dean, and prebendaries were appointed, and the cathedral was re-dedicated to the Holy and Undivided Trinity.

COUNTY LUNATIC ASYLUMS.—XXV.

By George H. Bibby, F.R.I.B.A.

PATIENTS' WORKROOMS.

WORKSHOPS for occupation by the patients of asylums differ in several respects from those for the use of sane workpeople, both as regards construction and arrangement. One of the most important matters for consideration is the absolute necessity for means of thorough supervision by the attendants. For this reason the partitions between the various sections may be glazed so that the officials may inspect the patients when at work, and be prepared to interfere when quarrelsome or other patients show a disposition to interfere with their neighbours.

It is, of course, greatly to the interest of all that a large percentage of patients should be persuaded to employ themselves upon such work as they may be found capable of performing, even if the result of such occupation should be found (as is frequently the case) financially unremunerative. Therefore, the workrooms should be very cheerful, spacious, well lighted both by day or night, and the ventilation, warming, fittings, conveniences, and appliances should be fully sufficient for the comfort and well-being of the patients, a considerable number of whom are constantly employed, and spend a large portion of their time in the room, and whose prospects of recovery depend to no little extent upon the adequacy of the provision made for them in the above matters.

The carpenter's shop and any other workrooms where shavings, wood, oil, varnishes, or other combustible materials are used or kept should be placed in an isolated series of buildings, and if for any purpose petroleum or other dangerous oils or spirits are required to be kept in considerable quantities, a detached brick building or shed, &c., with iron doors, should be provided, similar to those generally found in connection with factories and workshops, the owners of which are compelled by the public authorities to adopt such precautions.

All the above named erections should be at least 60ft. or 70ft. from the main buildings, so that if any fire should arise it could easily be localised.

It is undesirable that there should be any coal or coke fire in the carpenter's shop; the glue should be heated either by a gas apparatus, or, better still, a steam pipe from the boiler department.

There should be observed every practicable precaution with the view to prevent dangerous patients from possessing themselves of the sharpened tools, &c., in the carpenter's or other workshops; therefore these should be kept in locked-up receptacles, and the workshop left fastened after working hours.

The upholsterer's shop of an asylum is often of considerable area, and for large institutions may be divided into two or more divisions for purposes of sub-classification, and with the view also of separating patients who may have antipathies and be liable to quarrel. This department is a most useful one, especially for large asylums where, indeed, it cannot be dispensed with; but here, again, there are dangers to be apprehended from the obviously necessary presence of hammers, chisels, and various cutting-tools which are liable to be used by would-be suicides; therefore great precautions are taken in the selection of patients, and care should also be observed that these dangerous tools are not stolen or hidden. Therefore it is desirable that the workrooms should be so constructed that the working patients shall stand, or be seated, according to the nature of their employment, in long lines parallel with the length of the rooms down which the workmasters or attendants can conveniently observe all that is going on. This plan is a far more satisfactory one than if the patients are placed in square, L-shaped, or irregularly-planned rooms, and the fittings and furnishings should be so disposed that there may not be obstacles to a clear view of the area in charge of the attendants, or of the head workmaster or attendant, who, in the larger asylums, goes from ward to ward, and from workroom to workroom, to see that the attendants are performing their duties, and also to ascertain whether or not the patients are fit to continue in the employment given to them, or to advise with and instruct the junior officials.

The number of persons employed upon painters' work is (comparatively) not very large in any asylum. In the year 1893, 43 persons following this trade were admitted to the five London asylums. Many of these, possibly, were quite incapable, by reason of their mental condition, to execute any work; but, on the other hand, no doubt many persons not brought up to the trade might be taught the work with advantage, care being observed not to allow certain classes of them to go up ladders or place themselves in a position where they could easily injure themselves purposely or by accident. The workshop for painters need not be a large apartment; but there might be a shed for stores, under which large articles to be painted could be placed. The work would appear to be sufficiently easy for a much large number of persons to be occupied upon, than is customary in most asylums, considering the enormous amount of painter's work required in connection with repairs and maintenance of the buildings. In many asylums, probably most, the attendants *work with* the patients instead of standing by and watching them (as formerly was usually the case). Nothing could be better calculated to improve the relations of patients to attendants than this plan, and for obvious reasons.

Bricklayers, plumbers, painters, carpenters, joiners, smiths, tinsmiths, gas-fitters, fitters, and other non-patient workmen are employed upon the staff of asylums, and more or less their engagements are of a permanent nature. The men so engaged work to some extent with the assistance of the patients, but certainly not in many asylums so much as could be desired, or as is the case with tailors, shoemakers, upholsterers, and others.

The plumbers', smiths', and engineers' workshops might very conveniently be situated near to the boilers and engineer's rooms and the asylum fire-engine station. In a large asylum there is necessarily always a certain amount of engine-work, repairs to ventilating and heating apparatus, to cisterns and tanks, machinery in the laundries and cooking apparatus, and to the water supply system, hydrants, gas and electric-light fittings, &c., and it is desirable that such works as these and of a kindred nature should be brought conveniently near to each other in the workshop arrangements; while the tailors', shoemakers', and upholsterers' work-rooms may be arranged for under a second division (connected with the main buildings by an inclosed corridor, or, at all events, a covered way).

In all large asylums there should be one room for use as a printer's office, and supplied with a printing-press. This will enable the asylum authorities to produce programmes for concerts and balls, asylum forms, stores orders, reports, and perhaps a small weekly or fortnightly asylum magazine, to which both attendants and patients in some asylums contribute; and in connection with the printing office there might well be provided a small room for repairing and binding library and other asylum books.

In conjunction with the before-mentioned work-rooms, there must be a few store-rooms, for the purpose of containing spare furniture and articles under repair, also for the storage of raw and manufactured materials. It would be preferable that these store-places should be formed in a series of moderately sized apartments rather than in large rooms, so that there may be favourable opportunities of temporarily increasing the number of work-rooms and the variety of work (should occasion require that special employment must be provided for patients who cannot successfully be occupied in the ordinary asylum work-rooms).

It is necessary that the previous occupation (if any) and the condition in life of patients in asylums be carefully considered, prior to settling the occupation they are best fitted for, and the employment most likely to conduce to their mental recovery. It does not necessarily follow that a patient should always work at the trade he was brought up to, especially if such business be not of a healthy character, and having in view also, possibly, that that occupation may have been one for which he was partially or wholly unfitted, mentally or physically.

Therefore, if the store and spare rooms included in the workshop buildings be divided, these could frequently, during pressure of space, be utilised for such work as may be contrived to occupy advantageously those patients who, although pauper inmates, have yet in happier times occupied a fairly good position as professional men, such as accountants, authors, bankers' clerks, medical men, draughtsmen, journalists, and surveyors, all of which classes, amongst others, are to be found occasionally in county lunatic asylums, and the employment of whom upon such work as the scrubbing of the ward floors, or upon the various rough trades for which they are physically unsuitable, would not be likely to promote any chances of mental recovery that they may possess.

The nature of the work to be provided for the patients necessarily differs very much in country and town asylums, and has some relation to the staple trades carried on in the district from which the patients are drawn. I have, in a former paper, referred to the overcrowding and other disadvantages of some of the asylums in Ireland; but in one asylum there, at least, the workshop department appears to be very well managed, and possibly this may be due in some degree to the convenience and sufficiency of the apartments provided for the purpose. The following table, giving the exact number of patients employed in an asylum of very moderate extent (and therefore unfavourably placed for comparison with many of our modern asylums as regards facilities for useful employment) shows that the Mullingar Asylum is a very busy centre of industry:—

Occupation.	Males.	Females.
Assisting attendants in the wards	37	49
As garden labourers	17	—
As farm servants	107	1
As storekeeper	1	—
As messengers	3	—
As stokers	2	—
As tailors	8	—
As shoemakers	8	—
As upholsterers	19 (average)	—
As painters	5	—
As joiners	5	—
As plumber	1	—
As masons	3	—
As slaters	2	—
In the kitchen	5	2
In the laundry	7	40
In officers' quarters	2	1
At needlework	—	73
At knitting	—	23
Stablemen	2	—
Other employments (slaughter-house, poultry yard, hair-picking, &c.)	94	16
Total employed	328	205

It therefore appears that, out of the 622 patients resident in Mullingar Asylum, no less than 328 men and 205 women are employed in one way or another. *Only ten refused to work*, while 54 were prevented by mental and 25 by bodily causes from useful occupation.

The large number of patients employed in this asylum has excited the surprise of a distinguished English superintendent, and, indeed, a return such as that above given compares favourably with the industrial work done in other asylums in the United Kingdom, and it does not appear probable that an asylum architect will be called upon in the near future to provide in his plans for a larger proportion of working patients.

In the summer months at this asylum a large number of the patients have been brought out of the wards or workrooms, and have sat or worked in two large tents pitched in front of the asylum, and a striking feature of this asylum is the very large proportion of usefully-employed patients, the good character of the staff, the excellent discipline, the absence of all appearance of restraint or unnecessary restriction, and the general contentment prevailing throughout the asylum—a condition of things which would be difficult of attainment in an indifferently-planned or inconveniently-arranged asylum.

The asylum architect in arranging his plans for an asylum of such moderate size as that at Mullingar, where out of 622 patients no less than 533 were employed, would do well to provide workrooms, &c., of much greater proportionate area than for asylums of the London County type, where the numbers of patients who can be induced to work is so much less in comparison, as appears from the following table which gives the numbers in the *five* asylums for the County of London at a recent period:—

MALES.	
Total employed	2,270
Unemployed	864
Sick, old, or infirm	916
Absent on trial	9
Total in asylums	4,059

FEMALES	
Total employed	3,113
Unemployed	1,889
Sick, old, or infirm	1,107
Absent on trial	12
Total in asylums	6,121

In these asylums the proportion of working patients is greatly below those who are employed at Mullingar, and this does not entirely arise from the fact that many of the patients at the latter asylums are engaged upon farm work, &c., for the proportion of land to the patients is said to be insufficient, so much so that the Mullingar Asylum is obliged to obtain contracts for milk, and the authorities are desirous of obtaining a further 100 acres for this reason, and also in the hope of obtaining for their patients increased healthy occupation, and more extended exercise and recreation.

There can be no doubt that a well-considered plan for the asylum workrooms (which are really schools as well) is of very great importance. The patients and attendants in asylums perform their work under vastly different circumstances to those found in ordinary factories and workshops, and when I find in the Mullingar Asylum that eight patients were employed as *shoemakers*, and could make 743 pairs of boots (an average of 93 pairs per man per annum), and do all the repairing for 622 patients (and for their attendants), I am led to compare these figures with those for the *four* London Asylums (excluding Claybury) when the total number of patients exceeded 8,000, and where 41 shoemaker-patients made 1,572 pairs of boots and shoes, or only about 38 pairs per man per annum.

These four London asylums, therefore, employ only one shoemaker-patient to each 195 patients, instead of one to 77 as at Mullingar, and as these patients do considerably less than half the work of the Mullingar shoemaker patients, there would appear to have been a loss at the rate of about 6,000 pairs of boots per annum to the London ratepayers. This must be attributed either to a worse mental or bodily condition of the London patients (as compared with those at Mullingar), an inferior system of management of all the London asylums, which appears to be highly improbable, or to defective arrangements or overcrowding of the workshops of the London asylums, and probably other trades would show similar results.

Therefore, while it is most advisable that the amusements of the patients, on the one hand, should receive the utmost attention by the asylum officials, and that suitable buildings for recreative purposes should be provided for by the asylum architect, on the other hand it is most necessary that the workshop buildings should be fully adequate to the purpose of giving the patients that employment and instruction in technical matters so likely to conduce to their well-being, not only while they are in the asylum, but when those that are cured are returned to their homes and families. Therefore, the workshops should be well lighted, both naturally and artificially, and be well fitted, warmed, and ventilated, and be treated by all concerned as schools as well as workshops.

◆

THE CANARY ISLES: STRAY NOTES DURING A RECENT VISIT.

THE archipelago consists of seven islands, the nearest of which (Fuerteventura) is about 74 miles from St. Juby, on the West African Coast. Fuerteventura is the largest of the group, and somewhere about 62 miles long by 19 miles wide. Like Morocco, on the main land, almost within sight, it has no roads, and one has to get about as best he may, on camels or donkey back. It is a barren, sandy, uninteresting place, the highest hill, known as Orejas de Asno (Ass's Ears), being about 3,000ft. high. In the rather curious old church at Maria de Betancuria, the standard carried by the Spanish conquerors in the 15th century is shown, still in fairly good condition.

Next in size is Teneriffe, which is 52 miles, or thereabouts, by 31 miles. Upon it towers the well-known peak, 12,192ft. high (Mont Blanc is 3,592ft. higher), its top, even when we saw it (in July of this year), clothed with a mantle of snow. It has a small crater on its summit 100ft. deep by three times that size in diameter. Out of this a slight sulphurous vapour almost continuously arises. From the top of this mountain, on a clear day, a bird's-eye view of the whole of the islands may be obtained. Grand Canary is 34 miles by 30 miles, and Lanzarote 36 miles by 14. La Palma, the most beautiful of all, is 29 miles long by 17 wide; and Hierro, the most western one, is 18 miles by 13. Gomera is slightly smaller (15 miles by 13). Before the discovery of America, Hierro was supposed to be the end of the world. Its coast is steep and dangerous. Near it, another and eighth island, known as Antilla, was supposed to exist in ancient times. So strong was this belief, that, in the early part of the 16th century, Portugal ceded it, by treaty, to Spain, making reference to it in the said document as the Isla non trubada (*i.e.*, the Island not found).

The Canaries are six days distant from England. We went out by the Castle line *Harlech Castle*, and came home by a Union steamer, *Guelph*. It is easier to get there than to come away again. This is especially the experience of those who hold a return ticket issued by any one line. All the steamers that call come from long distances, and hence the time of their arrival is somewhat indefinite. For instance, when we got to Las Palmas (the name is pronounced as spelt, and the town is the capital of Grand Canary), we found the homeward-bound steamer for England, that was due two days after our arrival, had in reality sailed for Southampton the day before we got there!

Las Palmas is an Eastern-looking town, its white, flat-roofed houses picturesquely situated on a slope, backed by sharply-defined hills. The general grouping, however, is rather spoilt by the towers and upper portions of the 16th-century cathedral, which are in every way as incongruous to the surroundings as is Brigham Young's flat-domed tabernacle at Salt Lake City, in Utah, U.S.A. Las Palmas has a population of about 21,000, and is connected with the port (Puerto de la Lux) by steam trams (2d. all the way). This distance between the two places, around the sandy bay, is about four miles. The tramcars, which, like those at Chicago, run three together, were made at the Falcon Engine and Car Works, Loughborough. The engines are German. There is also a small engine at Santa Crux in Teneriffe (53 miles away), which pulls the freight-laden waggons from the mole into the town. The islands have no other aids to locomotion by steam.

Las Palmas is now one of the principal coaling stations of the world. Passengers are landed on the unfinished mole, which already runs out to sea 1,450 yards. Commencing at a depth of six fathoms, the divers (who are Spanish) are now working at quite double this depth, and the pier will extend 200 yards further out. A counter-mole also is already started. The work has been in hand fully eight years, and it is expected to be completed in about 1897. Messrs. Swanston and Co., of London, are the contractors for the work with the Spanish Government, and Mr. Bigglestone, of Hayle, Cornwall, is the resident and directing engineer. The entire cost is estimated at upwards of £300,000. The whole of the work is in concrete, made of lava, hydraulic lime, Marseilles cement, and picon (volcanic cinder), ground fine. The breakwater is not built up perpendicularly, but leans at an angle of 35° in towards the shore. The blocks used weigh 35, 22, 17, and 12 tons each respectively, and are lifted by a 50-ton Titan crane, built by Appleby, of London.

A remarkable feature in Islata (Las Palmas' port) are the lava flows, of which there are distinctly four—one over the other. The lower one is some 40ft. thick. On this is 3ft. of scoriæ, and above a slight depth of soil; then comes a second lava flow of 25ft., a third of 10ft., and yet another of 4ft., above and between each of which is about the same quantity of soil and scoriæ. Geologists consider there must have been at least a thousand years between each of these four eruptions.

About half-way between the port and Las Palmas, and close by the sea, is the Hotel Metropole—an excellent English hotel, built, in the main, of red brick brought from England. This building is now being considerably enlarged. Hard by is the English church, erected two years or so ago from the designs of Mr. Somers Clarke, F.S.A., architect, of Westminster. It is to be presumed that Mr. Clarke adapted his design to the requirements of the country. It is not quite what we should call an ideal English church at home. The Santa Catalina Hotel, a large Oriental-American-looking caravansary, situated between the church and the town, was also, we believe, designed by Mr. Clarke. There is a fair amount of building going on at, and about, Las Palmas, principally of rough stone and bricks (the latter are very bad), plastered over. Excellent limestone, however, is obtainable, and used on the island. The best quarries we saw appeared to be at Jinamar, a village on the main road from Las Palmas to Telde, lying in a valley below the now extinct volcano known as the Gran Caldera. This road, by the way, winds around the bay, which is even more lovely, one is inclined to think, than that of Naples, and passes (near Jinamar) through a tunnel several hundred yards long. Its borings are roughly, very roughly, quarried through the solid rock, just as the Box tunnel on the G.W.R. near Bath, as well as some other English tunnels, are. Outside Las Palmas, on this road, perched upon the steep rock side, is the English cemetery. It is surrounded, as most Southern cemeteries are, by a high wall, and the difficulty of slope is got over by steps, thus making the burying-place into a series of terraces. The flower-grown burial-ground contains some marble and other memorials of the usual monumental kind, by Gawen, of Regent-street, W., and other English statuaries. When we were there the body of a young Englishman, who had died the previous day on board an African West Coast steamer, stood on trestles at the lych-gate awaiting the result of the Vice-Consul's search to find an English-speaking clergyman to perform the last rites. The coffin was wedge-shaped, tapering, both on plan and elevation, towards the feet. The line of the lid was that of three sides of an octagon. All the coffins we saw on the island were of similar construction.

Not very far off, and on a plateau just above the sea, is the general cemetery for Las Palmas. It also is walled around, and its smallness at once strikes the visitor. There are a few good monuments; two (one of them has just been erected by a Carrara firm) must have had many thousands of pounds expended upon them. We have seldom seen more costly modern sepulchral erections, not even in the United States, where more money is spent upon such work than it is the general custom to do amongst ourselves. The large majority of the "well-to-do" are buried in catacombs—shelves that go around two sides of this tiny God's Acre. A very dreadful custom exists here of not allowing the remains of any of the humbler class to stay in the ground more than two years. Further, those remains incased in the catacombs are also as unceremoniously turned out after the same time, if their surviving relatives do not annually pay a goodly rental. The bones or bodies, as the case may be, are thrown into a heap in one secluded corner, and there, uncared-for and unrecognisable, we saw what remained of the comparatively recent population of the place, now nought but a ghastly heap of skulls, limb-bones, ribs, and vertebræ, as well as a few only semi-decomposed bodies. It was a sight, once seen, never to be forgotten!

On the sea-shore, in front of the Triana, the main street at Las Palmas, some half-a-dozen schooners are on the stocks. They are about the size of Brixham fishing-boats. An octagonal tower is being erected to one of the churches, and workmen are engaged on the south-west tower of the cathedral. In the latter we were shown a splendid *porta-paz* in silver-gilt, by Benvenuto Cellini (about A.D. 1550). Whilst speaking of metal-work, it may be remarked that especially interesting features in many churches on these islands are the ancient shrines and altars of embossed silver. The latter consist of a framework of pierced wood, cut to the outline of the ornamentation it is intended to put upon it. This is afterwards covered with hammered and raised silver repoussé work, a treatment that has at once an excellent and most ornate effect.

All the churches we saw on the islands were, as a rule, small, most of them consisting simply of a single nave. Instead of an east window, the altars generally go up to the roof, and are of richly-carved wood, their unquestioned dignity helped by colour and gold. The oldest church on the island of Grand Canary is that of San Antonio Abad, situated quite near to the cathedral, and in certainly the lowest part of the city. It was here that Columbus, in the latter part of the 15th century, heard Mass on the morning he finally sailed away on that eventful voyage which led to the discovery of America. It is a small, thick-walled edifice, lit only by a wee west window high aloft, and by a north and a south one, also high up above the sanctuary. These two latter windows have balconies projecting from their interior bases. The altar-rails are high, and of rudely-wrought iron, and look as old as the church itself. The east end is one mass of carved and gilded woodwork, a trifle too loud in decoration for English eyes, perhaps. The floor is of dark grey limestone; there are north and south altars; the walls generally are hung with warm-coloured drapery. It has an open-timbered roof, and here, as in many other churches, the beams are uniquely treated by the introduction of inlaid or painted (the edifices were generally too dark to be quite sure which) ornament of an Arabesque character upon their lower face. On the northern side of the west end is the inscription: EN ESTO SANTO LUGAR ORO COLON, 1492—1892. Colon is the Spanish rendering of the name Columbus.

Later on, in our visit at San Sebastian, in the Isle of Gomera, situated about a score miles from Teneriffe, we were shown a church containing an interesting oil-painting representing the repulse of the Dutch from that harbour in 1599. Here, too, Columbus attended Mass whilst his three ships, the *Santa Maria*, *Nina*, and *Pinta*, took in water and provisions. An old house, in which, tradition says, he slept, was also shown us. No one walks in the Grand Canary; visitors are driven rapidly and economically about in light covered dogcarts, known locally as tantaras. These are drawn by one, two, or three little horses, who seem to delight in taking the steepest hill at a hard gallop. The splendid tropical foliage, perhaps, strikes the visitor the most in the many beautiful drives that may be taken at every hand. The thousands of acres of fruitful bananas, the tall date palms, the vineyards, and fields of sugar-cane are very impressive. The hedgerows of red geraniums and of the cruel prickly pear and the tall and graceful aloe are seen almost everywhere, whilst many of the roads are continuously planted with the eucalyptus tree, affording a most refreshing shade.

A large number of the inhabitants live in caves, natural formations in the sides of the mountains, which are probably air-holes, when the crust cooled down, in the long-ago days. These dwellings seem fairly comfortable inside, and many of their occupants continue to make pottery just as the Canarios made it a thousand years ago. No potter's wheel is used, and the designs are much as are those we have seen in Morocco. The jars in general use for holding water are of good outline, and as the women carry everything on their heads (save their babies, who straddle on their hips), the bare-footed damsels, wearing white Moorish-looking headdresses, and deftly balancing these pitchers upon their crowns, look very pretty indeed. Water is obtained from metal hydrants in Las Palmas, and the women and girls, with accompanying barely-dressed children—some of the little ones we saw were altogether nude—bearing their cave-made pots and pans, and crowding together around the taps, make the most charming groups imaginable. It is much to be feared, however, that in the near future these interesting locally-made ewers will become almost a thing of the past. All the oil for lighting purposes used upon the islands seems to come from the United States. It arrives in tins, 1ft. 6in. by 1ft. by 1ft., or thereabouts. These tins, when emptied of their contents, being lighter and holding more water than the earthen vessels, are rapidly finding favour with the water fetchers, and are steadily and surely outing out the crocks. Atalaya, in Grand Canary, is perhaps the largest collection of troglodyte dwellings in the islands. The clay for pottery, which their inhabitants fashion on a round stone, is dug in the immediate neighbourhood. These cave-dwellers seem quite distinct from the Spanish-like inhabitants of the towns, and rarely, if ever, intermarry with them.

In driving to Telde, some fine examples of the *Euphorbia Canariensis* are passed. This is a wonderful tree, indigenous to the Canaries, having leaves (if they may be so called) like New York policemen's clubs, and strong caustic for sap. Curiously, it grows nowhere save where its roots can be in actual contact with the solid lava Telde itself is a Syriac-looking city, of something like 10,000 inhabitants. The church in the main square has a south-west tower, in the midst of whose parapets are hung four large bells. On climbing the tumble-down steps, and reaching the summit of this campanile, we found two of the bells old, and the others bearing the names of Messrs. John Warner and Sons, of London. The western doors were painted a dark red—a common practice on the island—and studded with bronze nobs, 3in. in diameter. They have a couple of very curious knockers, and a quaintly conceived escutcheon to the keyhole, all in the same metal. Artistic bronzework upon the outsides of the church doors is not at all unfrequent. The church contains, amongst other things worth examining, nine handsome Venetian glass chandeliers and a curious revolving choir-lectern, having a grand old music-book upon it. We remember seeing just such another volume as this in the summer of 1889 in an old church at Ceuta, a Spanish penal settlement on the north coast of Africa. This lectern is in the north-east chapel, which has an exquisite octagonal roof of carved wood, which looked like teak. The baptistry at the south-west end is divided off from the south aisle by an effective screen of painted wood. It consists simply of parallel transoms running pretty close over each other, filled in between with turned mullions. The effect is striking, considering the simplicity of the design.

HARRY HEMS.

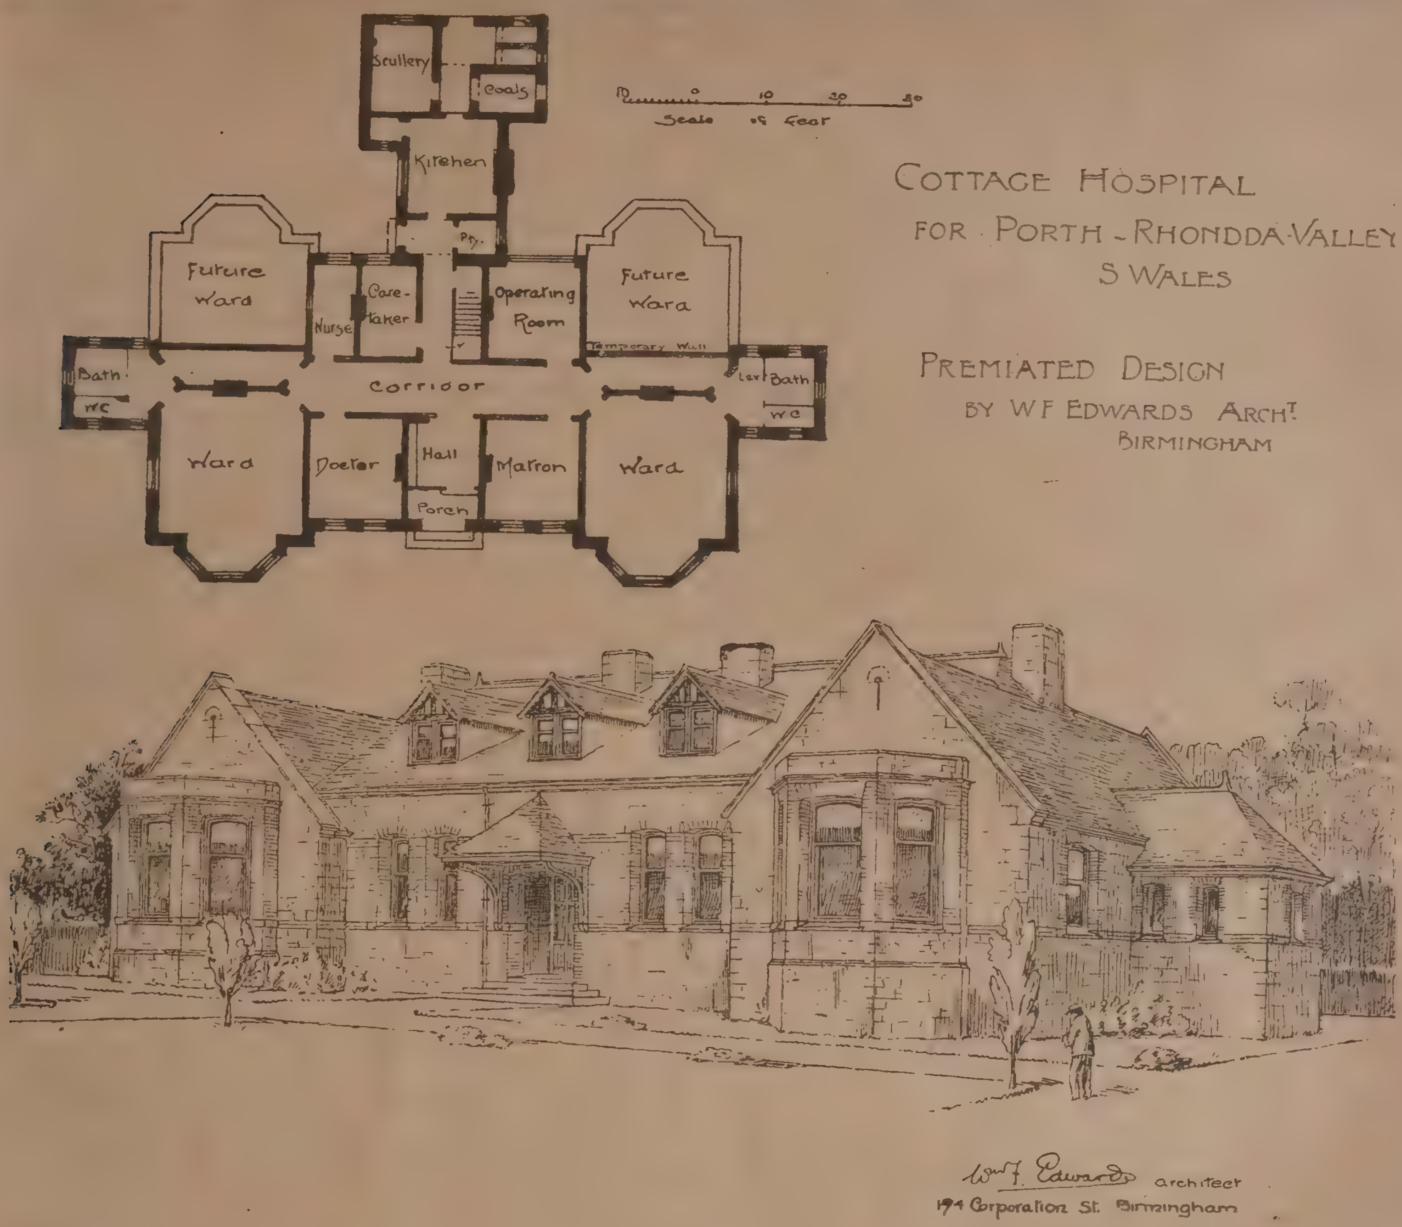
◆

LONDON BOARD SCHOOL BUILDINGS.

THE annual report of the Works Committee of the School Board for London, just issued, describes the work done in the matter of purchasing sites for schools, erecting school buildings, and preparing generally for the reception of children of school age.

During the year ended March 25 last the Board were engaged in the purchase of interests in 55 sites. The cost of these interests was £82,265, the surveyors' fees being £980. The value of all the sites purchased or agreed to be purchased previous to March, 1894, was £2,903,207, and the costs £406,601. Thus the total cost of the sites purchased up to the end of the financial year under review was £2,985,472, and the fees £407,581. The cost of the sites for 294 schools up to September, 1894, was £6 15s. 3d. per child. The total number of permanent schools which had been erected and opened up to Lady-day, 1894, was 397. During the year under review nine additional schools and 28 enlargements were opened. The total amount of loans which the Education Departments authorised the Board to incur on account of the nine new schools and sites was £170,417, and on account of the 28 enlargements and sites £301,555. The average cost per head of the 294 school buildings was £12 2s. 3d., and furniture and fittings 10s. 6d. Tenders have been accepted during the year for erecting eight new schools, providing accommodation for 7,447 children, and 22 enlargements of schools, including two new junior mixed schools and one senior mixed, providing accommodation for 7,102 children. Each of the eight schools will be provided with halls, and the tenders include the provision of centres for cookery, laundry, or manual training centres, and in many cases a drawing-class room. With regard to the enlargements, opportunity is taken to improve the existing schools so as to make them thoroughly efficient. Tenders have also been accepted for erecting 19 cookery centres, 29 laundry centres, 30 manual training centres, adapting two houses for housewifery centres, erecting three schools for special instruction, and adapting a house for the same purpose, erecting a deaf centre, providing the necessary rooms for the teaching of the upper standards at four existing schools, erecting divisional offices for two divisions, adapting the Drury-lane school for the purposes of a day industrial school, inclosing, levelling, draining, and tarpaving additional land acquired in connection with 15 existing schools, carrying out drainage and sanitary works to 34 schools, providing hot-water apparatus at many schools where the heating by open fireplaces was insufficient, and carrying out various structural alterations and improvements to schools. In addition to those schools and enlargements for which tenders have been accepted, finished plans of the enlargements of ten other schools have been approved. Further progress has been made in the improvement of drains and sanitary arrangements generally in the schools.

General Moberly, as the chairman of the committee, adds, that the standard of education and accommodation during the past five years has been greatly raised, and the committee have endeavoured to arrange the schools in accordance with it. Great difficulties have been met with in carrying out much-needed improvements to a very large number of old schools to bring them up to modern requirements; and this work has, as a rule, been done in connection with the enlargement of the schools. During the last three years 34 new schools have been opened, accommodating 32,887 children, and 60 enlargements of previously existing schools have added further accommodation for 19,479 children. General Moberly points out that far more time and labour are spent both in preparing plans and in carrying out the work of enlarging an old school than in designing or building a new school. On the subject of sanitary arrangements, the chairman of the committee observes that some years ago there was a suspicion that the drainage works in connection with some of the schools had been very inefficiently executed; but glaring defects came to light, and action was taken to set things right. In deference to modern requirements the system of drainage of 15 or 20 years ago has been removed in 79 schools, and newer methods have



been introduced; and a similar improvement is being carried out in 36 other schools.

The committee's report further states that the system of carrying out repairs to school buildings by workmen employed direct by the Board is being continued in nine of the eighteen districts, and at the date of the report 79 workmen were so employed. The wages paid to these workmen are the same as are required by the Board to be paid by contractors to the workmen employed by them. On March 25 last the following was the amount of school accommodation in course of provision: Ten schools were in course of erection, providing accommodation for 9,622 children, and 24 enlargements, providing accommodation for 7,562 children; 26 additional sites for new schools had been or were being purchased, the schools to be erected on which would provide 22,202 places; 25 sites had been scheduled, the schools on which would provide 21,800 places; 34 enlargements had been sanctioned, providing 11,919 additional places; and the Education Department had also sanctioned the provision of sites in six districts, the schools upon which would provide for 4,000 children.

COTTAGE HOSPITAL, PORTH.

WE give above an illustration of this hospital, for which Mr. W. F. Edwards, of Birmingham, was awarded the first premium. On the right-hand side of the entrance are the matron's room and ward for four beds; on the left-hand side, doctor's room and a similar ward. Both these wards are connected by a central corridor, on the other side of which are rooms for the nurses, caretaker, and for operations, and also the entrance to the kitchens, which form a projecting central block at the rear. It was proposed to build the walls of local stone with brick dressings, and plaster internally with adamant plaster. The estimated cost was £2,000.

THE BRITISH INSTITUTE OF PUBLIC HEALTH.

THE annual congress of the British Institute of Public Health was held on Friday, Saturday, Monday, and Tuesday at Hymer's College, Hull. About 300 delegates were present. At the opening meeting the Mayor and the Sheriff of Hull welcomed the members of the congress, and Professor W. R. Smith, President of the Institute, acknowledged the reception. The meetings were then divided into four sections. In the municipal and Parliamentary section Sir Albert Rollit, M.P., presided, and in his opening address spoke favourably of the advance of municipalisation. The local institutions should be jealously guarded against the present tendency downwards in its limitations, and every effort made to relieve the congestion of Parliament. He pleaded for a devolution to local authorities of all local affairs, subject only to a minimum of central control for general purposes, a control which should be judicial rather than executive. Public water supplies for rural districts, and public washhouses in relation to the sanitary condition of the homes of the working classes, were among the subjects discussed in this section, and in that of chemistry the bacteriology of waters was discussed. The sanitary engineering and building construction section was presided over by Mr. W. Spinks, lecturer on sanitary engineering, Yorkshire College, Leeds. A paper was read by Mr. G. J. ~~G.~~ Broom, borough surveyor of St. Helen's, dealing with sanitary arrangements. A long discussion followed, and a resolution was ultimately adopted expressing the opinion that it was very desirable that a water-carrying system should be adopted in towns where a water service was laid on, also that there should be a *minimum* flush of three gallons, and that all water for sanitary purposes should be free of charge. "Dust and Refuse Disposal" was the subject of a paper read by Mr. S. J. Beaman, Warrington, in which he advocated the burning of refuse. He believed that it would not long be tolerated that refuse should be destroyed without its being requisitioned to serve some public and beneficial purpose —such as the generation of steam for a variety of purposes. Another question considered was the provision of cremation by urban authorities. This question was opened by Sir H. D. Littlejohn, who said the question was one of the utmost importance, for it would be for the public good that the disposal of the dead should be under the control of urban authorities, just as much as the control of gas and water. The present method of burial was injurious, polluting as it did the soil, and frequently contaminating the water supply. Dr. Holder, of Hull, strongly supported the establishment of crematoria, and stated that, as a member of the Hull Town Council, he had carried a motion to provide a crematorium, and a plot of land had already been provided on which to erect the building. On the motion of Sir H. D. Littlejohn, it was unanimously resolved: "First, that in the opinion of this congress it is essential, in the interest of the public health, that all municipal and local authorities should be empowered to provide crematoria, and that a copy of this resolution be sent to the Local Government Board. Secondly, that a petition be presented to Parliament, signed by the president on behalf of the congress, in support of the Bill about to be presented to Parliament to confer power upon municipal authorities to provide crematoria." In the preventive medicine section, Professor W. R. Smith opened a discussion on the influence of schools upon diphtheria. During the subsequent discussion, one member said there was more danger from "jerry" built houses than from schools. The question of the housing of the working classes was introduced by Mr. J. C. Wood, of Sunderland, who spoke of the wholesale manner in which insanitary houses had been closed in Sunderland by the sanitary authority. This, he said, was all back-to-back property, and all refuse had to be brought through the houses, in some cases the bedrooms having to be passed through, and occasionally the bed had to be removed before the refuse could be got through the room. The subject of the definition of a sewer was discussed in the engineering section, and the following resolution was adopted:—"That this section is of opinion that the definition of a sewer given in the Public Health Act should be amended, and that a public sewer should be defined as that laid down by a sanitary authority in a public thoroughfare, or taken in charge by a sanitary authority." A further resolution was carried in this section to the effect that it was desirable that every house in a watering-place where lodgers were accommodated should undergo a survey by the sanitary authority, and that a certificate of fitness should be compulsory. It was also resolved: "That all plans and specifications for new schools, or for alteration or enlargement of existing schools, should be submitted to the medical officer of health for the district in which the school is to be erected or altered, for his approval and criticism, especially with reference to the provision for drainage and sanitary accommodation, and that the Education Department should require a certificate from the medical officer of health that he approves of the drainage and sanitary accommodation of the said schools before passing the same; and also that the annual education grants should be made dependent on a certificate from the medical officer of health that Article 85 (a) of the Code is satisfactorily complied with as regards each school in his district."

BIRMINGHAM ARCHITECTURAL ASSOCIATION.

SHOWERY weather somewhat interfered with the members of this association, who went sketching into Shropshire on Friday, Aug. 2, until the following Tuesday, but a good deal of work was done. The party made the Feathers Hotel, which is so well known to visitors to this interesting town, their headquarters, and drove, on the first day, to Whitton Court, a delightful Elizabethan house, which has been very carefully repaired during the last few years by Mr. J. A. Cossins, of Birmingham. The house abounds in panelled rooms and old furniture, and is situated in a charming garden full of flowers. Miss Mills, the owner, kindly entertained the visitors with luncheon, and gave free run of the house. The small church adjoining has lately undergone repair at the hands of Mr. Aston Webb, who rebuilt the chancel; and the church of Burford, some three miles distant, contains a great deal of the same architect's work, which is of considerable interest and taste, but to a great extent has wiped out the character of the old church. On the north wall of the chancel is the noted triptych. Sunday morning was devoted to Ludlow Church and Castle; the afternoon to Mr. Norman Shaw's new church at Richards Castle, about four miles away. The site falls to the south, and advantage has been taken of this to arrange the parts so as to form a most charming group, the tower at the south-west being detached but for a small connecting lobby, and is the principal entrance. Many characteristics have been adopted of the old church, which stands about a mile away. One of its features is the detached tower at the east end, and it is a subject for congratulation that care is being taken of the old structure, so as to preserve it from untimely decay and destruction.

Stokesay Castle, gateway, and church, so full of interest and delight to all students of architecture, occupied practically the whole of Monday, and well repaid the time spent there, Bromfield being taken late in the afternoon on the return drive to Ludlow. Here is a stone-and-timber gateway to the churchyard, the upper part of which, until the present vacation, has been used as the village school, only lately being condemned by the Education Department. This church has undergone restoration by Mr. Fowler, of Durham, but still retains much of its interest.

On Tuesday the programme was altered, the day being spent in Ludlow itself, and the evening brought to a close one of those excursions which not only inspires reverence for the past art of our native land, but instils into the student's mind that good feeling towards our professional brethren which is happily on the increase, through the agency of the various architectural associations.

Chas. E. Bateman.

OBITUARY.

Mr. Richard Morris Hunt, of New York, one of the best known of American architects, died at New York on July 31st in his 67th year. He was the son of the late Jonathan Hunt, Member of Congress, and was born at Brattleborough, Vermont, Oct. 31, 1828. In 1843, at the age of 15, he was brought by his mother to Switzerland, and entered a school at Geneva, commencing the study of architecture with Samuel Darier. From Geneva he went to Paris, and studied under Hector Lefuel, entering the Ecole des Beaux-Arts in 1845. On leaving the Ecole he travelled through Europe, Asia Minor, and Egypt, and on his return to Paris in 1854 he received from the French Government the appointment of Inspecteur aux Travaux on the new buildings uniting the Tuileries to the Louvre. His master, Lefuel, having, during his absence, succeeded Visconti as architect, he was put in charge of the Pavillon de Bibliothèque, opposite the Palais Royal, and made, under Lefuel, all the studies and full-size drawings for that Pavilion. Hunt returned to America in 1855—at the age of 27—and spent about six months in assisting the late Thomas U. Walter at the Capitol of Washington. He then, at New York, commenced the practice of his profession, and obtained a large and lucrative connection, one of his chief works being the Vanderbilt mansion on Fifth-avenue, New York. Other of his executed designs are the pedestal to Bartholdi's colossal Statue of Liberty in New York Harbour, the hospital in Third-avenue, the Marquand residence, and the *Tribune* building, all in New York; Mr. W. K. Vanderbilt's "Marble Palace," and the Goelet House, at Newport, R.I.; mansions in Beacon-street, Boston, the Vanderbilt Mausoleum on Staten Island, and a mansion, as yet unfinished, for Mr. Vanderbilt, at Ashville, North Carolina. Soon after his return to the United States Hunt took an active and a prominent part in founding the American Institute of Architects, a body which now has chapters in various parts of the United States. He succeeded R. M. Upjohn and Thomas U. Walter as president, and subsequently was elected president of the institute under its reorganised constitution. He was also for several years president of the New York Chapter of the American Institute. Soon after commencing his career in New York Mr. Hunt opened an architectural atelier for students on the French system. Many of the younger leading architects in America, including Professor William R. Ware, George B. Post, Frank Furniss, Henry van Brunt, and Charles Gambrill were students in this atelier. In 1867 Mr. Hunt served as a member of the fine arts jury at the International Exposition in Paris; in 1876 he held the same office at the Centennial Exhibition in Philadelphia; and in 1893 he served as a member of the fine arts jury of selection, and as president of the Board of Architects, at the Exhibition at Chicago, and the Administrative Building at that World's Fair was built from his designs. In 1882 Mr. Hunt received from the French Government the decoration of the Legion of Honour, and was elected a Corresponding Member of the Institut de France in the following year. He was an honorary member of the Société Centrale des Architectes Français, and of the Architects' and Engineers' Society of Vienna; and an Academician of St. Luke at Rome. Harvard University conferred on him the degree of LL.D., the first ever bestowed by that learned body on an architect. In 1893 the Royal Gold Medal of the Royal Institute of British Architects was awarded to Mr. Hunt, who had been an Honorary Correspondent of the Institute since 1886. Mr. Hunt, who, therefore, has been the only American recipient of the medal since its establishment 48 years ago, crossed the Atlantic to receive the medal at the hands of Mr. MacVicar Anderson, and acknowledged the honour in a bright and cheery speech, giving many personal reminiscences of his studies under Lefuel and his work at the Chicago Exhibition.

The death of Mr. G. R. Cobham, architect and surveyor, of Edwin-street, Gravesend, took place on Thursday afternoon in last week, the deceased passing away in his sleep. Mr. Cobham was well known and highly respected. He was secretary and surveyor to the Kent and Essex House, Land, and General Investment Company, secretary to the Gravesend and Rochester Equitable Permanent Building Society, a member of the Kent Archæological Society, and a member of the Education Committee of the Town Council.

The death is also announced, after a short illness, of Mr. Walter Lawrence Paul, architect and surveyor, at the age of 40 years. Deceased, who was the son of the late Dr. Andrew Paul, died at his residence in Furlong-road, Holloway, on Friday last.

The death is announced, at the age of sixty-seven, of M. Gabriel Auguste Ancelet, a well-known French architect, who, born in Paris, gained the Prix de Rome in 1851, a Médaille d'Honneur in 1867, and a gold medal in 1869, and was elected Membre de l'Institut in 1892. He entered the Legion of Honour in 1867. In 1873 he was appointed a professor in the Ecole des Beaux-Arts, and continued to act in that capacity until of late. His most important building in Paris is the new Musée des Arts et Métiers.

CHIPS.

Various improvements have lately been carried out at the Convalescent Hospital, Southport, from funds supplied by the Cotton Districts Convalescent Fund. The alterations include new dormitories for nurses and servants, and improved ventilation, and have been executed from plans by Mr. Charles Heathcote, of Manchester.

The new church at Sledmere, which Sir Tatton Sykes is building at his sole cost, is progressing in the hands of Mr. John Thompson, contractor, of Peterborough, who has already got in all the windows, including one of five lights in the east wall. The tower of the old church is to be preserved, and the nave of the new one is built into it. The older masonry will, however, be restored where necessary.

At Friday's meeting of the Perth Gas Commission, Mr. Foulis, engineer, Glasgow, reporting on the condition of the city gasworks, stated that the crowded state of the present works interfered prejudicially with the economy of manufacture. He approved of their proposed removal to the Sand Island.

The new Central Board School at Millbrook, near Southampton, will be publicly opened on Monday, September 2nd. Mr. A. F. Gutteridge, of Southampton, has been the architect, Mr. H. Cawte, of Shirley, the contractor, and Mr. H. M. Randall, the clerk of works.

The urban district council of Felixstowe and Walton accepted at their last meeting an offer from landowners of several strips of land forming cliff frontages to be laid out and maintained as pleasure grounds. The estimated value of the land is at least £500.

An alabaster tablet with black marble inscription panel, erected to the memory of the late William Watson Pattinson, J.P., of Felling House, was formally unveiled in Felling Church on the 8th inst. The tablet was furnished by Mr. Robert Beall, of Newcastle-on-Tyne, from designs by Messrs. Hicks snd Charlewood, architects, of the same city.

The city council of Coventry adopted on Tuesday plans by Messrs. G. and I. Steane, of that city, for a ward of 16 beds, a discharging block, and a porter's lodge to be added to the city fever hospital. The estimated cost is £4,850.

At the Town-hall, Colchester, on Wednesday week, a Local Government inquiry was held by Col. J. Ord Hasted into the application by the town council for a loan of £6,250 for water supply purposes. Mr. James Paxman, the chairman of the waterworks committee, after stating that the new machinery cost £16,000, said that the engineer, Mr. Wood, had inspected the water tower and found it incapable of bearing the strain which would be put upon it in order to support an adequate supply of water at a sufficient elevation. To do all that was necessary to secure absolute safety, including underpinning foundations and new flooring, would involve an expenditure of £12,000 or £13,000.

A Central Higher Grade School is being erected at Bolton. Messrs. E. and D. Maginnis are the contractors, the amount being about £20,000.

DURHAM COUNTY COUNCIL BUILDINGS.—ARCHITECTURAL ASSOCIATION EXCURSION SKETCHES OF GLOUCESTER, TEWKESBURY, ETC.—TYNEMOUTH PRIORY.—COTTAGE HOSPITAL, PORTH.

Our Illustrations.

DURHAM COUNTY COUNCIL OFFICES: SELECTED DESIGN.

The following particulars are from the report furnished us by the architects, Messrs. Harry Barnes and Frederick E. Coates, AA.R.I.B.A., of Sunderland. In this design the boundary lines of the site have been rigidly adhered to. The buildings do not occupy the entire site, but leave a strip of land 70ft. deep and 100ft. long at back of proposed building, which would be available for any future extension. The level of the ground floor is 8ft. above the footpath in Old Elvet, whilst at the rear of the building it is only 1ft. above the ground. The site having only one street façade renders a central entrance from that street imperative. On the east and south fronts, side entrances are planned, and at the south-east corner is placed the special public entrance to the council chamber gallery. The entrance to the office of weights and measures is at the north-west corner. The polling booth and caretaker's rooms have distinct entrances; that of the caretaker controls the cart entrance on the east side. An entrance for lift may be made on the west side of the site. The basement contains the weights and measures' offices and lavatory block, the county clerk's strong rooms and the county surveyor's plans and sample rooms, the caretaker, with the heating chamber, coals, &c. Upon the ground floor are provided the council chamber and committee-rooms, and the offices of the county clerk. Accommodation for the county surveyor, medical officer, accountant, and technical education officer are provided on this floor. The second floor has been devoted to the photographing rooms of the county surveyor, the laboratory of the medical officer, and the technical education library. The weights and measures offices have a direct separate entrance from the street. These offices are perfectly self-contained and upon one floor, and are well lit. The county clerk's strong rooms are easy of access from the clerks' office. They are well lighted, ventilated, and secure. The surveyor's plans-and-samples room is also well lighted, and is of easy access for both clerks and for the lift. The polling booth is well lighted. A separate entrance from the street carries the turmoil of election away from the administrative department. The caretaker's rooms, whilst being isolated and private, are in proximity to the lift and the heating chamber. The entrance is from the east side. A serving lift will be made from the kitchen to the waiting-room above. This waiting-room is intended to be used as a serving-room if at any time a luncheon is given in the large committee-room. On either side of the central entrance are placed the council department and that of the county clerk. These departments are self-contained, while the entrance to the upper floor is independent of the corridor of either department, both of which are absolutely private. Special attention is directed to the council chamber. This block, situated on the axial line of the plan, is two stories in height, and whilst of most easy access from all parts of the building, is yet completely isolated. Upon each side of the council chamber are grouped the committee, chairman, and waiting-rooms. This department is furnished with two spacious lavatory blocks. The council chamber is of horseshoe shape. An expert in acoustics gives it as his opinion that "this chamber will be possessed of the most perfect acoustical properties, and admirably adapted for the purpose of debate." The chamber has been kept as small as conveniently possible, according to request in schedule, and all useless corners which confuse sound are dispensed with. Consideration is asked to the means by which members may leave the chamber, and retire to the ante, committee, and retiring rooms, or public gallery, without crossing the central floor space; also to the fact that the side entrances would allow of the most rapid exit from council chambers in case of emergency. The chairman's seat is placed on a daïs, with the county clerk's and vice-chairman's seats on either side. This daïs will be so constructed as to prevent draughts, and also act as a sounding-board. The officials are placed together in front of the chairman, and the reporters' press-boxes are in a good position for both seeing and hearing members. The side entrances will be very convenient for sending out messages. It is not necessary for any official or deputation to pass through the ante-room, and the public gallery is under the control of the chairman, quite distinct, and entered from a special entrance. The entrances to the council chamber are so placed that they may be used in conjunction with the ante-room as division lobbies. The table in the centre of the chamber is useful for the display of maps, &c. The councillors' retiring-room is on the first floor, in a private position; one side of the room is pierced with glazed openings, by means of which members may see the progress of business; it may also be used as a members' private gallery on special occasions. Attention is drawn to the manner in which the portions of the council chamber block on the first floor are kept private from the offices on that floor. The committee-rooms are arranged round the council chamber and ante-rooms, which latter are so placed as to be equally available as cloakrooms for both council chamber and committee-rooms. The chairman's room overlooks Old Elvet, and is placed between the departments of county clerk and council chamber. The waiting-rooms are conveniently placed for deputations to both council and committee-room. The remaining portion of ground floor is devoted to the county clerk; these offices are under perfect superintendence of one head, whilst the corridor need only be used by officials. A door may be placed leading from the vestibule to the clerks' inquiry office. A separate staircase gives access both to basement strong-rooms and the offices above, and the hoist is in a central position. A good large strong-room is entered from the clerk's office. Excellent large areas are lined with glazed bricks, for continuous lighting of corridor, light on both sides of hall, and on three sides of the grand staircase, which is also lit by a cupola light. Attention is drawn to the means of access to the upper floors. Persons desirous of reaching any of the offices on the first floor do not touch the corridor of the ground floor. There is only one corridor from which all offices may be entered, and there are no narrow, inefficiently-lighted, dead, minor corridors, whilst the arrangements of stairs and exits are such as to furnish an exit at each end of corridor on every floor. Considerable attention has been given to the position of the central staircase. It has been placed in the centre of the building, from which all parts of the building may be reached with equal ease. The porter and switch-room, which is placed under part of this stair, commands the entire building. The drawing-office is well lighted from two sides, and is directly accessible to both surveyor and assistant surveyor. The plan-room shown on front may be used either as an inquiry office or thrown into the private office of the county surveyor. In these offices full accommodation has been provided. They have good light and access from side stair and entrance. The clerks' office is centrally placed between the medical officer and inspector. The second floor is devoted to a technical library, well-lighted, and conveniently placed for the lift. The walls of every strong-room are carried up from the ground level. The tower is built of masonry from top to bottom. No iron beams are to be used in its construction. The lavatories and w.c. blocks are placed against external walls, and the drains are clear of the building altogether. All lavatories and w.c.'s are disconnected by a lobby, and a special ventilating shaft is provided for each floor. The elevation towards Old Elvet will be built with buff terracotta. As the site lies in a hollow and is overlooked from many parts of the city, a copper-domed tower has been designed to give the building prominence and dignity. The roof will be covered with green Westmoreland slates. The flats over lavatory block will be of concrete and asphalte. The floors over corridor and staircases will be fireproof and laid with wood-block flooring. All the principal offices have open fires, and the building throughout is to be heated by low-pressure steam. The council chamber and ante-room are to be heated and ventilated on the Plenum system. The lighting to the chamber will be by a large ventilating sun-burner. The cubical contents have been carefully worked out, and amount to 550,800c.ft. In the opinion of the authors of this design, who have had experience in the district of this class of building, the works could be carried out for the sum of £18,000, including heating, furnishing, &c. The contract tender actually received amounted to £18,051.

THE A.A. EXCURSION TO GLOUCESTERSHIRE.

(See description and other illustrations on p. 217, *ante.*)

CHIPS.

The 13th-century parish church at Carlton Miniott is about to be pulled down and a new one built on the site. The contract for the work has been let to Mr. H. Harwood, of Mansfield, Darlington, for the sum of £1,020.

A marble bust of Mr. W. T. Best, late city organist of Liverpool, is to be placed on a bracket in front of the organ gallery in St. George's Hall, in that city.

An organ, built by Messrs. P. Conacher and Co., Huddersfield, has been opened in Haxley parish church, near York. The case is of pitch pine, with pipes decorated in gold and colours.

The parish church of St. Peter, at St. Alban's, which has been rebuilt at the sole cost of Lord Grimthorpe, will be rededicated on Tuesday, October 1st.

The Memorial Cottage Hospital at Crewe was opened on Wednesday evening by the Earl of Crewe. The style of the architecture is Elizabethan. There are three wards, each of six beds, and a smaller ward for two beds, also a matron's room, an operation-room, nurses' room, kitchen, and the usual other offices. The builder has been Mr. Gelhen, of Shrewsbury, and the architect Mr. Brooks, Manchester. The hospital is situated in the Victoria-avenue, facing the Queen's Park. The cost of the building has been about £3,000.

Western Australia is evidently determined to advance. In presenting the Budget to the Legislature of the colony on Friday, the Premier announced that it is proposed in the ensuing year to establish a mint, an observatory, a museum, and a library, to continue the Fremantle Harbour works, to erect a telegraph line across the Continent to Adelaide, and to construct gold-fields and other railways to the extent of 400 miles.

The restoration of the 14th-century church at Smallholm, near Earlston, is about to be carried out from plans prepared by Messrs. Hardy and Wight, architects, Edinburgh. With the exception of the restoration of the chancel arch and gables, and the nave, the expenditure will be limited to providing for the better accommodation of the worshippers. The work to be now done includes a new roof and floor, new seating, the addition of a north transept and vestry, and new ventilating and heating apparatus, at a cost of about £500.

Subject to Parliamentary sanction, an agreement has been entered into by the Wolverhampton Town Council with the Urban District Council of Bilston for the sale to the latter authority of (*a*) the water rights and water mains of the Wolverhampton Corporation in the Coseley area, and (*b*) the water main from Goldthorn Hill to the boundary of the township of Bilston, at the sum of £7,750.

The members and congregation of the new Baptist church, Padiham, have resolved to erect a new school-chapel in Shakespeare-street. When completed the building will seat about 700 persons.

The new line of electric railway to the summit of Snaefell, the monarch of Manx mountains, will be opened for traffic to-morrow (Saturday). The Board of Trade inspection by Colonel Rich and Major Cardew takes place to-day (Friday).

TYNEMOUTH PRIORY, NORTHUMBERLAND.

THE drawing of Tynemouth Priory published above is by Mr. H. S. Curry, who says:—"The church is Benedictine, and the east end, shown on drawing, was built in 1220, and the Lady-chapel added in 1400. It was in all probability used as a place of interment for the Percy family of Northumberland. The Priory was dissolved in 1539."

◆

The French Archæological School in Athens will celebrate its Jubilee in March, 1896.

On Saturday a new Wesleyan chapel was opened at Stocksfield. The building was built of Bearl stone, and was erected from designs by Mr. T. L. Anderson, of Newcastle-on-Tyne. It will accommodate 150 adults, and cost £650.

The church of St. James, Barton-under-Needwood, is about to be restored, at a cost of about £600. The upper part of the tower will be rebuilt, and the aisle and nave roofs, the mullions of clerestories and the buttresses restored, the work to be carried out by Mr. Bridgeman, of Lichfield. A new clock, striking the Cambridge quarter chimes, is to be placed in the tower by Mr. John Smith, of Derby, whose contract price is £158.

A Baptist chapel is about to be built in Crown lane, Maldon, Essex, from plans by Mr. P. M Beaumont, of that town.

The Government of New South Wales have been prompt in commencing the railways and other public works recently sanctioned by Parliament, and the result will be to find work for a large number of recently unemployed labourers. The works in question include the construction of a light railway, 63 miles long, from Narrabri to Moree; a similar line from Berrigan to Jerilderie; another from Parkes to Condobolin; a hospital for the insane at Kenmore, and the works in connection with the Newcastle harbour scheme.

Building Intelligence.

Edinburgh.—The plans for the first of the Thomas Nelson Hall and Branch Public Libraries are now before the Dean of Guild Court. The site chosen is at the corner of Dundee-street and Murdoch-terrace, immediately opposite the new subway to Dalry. The building will have a frontage to Dundee-street of two stories and one story to Murdoch-terrace. There is a large vestibule and entrance-hall, on the right of which is the Nelson Hall 75ft. by 33ft. 6in. In the centre is the lending library, with open counter to the inner entrance-hall for general borrowers, and on the left the reading-room, 75ft. by 18ft., with boys' room behind. The Nelson Hall will be fitted up as a news and recreation room, and will be provided with newspapers and games. It will be separated from the library by a glass partition in five arches. The library will contain accommodation for from 11,000 to 12,000 volumes, with light from the roof, and divided from the reading-room by a counter with a row of double columns and arches. The librarian can see into all these rooms from his desk. The upper floor contains staff and committee-rooms, stores, and caretaker's house. All the halls have open-timbered roofs, and the lighting is principally from large roof-lights. The elevations have large mullioned windows and doorway, supported by double pilasters on either side, with carved frieze and cornice. The architect is Mr. Harry Ramsay Taylor (of Lessels and Taylor), George-street, Edinburgh.

Lichfield Cathedral.—The completion of the adornment of the interior of the Lady-chapel and of the general restoration of the east end was celebrated on the 31st July, when there were also dedicated a new window in the end of the south transept and other special gifts for the enrichment of the cathedral, representing an outlay of £4,000, a sum raised entirely independent of the Reparation Fund. The new work included a new altar-piece, alabaster altar-rails, two windows of ancient glass, and ten statues in Staffordshire alabaster of the virgin saints and martyrs—the black-letter saints of the Calendar, together with two windows at the east end of the south choir aisle, one at the east end of the north choir aisle, one in the Chapter House, and a great Lonsdale memorial window in the south transept. The subject of this window is the spread of the Catholic Church under the figure of the true vine, which bears as its fruits the leading saints or bishops of the most important Early Christian sees. The names in the different lights are 22, and include six bishops of the Anglican Church and two bishops of Gaul. The window is a splendid work, and replaces a poor window put in by the canons of the cathedral in the early part of the century, the glass of which will be utilised in the higher windows of the choir. Another new window, the last but one on the east end of the south aisle, is given in memory of John Toke Godfrey Faussett, the subject being the defence of St. Stephen before the Sanhedrim. Next to it is a new window in similar style, given in memory of Dr. Halford Wotton Hewitt, Mayor of Lichfield in 1842. It depicts SS. Peter and John at the Beautiful Gate healing the cripple. These two windows harmonise with the older glass in the Brooke-Boothby window over Chantrey's Sleeping Children, and, like all the work, have been executed under the superintendence of Mr. C. E. Kempe. This latter window has been renovated, and the tracery exactly preserved. Opposite these windows, in the north aisle of the choir, is the new Patterson Memorial Window; this represents King David teaching the music of the Sanctuary to one of the chief musicians of the Sanctuary and the sons of Korah. In the Chapter-house another new window has been placed in memory of William Gresley, prebendary of the Cathedral. It is the fourth of an historical series in the Chapter-house in memory of Cathedral worthies that was begun under the care of the late Dean. Two windows, having a unique history, have been placed in the Lady-chapel. The glass of these two bears the arms of the kingdom of Aragon, and is believed to have been brought from the Low Countries after the violence of the French Revolution, between 1840-50; it was deposited in the cellars of Messrs. Christie, in London, where, unknown and forgotton, it rested many years. Through the instrumentality of Mr. C. E. Kempe, by whom it has been renovated, it was purchased from the executors of the late Marquis of Ely; it is of the Renaissance school, and is nearly the same date as the Herckenrode windows which Sir Brooke Boothby procured for the Cathedral in 1803. The new altar-piece is a richly-gilt triptych, in which the Incarnation is depicted, the Annunciation, the Salutation of Elizabeth, the Nativity, the Presentation in the Temple, and the Adoration of the Magi. All these are carved in relief. In the doors, which may be closed, are painted figures of Isaiah, David, John the Baptist, and St. Chad. The altar-rails are of carved alabaster, with pierced panels in designs of lilies, the work being by Mr. Bridgman, of Lichfield, and designed by Mr. Kempe. The ten pedestals and canopies in the window spaces have been filled with alabaster figures of the Virgin Saints, all depicted with their special emblems. These are the work of Messrs. Farmer and Brindley, of Westminster, the list being St. Werburga, St. Cecilia, St. Prisca, St. Faith, St. Catherine, St. Margaret, St. Lucy, St. Agnes, St. Agatha, and St. Ethelreda.

Newfoundland.—*The Evening Herald*, Newfoundland, gives a description of the reopening of the choir and transepts of the cathedral, dedicated to St. John the Baptist, on June 29. It will be remembered the building was almost entirely destroyed by fire in 1892. Triumphal arches were erected, on the occasion of the reconsecration, in the thoroughfares leading to the sacred edifice. The work generally has been carried out under the personal direction of Mr. Wills, who acted as clerk of works of the original building, and from the designs of Messrs. George Gilbert Scott, M.A., F.S.A., and John Oldrid Scott, F.S.A., architects, of Spring-gardens, London. Most of the internal fittings are special gifts. The oak eagle lectern is a reproduction of the burnt one. The carved oak bishop's throne, sedilia, and stalls, which, like the lectern, are intrusted to Messrs. Harry Hems and Sons, of Exeter, to carry out, have not yet arrived. There is a handsome new pulpit and altar.

Norton-sub-Hamdon.—The ceremony of reopening the tower of St. Mary's Church, Norton-sub-Hamdon, and dedicating the new font and peal of six bells, took place last week. The tower was struck by lightning on Sunday, 29th July, 1894, and the woodwork in the tower was completely destroyed—the bells falling to the bottom. Much damage was also done to the roof, the seating, organ, font cover, screen, and other furniture of the nave. These have all now been made good. The church was rebuilt in the early part of the 16th century, and is all of Ham Hill stone, and in one uniform style, with the exception of the porch, which is quite a century earlier in date. A general restoration of the interior took place about 30 years ago, at a cost of over £1,000. The whole of the inside work of the tower is now reinstated in the best materials of all kinds. Six bells, cast by Messrs. Warner and Co., of London, are now provided in place of the melted and broken peal of five. A clock, playing the Westminster chimes, has been obtained from Messrs. John Smith and Co., of Derby. The whole of the stonework has been repaired as needed, and four new additional detached pinnacles have been added, as originally provided for, but not put up, in the centre of each face of the tower, standing on the old gargoyles. These pinnacles are a gift of the Ham Hill Stone Company, and give a crowning effect to the beautiful tower. The upper tower windows are now filled with new tracery panelling, in place of the old boarding, affording richness and strength to each face of the tower at this stage. The inside face of the walls is as red as brickwork from the effects of the fire, but the strength of the building is not reduced. On the east and west corners of the battlements of the south side of the church new pinnacles have been placed of the same form as the intermediate existing old ones. These have been given by Mr. W. Micklewright, of Norton, foreman to Messrs. C. Trask and Sons. The fine west window has been re-glazed to patterns designed by the architect, by Mr. Drake, of Exeter. Under the west window is the fine doorway, for which new oak doors have been given. All the carving, both wood and stone, has been executed by workmen of the parish, who have shown great interest in it all through. The new screen to replace the old one in the tower arch, and forming the vestry, is not yet finished. A baptistery has been formed at the west end of the south aisle. The floor of this part is now of black and white marble, and the new font is of Derbyshire alabaster; the square vase is moulded, and carved fishes at the angles bring the square to the circular shape of the font itself, the outline of which is a tapering drum-shape with spiral mouldings, carved with foliage at the upper terminations of the flutes. The cover is not yet provided, but it will be of oak, with a projecting moulding. The ceiling has been coloured throughout under the directions of the architect by Mr. Howe, of Crewkerne. The architect has been Mr. H. Wilson, of Oxford-street, London, the successor to the late Mr. J. D. Sedding, by whom every detail of the new work has been designed. The organ has been restored and improved by Messrs. Griffen and Stroud, of Bath. The leadwork for the tower has been done by Mr. Joseph Dunn, of Crewkerne. The cost of the work has been upwards of £1,600.

Upton, Cheshire.—A special meeting of the Cheshire County Council was held on Friday at Chester Castle to consider the question of extending Upton Asylum. Some time ago the Council engaged Messrs. Grayson and Ould, architects, Liverpool, to prepare specifications for the proposed work. The architects estimated the cost at £80,000, and this amount was granted by the council and tenders asked for. When, however, these came in, it was found that the lowest tender was £15,300 in excess of the architects' estimate. Mr. Thompson, chairman of the committee of visitors to Upton Asylum, said the architects' explanation was that since they furnished their estimate a rise had taken place in the price of labour of from 10 to 12½ per cent., and there had also been an increase in the price of materials. To invite discussion, he moved: "That the sum of £25,000 be granted in addition to the sum of £80,000 already granted for the purpose of carrying out the enlargement of Upton Asylum." Mr. Chetham moved the following amendment: "That the report be referred back to the Visiting Committee for further consideration, and with a view to their submitting reliable estimates of the cost of carrying out plans already approved." The amendment was carried by a large majority.

CHIPS.

The foundation-stone of the Verdin Technical Schools for Northwich will be laid early in September. Mr. Joseph Cawley, of Northwich, is the architect.

A stained-glass west window, the latest gift to St. Stephen's Church, Bournemouth, is now completed. The lower part contains twelve scenes from the history of St. Stephen.

The Sheffield Smoke Abatement Association have adopted a practical scheme for modifying the pollution of the atmosphere by smoke. It is now generally recognised that the amount of black smoke emitted from the chimneys is dependent upon the amount of care exercised in firing. The association have decided, on condition that the manufacturers co-operate with them, to award money prizes to engine-drivers and stokers for the lowest records of black smoke emission from boiler chimneys in proportion to the weight of coal consumed.

At Southwark, on Wednesday week, the Pomplet Torbay Paint Company were summoned by the Torbay Paint Company under the Merchandise Marks Act for having applied a false trade description to certaint paints sold by them. It was alleged that they used the word "Torbay" for their paints, conveying the idea that they were manufacturers of Torbay paint, which was exclusively produced by the prosecutors. The magistrate thought the case had been made out, and fined the defendant company £10, with 20 guineas costs.

The directors of the North British Railway have decided to double the line between Arbroath and Montrose, a distance of about 14 miles, authority for which was obtained from Parliament some time ago. The work will be begun immediately.

For ventilation of the Stoneyholmne new board schools, Burnley, Mr. William A. Quarmby, architect, Messrs. Cousland and Mackay's patent improved "Climax" direct-acting invisible roof ventilators are used, and a large number have been supplied by that firm.

The committee of management of the Certified Efficient Voluntary Elementary School at Pyrton, near Watlington, Oxfordshire, have accepted the drawings for a new school prepared by Mr. R. Spyer, architect, Watlington, which have since been approved by the education department. The style of architecture may be somewhat paradoxically described as modernised Old English with some Elizabethan features, and in keeping with the rural surroundings. The works are being executed by Mr. G. Glanville, of Pyrton, and Mr. J. Rockley, of Shirburn, is clerk of works.

UNIVERSITY COLLEGE.

THE following are the prize lists in Architecture, Civil Engineering, and Surveying at University College:—

Architecture (Professor T. Roger Smith, F.R.I.B.A.).—Fine Art.—Donaldson Medal: V. A. Flower, of London. Prize: A. M. Watson, of London. Third Class: A. S. R. Ley, of Brackley. Construction.—Donaldson Medal: A. T. Coode, of London. Prize: J. S. Heath, of Blackheath. Certificates (3): J. N. Snell, of Bromley; (4) A. E. Nicks, of London. Second Class: F. Moore, of Bickley. Third Class: J. M. R. Alves, of Brazil; F. J. Freeman, of Blackheath; H. T. Nation, of Bedford. Classes maintained by the Carpenters' Company: Architectural Drawing.—First Prize: H. L. Bunn, of London. Second Prize: L. Cabuche, of London. Third Prize: G. Jacob, of London. Construction Drawing.—Prize: O. J. Potter, of London. Measuring and Quantities.—First Prize: F. Stacey, of London. Second Prizes (eq.): S. Green, of London, S. Porter, of London. Third Class: F. B. Chester, of London; Sidney Ebbs, of London; E. A. V. Garnham, of London; A. S. Seaman, of London.

Civil Engineering and Surveying (Professor L. F. Vernon-Harcourt, M.A., M.I.C.E.)—Civil Engineering—Prize: J. G. Mathieson, of London. Second Class: J. E. Petavel, of London. Third Class: J. M. R. Alves, of Brazil; F. D. do Prado, of Brazil. Surveying—Prize: W. Cooper, of London. Second Class: W. M. Park, of London; J. H. Trenerry, of Gibraltar. Third Class: W. N. Withers, of Shrewsbury.

CHIPS.

The route of the projected new line of railway from Stert to Westbury was inspected on Saturday by Lord Emlyn, chairman of the Great Western Railway Company; Mr. H. Lambert, general manager; Mr. Inglis, chief engineer; and Mr. Allen, superintendent of the line.

Mr. J. Passmore Edwards has offered, provided the ratepayers will find a suitable site and adopt the Free Libraries Act, to erect in the parish of St. George the Martyr, Southwark, a free library similar in capacity to that in course of erection in Hammersmith.

Some very desirable alterations have been made at the Royal Sailors' Home, Duke-street, Devonport, by the erection of a new Portland cement front, in place of the wooden structure. Messrs. Healy and Sons were the contractors for the work, which has been carried out according to designs prepared by, and under the superintendence of, Mr. H. G. Luff, A.R.I.B.A., of Devonport.

Mr. Jasper J. Kelf, of Walthamstow, has taken into partnership Mr. Arthur Mullings, who for the past nine years has been with first-class City firms, the last three years of which he was with Mr. Fred Chancellor, F.R.I.B.A. The business will in future be carried on under the style of Kelf and Mullings.

The new infirmary at Isleworth, for the Brentford Union, is nearing completion. The building is three stories high, and consists of four pavilions, of three wards in each pavilion. It has been erected from the designs, and under the superintendence, of Mr. W. H. Ward, architect, of Birmingham. Mr. T. J. Messom, of Twickenham, is the builder. The whole of the wards are warmed and ventilated by means of Shorland's patent ventilating Manchester stoves, with descending smoke-flues, two stoves being fixed in each ward, the same being supplied by Messrs. E. H. Shorland and Brother, of Manchester.

At the meeting of the urban district council of Morecambe on Monday, recommendations by the roads, sewers, and improvement committee that a shelter and convenience be erected at the West End on a new bay projecting from the Promenade at a point central between the new West End Pier and the Battery Pier were unanimously approved. The committee were also authorised to prepare a scheme for extending the sea-wall and promenade from East View to Bare White House, on the lines submitted by the surveyor.

The trade in wood blocks for paving purposes is expanding in New South Wales, the demand being principally on English account. Messrs. Burns, Philip, and Co., Sydney, had, on the despatch of the mail, received an order by cable for 600,000ft., for immediate delivery.

The large statue of the Queen, which is being executed for Rangoon by Mr. F. J. Williamson, sculptor to her Majesty, is approaching completion, and, when erected, will, it is stated, be the first piece of sculpture in marble in the Burmese city.

A special committee of Aberdeen Harbour Board reported on Tuesday to the commissioners that they had under consideration the subject of the vacancy in the office of harbour engineer. The committee recommended that the salary of the engineer be fixed at £500 per annum, and applications for the post invited by advertisement, the proposal of the minority being that Mr. Robert G. Nicol, the present assistant engineer, should be appointed as interim engineer at a salary of £350 per annum. After the commissioners had deliberated in private, it was unanimously resolved that Mr. Nicol be appointed interim engineer on the terms mentioned.

Engineering Notes.

The Daventry and Marton Railway.—The new loop-line which the London and North-Western Railway Company have constructed between Daventry and Marton, near Leamington, was opened for passenger traffic on the 1st inst. The new stations are at Long Itchington (for Southam), Napton (for Stockton), Flecknor, and Braunston. It is not proposed to use the line for the Birmingham express service to and from London until the embankments have settled. The line has been constructed by Messrs. Walter Scott and Co., of Newcastle, at a cost of over £250,000. The gradients are variable, and in some places steep, and the principal engineering feats are viaducts over Daventry and Braunston reservoirs and a deep cutting through the lias formation at Stockton. The line is nearly fourteen miles long.

The Waterloo and City Railway Company.—At the half-yearly meeting of this company the chairman read a report signed by the engineers, Mr. W. R. Galbraith and Mr. J. H. Greathead. It stated that, commencing in the river, and driving in each direction, the tunnels had passed entirely beneath the bed of the Thames, and towards the City had been carried under the Thames Embankment wall, the Metropolitan District Railway, and the complication of sewers and subways which were concentrated at that point. Towards Waterloo the tunnels had also made good progress, and had passed underneath the whole of the buildings situated between the south side of the Thames and Stamford-street, and they were now being driven under the roadway of the street. The total length of single tunnel driven during the past six months by the contractors, Messrs. Mowlem, Burt, and Co., was about 1,200 yards. There was nothing apparently to prevent the tunnels from being driven at full speed towards the Mansion House, the borings having disclosed an ample cover of solid London clay in that direction. Towards Waterloo both tunnels had cleared the buildings between Stamford-street and the river, and would be driven wholly under the street, without interference with private property, until they reached a point a little eastward of the Waterloo Bridge-road. The arrangements for the City terminus were under discussion with the Central Railway Company.

Insch and Gartly, N.B.—Operations were commenced on Monday with the doubling of the main line of the Great North of Scotland Railway between Insch and Gartly. At present the track is double from Aberdeen as far as Insch, a distance of 27 miles, and the additional line will extend about eight miles further. The company possess land which was secured under their original Act, for completing the doubling of the line all the way to Keith, and the present instalment will greatly facilitate the working of the trains. In the mean time, the line is single beyond Insch to Keith. There are no engineering difficulties to be encountered, and the extension will be accomplished by the company's own workmen. The only station affected will be Wardhouse, where it will be necessary to provide an additional platform for the down trains. The company are also just now pushing on improvements at other stations on their system, including Aboyne, Banchory, Buxburn, and Elgin.

◆

The parish church of Cleland, Lanarkshire, was reopened on Sunday, the 11th, after undergoing extensive renovations.

At a meeting of the corporation of Bury St. Edmund's on Tuesday a petition was read from a number of representative Jews in London and elsewhere, praying the corporation to reconsider a proposal to convert the old Jews' house, Meyses Hall, into a fire-engine station. The petition stated that the building dated back to the twelfth century, and that there are only two or three such buildings in England, that at Bury being the best-preserved. It was ultimately decided to refer the matter back to the committee.

Mr. George Armitstead, ex-M.P. for Dundee, has forwarded a letter to Lord Provost Sir James Low intimating his intention of presenting to the city his portrait by Mr. Arthur C. Cope hung at the recent exhibition of the Royal Academy. The letter was read at a meeting of the Town Council on Tuesday; when a remit was made to have arrangements made for the picture being formally presented to the community and placed in the Victoria Art Gallery.

COMPETITIONS.

Tendring.—At the last meeting of the Tendring board of guardians, the report was read of Professor T. Roger Smith, F.R.I.B.A., upon the plans of the proposed workhouse infirmary which had been submitted to him. This report stated: "After very careful consideration of the designs, I have no hesitation in recommending the design of Mr. Whitmore, of Chelmsford, for adoption. It is the most compact design; it is thoroughly well ventilated, and with ample light. It provides a good substitute for day-rooms. Those services which, if provided at all, should be isolated, are very completely isolated, and yet within reach of supervision. The arrangement of baths and closets is excellent; and though I do not find much to praise in the perspective view sent, I am of opinion that, if built, this infirmary would have a fairly satisfactory appearance. Last, but not least, this is the most economical design of those submitted, and it is to the architect's credit that a careful approximate estimate of cost appears to have been made by him." It was resolved that, before adopting any plan, Mr. Whitmore be asked to state, for the board's information, what his inclusive charges would be for preparing all necessary works, plans, and superintending the execution of the work.

◆

An effort is being made in Plymouth and Devonport, at the suggestion of Mr. E. M. Leest, to form a local architectural society, for the mutual benefit and education of the large number of architects, assistants, and pupils of the town.

At the Wolverhampton Police-court, on Friday, Henry Moore, builder, Walpole-street, was charged on two summonses, issued at the instance of the corporation, with using, in the erection of a building in Rugby-street, mortar which was not of the quality required by the by-laws. On the sample of mortar being analysed by the borough analyst, it was found to consist of only 13 per cent. of lime, the remainder being sandy loam and street sweepings. Defendant was fined £5 and costs, amounting together to £10 9s. 6d., and the stipendiary, expressed his regret that he could not make it ten times more.

The bronzed plaster model of Mr. Brock's statue of the late Sir Richard Owen, which has been exhibited at the Royal Academy during the summer, was moved on Saturday to the Natural History Museum to enable the Owen Memorial Committee to judge as to the general effect of the work and in order that the Trustees of the British Museum may determine as to the ultimate site of the statue. The model has been placed on the right of the great entrance-hall, against one of the terracotta piers. The question whether the statue is to be of marble or bronze yet remains to be determined by the committee.

A public meeting was held on Friday at the St. James's Hall, Derby, for the purpose of considering a scheme for the construction of an electric (light) railway from Derby to Ashbourne. The proposal is to build and work a railway on the overhead electric system. The line is to be connected with the existing Derby tramway, which terminates on the Ashbourne-road. Thence it will run through Mackworth, Kirk, Langley, and Brailsford into the town of Ashbourne. The line will be laid on the western side of the road, through nearly the whole length, but through the villages it would run in the centre of the road. The present railway journey from Derby is by a circuitous route, occupying about 1¾ hour, whereas by the new line the distance would be covered in 75 minutes. A rough estimate of the expenditure, including the cost of permanent way, materials, and laying, together with lands, buildings, and rolling stock, works out at £62,300.

A chemical and science wing is about to be added to the Stepney and Bow Foundation School. The architect is Mr. Howard Chatfeild Clarke, of 63, Bishopsgate-street Within, whose design was selected in competition. The new building, which is to be two stories high, is now being proceeded with on the vacant land between the present school premises and the churchyard of Holy Trinity Church. The plan embraces on the ground floor a physical laboratory for 25 boys, and a room for mechanical instruction for 25 boys. On the upper floor there will be provided a chemical laboratory also for 25 boys, and a lecture-hall to accommodate 50 boys. The elevation corresponds with the school buildings, and will be constructed with Suffolk bricks, with stone dressings to the windows and doorways. The interior walls will be faced with Ruabon bricks, with glazed brick dados, no plastering work being used. The floors of the new wing are to be wood-blocks. Messrs. J. and H. Cocks are the contractors, the amount being just over £2,000. Mr. J. P. King is the clerk of works.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

Cambrian Archæological Association.—The forty-ninth annual meeting of this association is being held this week at Launceston. On Monday the committee met at the White Hart Hotel to receive the reports of the officers, and for the transaction of other business. On Tuesday there was an excursion to Tintagel, followed by a public meeting in the Guildhall, Launceston, at which the President delivered his inaugural address. Warbstow Barrow was visited on Wednesday, and in the evening the annual general meeting of the association was held. Tavistock and Dartmoor were the object of the excursion of Thursday, the rendezvous to-day (Friday) being the Cheesewring. This evening another public meeting will be held in the Town Hall, when several papers will be read. To-morrow (Saturday) the various objects of antiquarian interest at Launceston will be inspected, including the Castle, the South Gate, the ruins of the Priory, and the churches of St. Mary Magdalen, St. Thomas the Apostle, and St. Stephen's. The arrangements were made by Mr. Otho B. Peter, F.R.I.B.A., the local secretary.

CHIPS.

The Manchester corporation have decided to hang the portrait of the late Dr. Fraser, by Sir John E. Millais, bequeathed to them by the widow of the bishop, in the town hall.

The Bromsgrove board of guardians have instructed Mr. G. H. Gadd to prepare plans and specification and superintend the carrying out of proposed alterations at the workhouse, at 5 per cent. on the outlay.

The Divisional Court of the Queen's Bench have dismissed an appeal by the London County Council against the rating of Brockwell Park. The Judges were of opinion that the Council had a beneficial, if not a profitable, occupation of the park, and was, therefore, liable to be rated. The case was remitted to the magistrates in order that the proper rate of assessment might be ascertained.

At the last meeting of the Manchester town council, Mr. J. Holme Lewis was appointed as engineer and manager of the hydraulic pumping station and supply at the salary of £300 a year, Mr. T. G. Edge as an engineering assistant in the city surveyor's department at the salary of £200 per year, and Mr. J. J. M'Kie as an assistant engineer on the main drainage works at the salary of £250 a year.

At the meeting on Thursday of the Warwick Town Council, the Highways Committee reported in favour of extending the water adits at Haseley by 183 yards, at a cost of about £1,700, to augment the water supply of the town. It being urged that the work was absolutely necessary to insure a continuous supply, the recommendation was adopted by a large majority.

An organ has just been placed in the chancel recess of the Presbyterian Church recently rebuilt in Fisher-street, Carlisle. Messrs. Alexander Young and Son, Eldon-street, Manchester, were the builders, and also made the case, which is of pitch pine and St. John's pine. The work was designed and the decoration arranged by Mr. T. Taylor Scott, F.R.I.B.A., of Carlisle, the architect of the new church.

The district council of Handsworth have decided to erect a technical school, at a cost of £11,500, on a site at the corner of Goldshill-road and Stafford-road, in that town.

The Duke and Duchess of Westminster opened, on Friday, the new Technical Schools and Gymnasium, presented to Winsford, in the salt district of Cheshire, by Mr. Joseph Verdin, of the Brockhurst, Northwich, at a cost of £8,000, contributed from money originally intended to compensate property owners suffering from the subsidence. Messrs. Woodhouse and Willoughby, of Manchester, were the architects.

The Winchester rural district council met on Saturday last to appoint a surveyor for their district. There were 68 candidates, six of whom were interviewed by the council, when Mr. W. F. Y. Molineux, surveyor to the Shifnal rural district council, was appointed with a good majority. Mr. Molineux served his articles with the borough surveyor of Shrewsbury (Mr. W. C. Eddowes). In 1887 he was appointed as surveyor to the Shifnal highway board, and in 1889 he was also appointed surveyor to the Albrighton highway board, the adjoining district. These appointments he held till March last, when the two boards were dissolved and merged into the Shifnal rural district council, Mr. Molineux being appointed as surveyor. His new district comprises 24 parishes, with 220 miles of roads. The salary is £200 per annum.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—E. J. S.—C. R. and Co.—W. F. Hartley.—Semper Fidelis.—G. S. and W. S. Co.—B. M.

E. R. D. (The Session 1894-95 of the "B. N." Designing Club closed with "A Riverside Bungalow," illustrated in our pages on July 12th last. The next session opens in the autumn, when the List of Awards will be published, and particulars of the new session will be given.)

Correspondence.

TOXTETH INFIRMARY LIGHTNING CONDUCTOR.

To the Editor of the Building News.

Sir,—The Liverpool Press of the 8th inst. contained a short account of a trial at the Liverpool Assizes which, if left unexplained, might add professional injury to serious monetary loss. May I give, on behalf of my firm, the following simple facts, without comment of any kind?

In 1891 the Toxteth guardians appointed my firm architects for their proposed hospital in Smithdown-road, and the buildings were completed a few months ago to the entire satisfaction of the board, and without any extras upon the contract, although the outlay was about £30,000.

The buildings include a chimney 200ft. high, and a sum of £25 was included in the quantities for a lightning conductor, to be made by some special contractor the architects might approve. This sum was deducted in the final certificate given to Kelly Brothers, the builders, leaving the guardians to pay direct for the conductor. Although this certificate was in the hands of the guardians some weeks distinctly showing the £25 deduction for the lightning conductor, no exception whatever was taken thereto until after they had received an account of £163 19s. 6d. for such lightning conductor, when on Kelly Brothers' clerk going for payment of the balance certified as per contract, he was persuaded to take £25 more than was certified, which on being handed to Kelly Brothers they returned by cheque, protesting against what had been done; but the guardians' clerk refused to receive the cheque, which ever since has been in the contractors' hands, waiting the disposal of the guardians.

The last account sent in was from Mr. Joseph Ball, steeple jack, Oldham, for lightning conductor, which he sent direct to the guardians, and was by them sent to the architects for report, the amount charged being £163 19s. 6d., 1,872ft. of copper being charged for on a chimney 200ft. high, owing to a most novel method of measurement being adopted, which brings the work up to £163 19s. 6d., instead of about £38, if measured by lineal length in the ordinary way.

A special meeting of the building committee of the guardians was called to consider the account, at which, instead of giving any version of my own as to the meaning of the somewhat peculiar wording of the accepted estimate, the committee read it for themselves, unanimously took the same view that had been taken and acted upon by the architects on their behalf, saying they would themselves have accepted the estimate had it been before them, endorsed their architects' action, and told me their clerk would now take up the matter direct, of which my firm at once officially informed Mr. Ball, and yet within a few days my firm received a writ for the amount claimed.

On the following day the clerk wrote my firm, officially giving them the decision of the meeting, and saying, "The guardians repudiate the claim of Mr. Ball, beyond that established by the copy of the correspondence between him and the architects, and submitted to the building committee."

After receipt of the writ I attended a board meeting and requested the ratification of the above decision, and the following resolution was passed at a subsequent meeting: "The advice of the solicitor be adopted, to refuse the ratification asked for, and leave the parties to their respective remedies."

The next step was an effort to bring about a settlement by arbitration, to which the plaintiff Ball agreed, but the guardians refused. My firm then offered to abide the result of a reference, which he then declined; then the action went on, the architects being absolutely powerless to do more than defend themselves.

Now as to the case itself. The whole question was one of the meaning of the letter or estimate referred to, which the building committee and architects alike understood to mean the measuring of the lightning conductor from end to end at the price quoted of 1s. 9d. per foot, but which Ball read as meaning the reduction of all the work to a standard of a tape, and by which the cost was increased eight or nine times.

Alike in the architects' request for a price for the lightning conductor, and in the estimate given in reply, the conductor required and estimated for was to be "similar in every way to that on the destructor chimney in Liverpoool," which the plaintiff Ball had himself fixed, and for which (exclusive only of extra work ordered by the city engineer) he charged £16 7s., which at 1s. 6d. per foot, as per his estimate for same, shows his own method of measurement to be per foot lineal for the chimney agreed upon as the model; for if taken the other way his bill would, of necessity, have been several pounds above what he himself had charged.

Instead of doing the work as on the chimney agreed, an entirely different method was adopted, five rods of copper of enormous length and weight being brought on the job without our knowledge—four for the angles of the iron cap, and a fifth of greater height, which it was found impossible to fix properly, and was finally removed, although included in the account sent in. These rods were neither ordered, approved, nor certified for by the architects, who suggested another method of equal reliability and ordinary cost; but Ball insisted that the only safe conductor for this chimney head was the method he was using. No further objection was raised thereto by the architects, who—considering the estimate one of lineal length only—felt that, at most, it could but mean a few extra lineal feet of measurement, at 1s. 9d. per foot; and the work as done, if so measured, would have amounted only to about £38, instead of the £163 19s. 6d. claimed on a method of measurement of which, until the trial, I never heard of, or ever met with any one who had.

Estimates have been received from several of the best firms in the country (upon actual detail drawings of the chimney), and all of them show upon the tracings sent with their estimates the usual method of fixing with collar at the chimney mouth, conductor, rod, and points; and their price, including everything, ranges from 1s. 6d. to 2s. 7d. per foot of chimney height, and a list of 23 conductors, taken indiscriminately from the books of one of my firm's expert witnesses, showed the actual cost thereof to average 1s. 6d. per foot of chimney height.

RESULT.

The verdict has the following effect:—

(1) The architects have to pay £140 for the lightning conductor fixed to the guardians' property, notwithstanding their action, and correspondence in the matter, being unanimously endorsed by the building committee, the architect's only interest in or benefit by it being their 25s. commission on the £25, included in the quantities for this work.

(2) By the ridiculous and unreasonable method of measuring in this case, work which, if done like the Liverpool destructor chimney, as agreed, and by ordinary measurements, would have come within the £25 allowed, has been made to cost £140, and in consequence of the amount being thus made in excess of the £25 to which the architects were entitled to bind the guardians, they have been brought in as personally responsible.

(3) That whilst ample evidence by experts was produced showing the work done to be absolutely wasteful, extravagant, and unnecessary, the architects have been made to pay for all, as the reduction of £23 19s. 6d. made by the judge would not on Ball's prices more than cover the fifth rod charged for but not used. Hence, whilst they had the several estimates beforenamed to complete the work in all respects for 1s. 6d. per foot of chimney height, they have been ordered to pay at the rate of 14s. per foot for what is, in their opinion and that of experts of the highest authority, not so good for the purpose.

The board of guardians, for whom the work was done, alone derive any benefit therefrom, and even had they paid the claim in full they would have got out of a £30,000 outlay, with the almost unique extra bill of only £140.—I am, &c.,

22, Sir Thomas-street, C. O. Ellison, J.P.
Liverpool.

DURHAM COUNTY COUNCIL BUILDINGS.

Sir,—Will other competitors be so good as to give us formal permission to attach their signatures to a protest (a copy of which we inclose) that we purpose sending the County Council of Durham by mutual consent of those competitors who have been approached on the matter? Intense indignation has been justly aroused at the council's action in setting aside the spirit of the assessor's award and giving the work to local men. Your earliest attention to this will greatly oblige and facilitate our action.—We are, &c.,

Philip Tree and Ivor Price
("Development").
Architects to the New Municipal
Buildings, King's Lynn.
4, Ludgate-circus, E.C., and St. Leonard's-on-Sea, August, 1895.

To the Chairman and Members of the Durham County Council.

Gentlemen,—We, the undersigned, with very great pleasure and considerable hard work, responded to your invitation to submit designs in open competition for the new Council House and Offices in Old Elvet, Durham, under conditions, which we humbly submit have certainly not been fulfilled in the spirit in which they commended themselves to us all. The result is that a gross injustice has been done to honourable and brilliant professional gentlemen, by their being set aside, without any valid reason, as if incompetent and unworthy, and local men, more or less unknown, substituted; who by your Assessor's award had not earned the honour of being intrusted with so important a public work. We therefore humbly and respectfully pray you to remove this most unmerited slur and bitter disappointment, by intrusting Messrs. Cooksey and Cox with the work they fought for and so gallantly won, and thus not only earn the esteem of the competitors and profession generally, but, we earnestly believe, act in the best interest you represent.

Philip Tree and Ivor Price.
Hon. Secs. for the Competitors.

[Here will follow the List of Names.]

* * *

At the annual meeting of the Amateur Photographic Association held on Tuesday at 58, Pall-mall, a large number of portraits of eminent men, taken for the National Collection of photographic portraits now being formed at South Kensington Museum, were highly eulogised by the Council, and passed, to be added to the collection.

At Tuesday's meeting of the Stratford-on-Avon Town Council, the completion was announced of an important work—the provision of an independent water supply from the canal for street watering and flushing purposes. The borough surveyor submitted specifications and quantities for the new service reservoir at Snitterfield, and instructions were given him to advertise for tenders.

Intercommunication.

QUESTIONS.

[11395.]—**Concrete Arching.**—Will any reader give results of experiments on strength of Portland cement concrete in the form of arching, or say where well-authenticated information may be found. Where possible, the following should be stated:—1. Span, rise, and thickness at crown. 2. Composition, and age of concrete. 3. Precise conditions of loading. 4. Rigidity or otherwise of abutments. 5. If a single arch, or one of a series. Can a formula for ordinary cases be stated?—Sigma.

[11396.]—**Thickness of Arches.**—Is there a simple, practical rule for determining what thickness the crown of an arch in masonry should be? I shall be glad of any information.—A Builder.

[11397.]—**Ventilation of Rooms.**—Authorities vary much as to the quantity of air required per head per hour. What is thought to be an average allowance for health, and how often should it be changed?—Student.

[11398.]—**House Drains.**—Will a practical reader inform me what inclination a house drain should have, and the minimum rate of fall for the necessary velocity; also the most effective jointing for the pipes under the house, and if any of the patented joints are found to give better results than the ordinary cement jointing?—A. B. M.

[11399.]—**Rolled Joist.**—I want a formula for giving the strength and safe load of rolled joists?—K.

[11400.]—**Shelving.**—Will someone kindly inform me of the usual number of books allowed per foot of shelving for a public lending library, and also for a reference library? Authorities seem to differ.—Edward B. Wetenhall.

REPLIES.

[11391.]—**Workmen's Houses.**—The Building News has published many plans and elevations of houses of this class. Consult the old volumes. As to cost, "A. A." had better find out the average cost per foot cube of such buildings in the neighbourhood of Glasgow. Near London, the cost of such dwellings varies from 4d. to 6d. per foot cube.—G.

[11393.]—**Ice Chambers.**—"Colonial" will find what he wants in the *English Mechanic*. See the vols. of that journal in any public library.—R.

[11394.]—**Cement Facing.**—In reply to "J. C.," why not leave the Portland cement? It is an ageeeable colour, if the sand is well selected. The rendering coat may be 1 of cement to 3 or 4 of sand, and for the "fining" or finishing coat 1 of cement to 2 of sand. This should be hand-floated. Keene's cement is only suitable for interior work. A white colour for the panels would not be so pleasing to the eye as the grey or stone colour of the cement.—G. H. G.

CHIPS.

Mr. W. J. Bird, C.E., one of the inspectors of the Local Government Board, held an inquiry at Colwyn Bay, on Tuesday, respecting the application of the district council for a loan of £1,200 to purchase the foreshore for the erection of a sea wall and promenade.

For a vacancy in the representation of St. Paul's ward in the town council of Wolverhampton, Mr. R. W. Berrington, who until recently held for a period of ten years the post of borough engineer, has issued his address as a candidate. It is expected Mr. Berrington will be returned without opposition.

Mr. James Rippoth Bonny, late surveyor to the Great Western Railway Company, died at his residence in Grove Park, Lee, on Thursday in last week, aged 68 years.

On Saturday the memorial-stone of the Volunteer Drill-hall, which is being erected in Market-road, Carluke, by D (Carluke) Company, 9th L R.V., was laid with Masonic honours. The contract is being carried out by Messrs. Martin and Symington, of Carluke.

The London and Provincial Builders' Foremen's Association intend holding their second annual dinner to-morrow (Saturday), the 17th inst., at "Ye Old Four Swans Hostelrie," Waltham Holy Cross. The president, Mr. W. Ebden, will take the chair. Dinner will be served at 4.15 p.m., and as there is a convenient train service from Liverpool-street, a large company is expected.

A new railway from Nottingham to Scarborough is in contemplation, the latter town being approached viâ the Wolds of the East Riding, which are not at present tapped by any system.

The Dundee Town Council decided on Monday to provide, at a cost of £8,000, filtration works for the purification of the supply of water from Monikie.

At the monthly meeting of the Worcester city council, on Tuesday, Mr. A. H. Hodder, of the Worcester School of Art, was appointed art master of the Victoria Institute, by a majority of nine votes over Mr. Roberts, of the Leicester Art School, who was recommended for appointment by the Library and Museum Committee.

The contractor for the new works of water supply now being constructed at Heckington for the Sleaford Rural Sanitary Authority is Mr. George Hay Williams, of Sleaford, not Williamson, as given in our issue of the 2nd inst, p. 151.

Legal.

STREET OR COURTYARD?

THE energy of the London County Council in the way of interfering with builders and building owners is as restless, and often as wrong-headed, as it is always costly to the unlucky ratepayers, upon whom fall the expenses of so much mistaken litigation. The latest instance of this is really striking in its complete unreasonableness, and we are glad to see that the Court of Queen's Bench in the case of "Wood v. London County Council" (*Times*, August 8) arrived at so plain and prompt a decision. The Council wanted to make out that, under section 7 of the New London Building Act 1894, an entirely private courtyard or quadrangle was a street within the meaning of that statute. The facts were simple enough. The appellant had pulled down an old brewhouse and stables called the Artillery Brewery in Victoria-street, Westminster, and he proposed to erect mansions to let in flats all round the sides of the square piece of ground. This quadrangle would be for the use of the tenants of the flats, their tradespeople, and visitors only. There would be no public right of way whatever. The entrance from Victoria-street was to be closed by lofty iron gates, and, in short, the courtyard was as private as if it had been the entrance to, say, Devonshire House.

However, somehow or other, the magistrate at Westminster decided as a fact that the place in question was a street, and he imposed a nominal fine, and stated a case. Of course, the point is of great practical importance, not only to this appellant, but to any other who may wish to make the most of so valuable a plot of land elsewhere. For if the London County Council were right, it would follow that the owner must give a 40ft. carriage drive and 20ft. footways for a courtyard, or quadrangle, for the private use of the tenants in the mansions round it, and so entirely spoil his place and render his scheme impossible. In truth, the main argument of counsel in support of the decision was that as the magistrate had found as a fact that this courtyard was a street, the Court could not go behind that finding, but must act accordingly. The Court, however, held that the magistrate was wrong, and that he was not entitled to find as a fact what the law did not allow to be a fact. The judges, again, declined to try and define what is a street; but they held that at all events this most private yard, shut in with gates, was not a street within the meaning of the Act.

Fred. Wetherfield, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

* * *

The trustees of the Leyton Wesleyan Church have accepted the estimate of Mr. C. F. Thompson, of the Burlington Joinery Works, Leyton, for the carrying out of certain alterations and additions. The work will be commenced at once. Mr. J. Williams Dunford, of 100c, Queen Victoria-street, E.C., is the architect.

An arbitration was opened on Tuesday at St. George's Hall, Liverpool, by Mr. J. Lawson Walton, Q.C., the arbitrator appointed by the Local Government Board, to determine the question of compensation between the corporation of that city and owners and other persons interested in insanitary property included in the 12th presentment under the Liverpool Sanitary Amendment Act, 1864. For the claimants, Messrs. Robert Wylie, Thomas Cook, and Mr. J. H. McGovern, architects and surveyors, of Liverpool, were called, and for the corporation Mr. William Wilson, of Manchester, Mr. Henry Hartley, of Liverpool, and Mr. H. P. Boulnois, the city engineer.

The new Post-office in Galashiels was recently opened. The Post-office has cost upwards of £5,000, and occupies a central position at the head of Channel-street. The building is of white sandstone, and the public room on the ground floor is 39ft. by 22ft., with the postmaster's room, telephone, silent room, and letter reception rooms at the side. In the back division, lighted from the roof, are the sorting-room, 49ft. by 34ft., the telegraph and telephone, male clerks, and message boys' rooms, telegraph stores, battery, and linesmen's rooms. The architect was Mr. W. W. Robertson, of Her Majesty's Board of Works, Edinburgh.

LEGAL INTELLIGENCE

Builder and Granite Merchant.—On Thursday, August 7, Mr. H. Harvey, of Falmouth, and Mr. Matthew Clemens, of Truro, with Mr. Stanley as umpire, acted as arbitrators, at Penryn Townhall, in the case of C. W. Andrews, granite merchant, Penryn, against J. G. Kelway, builder, Falmouth, about a dispute of a balance of account of £62 for granite supplied in the erection of a villa at Trefusis for Dr. Crossman. The case was referred from the High Court. It seemed that Mr. Kelway erected a villa at Trefusis in 1893 for Dr. Crossman. Mr. Andrew supplied the granite, and on the completion of the building defendant said he suffered damage owing to the irregular receipt of the stone, thereby causing extra work in shifting scaffolding. Plaintiff wrote to defendant that unless the balance was paid he could not send him further supplies for other work. For defendant it was contended that he complained to Mr. Andrew that the granite was sent in in an irregular manner, and not when required. Defendant was obliged to take £44 less than he was entitled to in building the residence, and felt justified in asking plaintiff to allow £9 in respect to time and labour lost in removing the scaffolding several times, the stone not coming in the right order. Evidence was given for defendants by N. Christopher and A. Rogers. The award will be made known in due course.

Bad Mortar.—At the Wolverhampton Police-court last week, John Pitt, Chetwynd-road, Villiers-street, Wolverhampton, was summoned, at the instance of the corporation, for having, contrary to the by-laws, used an unsuitable material as mortar in the erection of houses near to the Dudley-road. The town clerk stated that the corporation building inspector had taken a sample of what was being used as mortar by the defendant, and it had been analysed by the borough analyst, who certified that the stuff was not mortar, but mud, and totally unfit for use in building operations. As the alleged mortar contained vegetable matter, an unwholesome odour would be given off, and in time the dwelling would become uninhabitable. Evidence having been given of the sample of "mortar" having been taken, Eli Bird, bricklayer, Dudley-road, was called, and he stated that he did not believe any mortar was used on the date of the alleged offence. Defendant's solicitor put in the contract between Bird and Pitt, which showed that Bird was to be paid £198 to erect ten houses, and the defendant was to find the material. Bird expressed the opinion that the mortar was fairly good when it was ground again. The component parts were engine ashes, stone chippings, and a little soil. He described the mortar as good, and made with suitable materials. Mr. Jones, public analyst, said that the material submitted to him for analysis was mud, and not of the slightest value for building purposes. A fine of £5 and costs was imposed.

"Adamantine" Mortar—Messrs. Lawrence and Wildman, builders, of Prospect Cottage, High-road, Cricklewood, N.W., were summoned at Harlesden, on August 8, for erecting buildings at Church-road, Willesden, without causing the inclosure walls to be constructed with good mortar. The mortar used was said to have been made of mould and road-scrapings. For the defence a witness was called who said the mortar used by the defendants "set like adamant." The Bench thought the case thoroughly proved, and fined defendants £3 and costs.

Arbitration Appeal Judgment.—Cuninghame v. Richards.—This appeal was heard in the Court of Appeal of the Supreme Court of Judicature on July 22, before the Master of the Rolls, Lord Justice Kay, and Lord Justice A. L. Smith. Mr. T. D. S. Cuninghame, of Caldy Island, employed Mr. George Richards, builder, of Tenby, to execute alterations to his house upon the island, to build a landing-stage, and sundry other building works. When Mr. Richards's account was sent in, it was disputed by Mr. Cuninghame. After some negotiating it was decided by both parties to refer the matter to the arbitration of a London surveyor, and Mr. John B. Lofting, of 37, Old Queen-street, Westminster, was chosen as arbitrator. Upon his award being given, however, and it being higher than Mr. Richards's account by about £70, Mr. Cuninghame applied to have the award set aside. The application was heard in the Court of Queen's Bench, before Mr. Justice Wills and Mr. Justice Wright, and was granted, the award being set aside. Mr. George Richards, however, appealed against the decision of the learned judges when judgment was given. The Master of the Rolls: In this case a gentleman was altering his house, and also getting a jetty built, and there was the usual dispute between himself and the builder who did the work. It was agreed that the matter should be referred to a skilled architect and surveyor. To my mind he intended to intrust that man to do a great many things—perhaps almost the whole of what he had to do, according to his own knowledge and skill without any assistance at all. Mr. Cuninghame and his bailiff attended the arbitrator at times, and the builder also attended him, so that they both went before the arbitrator, individually, without all that assistance which they might have had if they had gone through the whole paraphernalia of the law. Then this skilled surveyor—who has all the prices before him, all the wages and works lists being laid before him—who can understand in ten minutes a great deal more than some legal arbitrator would understand at the end of a week's examination and long cross-examination, by puzzling questions, whether the prices are fair—he had not to decide in this case whether the prices were strictly accurate, but he had to say, trusting to his knowledge and experience, what was fair to be paid as between the building owner and the builder. The surveyor says he made some inquiries about the value of the work and what were the ordinary wages of such workmen as were employed in this locality. It seems to me that, so far from there being misconduct on the part of the arbitrator, he would have been doing a vast injury to both parties if he had done otherwise than he did. Then he sends his own clerk to measure and he takes his measurements, and his figures are produced in the presence of both parties and gone through by the surveyor. Then the surveyor takes away all the information he has obtained, and no one asks him to get more information and he makes his award, and then it is that Mr. Cuninghame is disgusted because he finds the amount of the award is so much larger than he thought it would be, and he could have settled for a very much lower sum. Then Mr. Cuninghame says this arbitration was not strictly or technically carried out, and he has persuaded two judges of the Divisional Court to say that it was not technically carried out, and that for an architect to ask what is the usual rate of wage for labour at a place like the one in question would be wrong, because it was done behind the backs of the parties. It was not done behind the backs of the parties—it was done as they agreed it should be done. The arbitrator heard what Mr. Cuninghame and Mr. Richards had to say, and I cannot see any misconduct on the part of the arbitrator at all. The astute lawyer says the arbitration was not technically carried out. What is fair is to say that there was no misconduct on the part of the arbitrator, and that Mr. Cuninghame is no worse off than anyone else who has a house built or altered. He finds that the bill is far larger than the estimate, and the next time he wants to build a house or a pier on his island he had better not trust to estimates, but have a firm contract. I cannot agree with the decision of the learned judges in the Divisional Court. I think they took far too technical and strict a view of the duties of this arbitrator, and that this appeal ought to be allowed; but the plaintiff has agreed to diminish the amount to be paid under the award to the amount which the builder sent in his bill for. I think, therefore, this bill should be allowed with costs. Lords Justices Kay and A. L. Smith concurring, an order was made that the appeal should be allowed, with costs, Mr. Richards undertaking not to enforce the award for more than £524, £800 having been paid.

In re H. Vulliamy.—Henry Vulliamy, architect, against whom a receiving order was made on the 4th ult., states that he first commenced business about the year 1870 in Abchurch-lane, City, with little or no capital. In April, 1879, when in business at 122, Newgate-street, E.C., he was adjudged bankrupt in the London Bankruptcy Court. The liabilities were £3,359, and the assets *nil*. A scheme of arrangement was accepted by the creditors, whereby the debtor paid to the trustee in the proceedings the sum of £350, and the bankruptcy was annulled. The Official Receiver states that it does not appear from the file of proceedings whether or not any dividend was paid to the creditors. The debtor asserts that this failure was caused through liabilities incurred by him for goods supplied to a builder, who disappeared, and he was called upon to pay. He further states that for three years immediately preceding the date of the present receiving order he carried on business at 32, Lawrence-lane, Cheapside, E.C. The accounts show liabilities £11,585, of which £1,714 are unsecured, with assets £325. The debtor attributes his present insolvency to liabilities on guarantees and acceptances for which he received no consideration.

A Bill of Exchange Case.—Price, Walker, and Co., Limited, v. Webb.—At the Birmingham Assizes, on the 8th inst., before Mr. Justice Charles, sitting without a jury, Messrs. Price, Walker, and Co., Limited, timber merchants, Gloucester, brought an action against Daniel Webb, a glass merchant, of Birmingham, respecting five bills of exchange endorsed by the defendant and dishonoured. The bills of exchange were one for £57 14s. 6d., one for £45, and three for £50. The plaintiffs had customers in Birmingham named Fairbank and Co., who were also timber merchants. Fairbanks had a customer named Austin, a builder and contractor, in Birmingham, to whom they declined to give further credit unless some arrangements were made for a guarantee. As a result of this refusal, it was arranged that the defendant Webb should countersign the orders. The bills were given in part-payment of a debt to Fairbanks by Austin. They were drawn by Webb, and accepted by Austin. Fairbanks were customers of the plaintiffs, and paid the bills over to them, credit being given for them. The bills were ultimately dishonoured. Evidence in support of this was given by Mr. Fairbank and his clerk, it being admitted concerning one of the notices of dishonour that the notice had not been sent until some days after it was due, although it bore the proper date. Fairbank also admitted making false statements in a letter to Mr. Webb respecting the bills, with the object of obtaining payment. Fairbank's clerk also admitted that he attempted on one occasion to carry off documents belonging to the estate of Austin. Commenting on the evidence, his Lordship remarked that on no fewer than three occasions Fairbank had admitted things in reference to the case which were not creditable to him. The defence was that the first bill had been satisfied and discharged, and that with respect to the others defendant did not receive notice of dishonour; further, that they were endorsed without consideration.—In giving judgment, his Lordship said a most reprehensible piece of trickery, it seemed to him, was practised by Fairbank with reference to the bills. He not only told falsehoods, but he positively manufactured a bogus notice of dishonour. With regard to the question of law, he was of opinion that there had not been a notice of dishonour; but the defendant's conduct, he thought, had been such as to become a waiver of the notice of dishonour. He must therefore give judgment for the plaintiff in respect of each of the bills, except the first one, which had been paid.—Mr. Lawrence stated that after allowing for the first bill the total claim was £195.

CHIPS.

M. Hanotaux, French Minister of Foreign Affairs, has taken the initiative in the organisation of a Diplomatic Museum in one of the salons of the Quai d'Orsay. It is proposed to exhibit commemorative medals, seals, original documents, and portraits of diplomatists who have played prominent parts in the settlement of important international questions. M. Hanotaux has already collected a considerable number of historical curiosities, and a few portraits of diplomatists.

Colonel Campbell Walker, Indian Staff Corps (retired), formerly Chief Conservator of Forests, Madras, has been offered and accepted the appointment of Inspector-General of Forests to the Government of Mysore, and will leave England shortly to take up the duties.

At a meeting of Glasgow Established Presbytery, on Friday, it was reported that of the £10,022 required for the erection of the church at Titwood, £8,728 had been subscribed.

The dedication and formal opening of the grand new organ presented to the parish church at Epping by Mr. and Mrs. E. J. Wythes, of Copped Hall, took place on Thursday in last week. The organ, said to be the largest in Essex, was constructed by Messrs. Wordsworth and Co., of Leeds. It consists of four manuals and separate pedal organ; there are four rows of keys besides the pedals. The bellows are driven by a gas-engine, placed in chambers built specially for the purpose by Messrs. Rudd and Son, of Grantham, below the church. There are 2,344 pipes in the instrument, and 51 draw stops. A carved oak case with silvered pipes, designed by Kemp, of London, will shortly be erected.

At the quarterly meeting of the Shrewsbury town council on Monday, the sanitary committee reported that they had had an interview with Mr. J. S. Phillips, the owner of the Monkmoor estate, with the view of purchasing it for a sewage farm. The estate consisted of 172½ acres, with a residence, farmhouse, buildings, and three cottages, and Mr. Phillips was willing to sell the whole for £22,500, including law costs. The committee asked authority to enter into a contract with Mr. Phillips for the purchase of the property. Several members thought the price, £125 per acre, too high, and after considering the matter in committee, the council decided to make a lower offer.

The permanent collection in the Walker Art Gallery, at Liverpool, has received the addition of a picture stated to be by Guido Reni (1575-1642), representing "The Death of Lucretia." The work is the gift of Mrs. Harriet Bostock, Onslow-gardens, London, and shows the Roman heroine about to terminate her life with a dagger.

Mr. G. Miners, of Marazion, has secured the contract for the erection of a Workmen's Institute at Gulval, near Penzance, which is being given by Mr. R. F. Bolitho, and also for the rebuilding of the Old Inn and cottages at the same place. Mr. W. H. Trounson, of Penzance, is the contractor for the workmen's cottages which Mr. Bolitho is also erecting at Gulval. Plans for the whole were drawn by Mr. Oliver Caldwell, F.R.I.B.A., of Penzance.

WATER SUPPLY AND SANITARY MATTERS.

Baildon, near Bradford.—On Saturday the members of the Baildon District Council officially inspected their new reservoir, the work of construction having been now completed, with the exception of trimming the embankment and other trifling features. The undertaking has been a costly one, and the actual operations were begun in June, 1891. The reservoir, in connection with the rest of the council's waterworks system, is calculated to meet the requirements of the district for the next thirty years. In 1854 there was only one reservoir of 500,000 gallons capacity, and two further reservoirs were added, placing the district in the possession of a total storage capacity of 9,000,000 gallons. These three basins, which are situated on Baildon Moor, entailed a cost of £6,000. The area of land, on the edge of Rombald's Moor, and at a place comprised in Hawksworth Moor, covered by the fourth reservoir now completed and margin land, is 21 acres, of which the basin itself, at the top water level, measures eight acres. The reservoir is some 800ft. to 1,130ft. above the sea-level. The reservoir embankment is about 50ft. at its highest part, and the greatest depth of water will be some 30ft. The cost has been about £30,000.

Ipswich.—Col. John Ord Hasted, R E., one of the Inspectors of the Local Government Board, held an inquiry in the Council Chamber, Town Hall, Ipswich, on Thursday in last week, in reference to an application by the Corporation of that borough for sanction to borrow £14,500 for works of sewerage at St. Mary Stoke, and £2,400 for a new street through Orwell-courts from Eagle-street to St. Helen's-street. Evidence was given by the borough surveyor, Mr. E. Buckham, and Mr. I. Shone, of Messrs. Shone and Ault, the engineers for the system of dealing with the sewage of Stoke. It was explained that the Stoke sewerage proposed is the second moiety of a scheme for draining at one and the same time the Marsh and Stoke districts. That portion which dealt with the Marsh district has already received the approval of the Local Government Board, and the compressed air required to work the ejectors in Stoke will be provided at the same station as that required for the ejectors in the Marsh district. The sewage of Stoke will be ejected into the present main intercepting sewer, and will also pass along it, and out at the existing outfall. Only sewage proper will go into the main sewer, as provision will be made for taking storm-water direct into the river. The sewage of the Stoke district will be led to a station at the end of the road known as New Cut West, and thence passed over Stoke Bridge and into the main intercepting sewer at St. Peter's Church corner. The drainage of the Marsh district is complete in itself; that district is divided into two drainage areas, in each of which is an ejector station, and the sewage is to be passed into the main sewer. That work is now in progress. The compressed-air main for operating the ejectors on the Stoke side will go from the central station by Russell-road and Commercial-road over Stoke Bridge. The Stoke district is divided into three drainage districts.

* * *

Mr. Marshall, at present a surveyor under the Norfolk County Council, has been elected surveyor to the rural district council of Malling, Kent.

The foundation-stone of new Wesleyan schools and vestries, at Bill Quay, near Newcastle-upon-Tyne, were laid on Saturday. The buildings will cost £1,700, and are the first portion of a scheme to include a new chapel at a further cost of £2,300. Mr. J. W. Taylor, F.R.I B.A., of Newcastle, is the architect, and Mr. Robert Allison, of Whitburn, the sole contractor. The style is Early English, and the facing material Heworth stone.

Colonel Langton Coke, one of the inspectors of the Local Government Board, held an inquiry at the Court-house, Warwick, on Monday, with reference to an application of the town council for a loan of £1,100 for works of water supply. The town clerk explained that the severe frost in January and February last had burst 4,000 yards of water-mains in thirty-five streets in the borough. It was proposed to lay new mains at a greater depth. The borough surveyor, Mr. Melville Richards, gave particulars of the scheme.

Burnley's second public park was formally opened and handed over to the town on Friday. It will be known as the Scott Park, and is the outcome of a generous bequest by the late Alderman John Hargreaves Scott, who died in 1881. Mr. Scott, who was twice Mayor of Burnley, bequeathed practically the whole of his fortune for the purpose of a park, stipulating that the area should not exceed twenty acres. The trustees secured an admirable site on the Hoodhouse estate, and comprising about eighteen acres. The land is beautifully wooded, and a stream flows through the centre of the park, and adds very considerably to its embellishment. Some £16,000 or £17,000 has been expended by the trustees.

Our Office Table.

The Scottish Board of Manufactures have just made an interesting addition to the collection in the Scottish National Gallery, at Edinburgh, by the acquisition of "The Abbotsford Family," painted by Sir David Wilkie in 1827, and well known from the engraving by Robert Graves, A.R A. It represents the Scott family in peasant costume grouped on the terrace near Kayside, commanding a view of the Eildon Hills. Though only of cabinet size, the portraits are painted with remarkable finish. The picture, which is in an excellent state of preservation, was hung at the Scott Exhibition held in Edinburgh in 1871 to celebrate the centenary of the birth of Sir Walter Scott, and it was also shown at the Loan Exhibition of 1884 as the property of Mrs. Admiral Ferguson. The picture was executed for Sir Adam Ferguson, whose portrait is the most successful in the group. It is understood that the Board of Manufactures purchased the work for 800 guineas.

The electric-light works of the Salford Corporation, situated in Walness-road, Lower Broughton, were formally opened on Wednesday week. The amount actually expended to the present time has been £29,206, and the balances due to the various contractors on the expiration of the period of maintenance will increase the expenditure to £34,338. The committee engaged Messrs. Kincaid, Waller, and Manville, electrical engineers, of Great George-street, Westminster, to devise a scheme of supply, and prepare the necessary drawings and specifications. The committee have adopted the high-pressure alternating system, by which the current is supplied at a pressure of 3,000 volts, through concentric copper cables, insulated with special impregnated fibrous compound, laid in cast-iron pipes. This pressure is reduced by transformers at consumers' premises to about 100 volts. There are three sets of engines and dynamos at the generating station, each set capable of supplying 2,500 8-candle power lamps alight at one time, or to 2,800 lamps connected to the mains, it being found that only about 60 per cent. of the lamps connected are alight at the same time. The producing power of the station is equal to supplying 8,300 8-candle power lamps, connected to the mains. The cables have been constructed to supply 17,000 8-candle power lamps. The buildings were erected by Mr. Samuel Warburton, of Manchester, for the sum of £6,600. There are three sets of slow-speed horizontal compound condensing engines of 200N.H.P. each; these were supplied by Messrs. Browett, Lindley, and Co., of Patricroft, at a cost of £4,309. The dynamos and exciters were supplied by Messrs. Mather and Platt, Limited, of Salford, and are driven at the rate of 500 revolutions per minute. Messrs. Mather and Platt also supplied the switchboard and electrical instruments, the total amount of their contract being £3,150. There are three Lancashire steel boilers, fitted with mechanical stoking appliances and economisers; these were supplied by Messrs. Tinkers, Limited, Hyde, at a cost of £3,704. The mains are laid in three circuits, and the charge for current is now 7d. per unit.

Our Transatlantic brethren have not been backward in devising churches with large central areas. A plan of a new church (Holy Trinity), Harlem, New York, is given in the *Scientific American*, Building Edition. The plan is a Greek cross, with short arms, the central area of crossing being a square of 50ft., and the roof is a groined plastered vault with moulded arches and ribs, and each transept has a tunnel-vault. Galleries are provided in the transepts. The chancel is a five-sided apse covered by a semi-dome, the wall of apse is wainscoted in African marble, with oak panelling over, and is said to be impressive. The seating capacity is twelve hundred. The bishop's throne is placed in the apse behind the altar table, which stands in front of it—a recurrence to the old Basilican plan.

The annual summer meeting of the Institution of Junior Engineers, whose headquarters are in London, takes place from August 17 to 24, the rendezvous being Belgium. The towns to be visited include Antwerp, where the municipal docks, M. Kryn's diamond-cutting works, and other places of interest will be opened to members' inspection. At Ghent, MM. Carel's engine works, M. de Hemptinne's cotton-spinning works, and M. van Houtte's nursery gardens will be seen; at Brussels, the electric-lighting station; whilst at Liège the works of the Société Cockerill, the Vieille Montagne Zinc Works, the St. Leonard Locomotive Works, the Val St. Lambert Glass Works, the Small Arms Factory, and the electric tramway installation will be visited. In honour of the institution, a banquet is to be given by the Liège section of the Society of Engineers from the University, and the members will also be the guests of the Société Cockerill. An excursion to Verviers, where the Chamber of Commerce will entertain the visitors, is arranged, for the purpose of seeing works in connection with the woollen cloth industry. Here MM. Peltzer's works, and those of M. Duesberg-Debrez, La Vesdre, and M. Hauzeur Gerard *fils* will be opened. The celebrated Gileppe Reservoir, from which Verviers receives its domestic and manufacturing supply, is also included in the programme. A large number of members have notified their intention of being present at the meeting, which promises to be one of the most successful the institution has held.

The excavating action of water-jets in sinking caissons for foundations is well known. An improved mode of sinking open steel cylinders is described in the *Scientific American*. It consists in forming round the bottom edge of the cylinders a series of water-jets issuing from hollow castings—the lower edge of the castings is made sharp as a cutting edge. The water is forced down to the jet openings through pipes on the inner edge of the cylinder, these being connected by flexible tubes to valves in the main supply-pipe from the pump. As the cylinders are sunk other segments are added. The top of the cylinder is weighted by brick or stone, which assists the descent. The water-jets round the cutting-edge at the bottom wash out the soil, and, rising up the surfaces of cylinder, lubricate them and assist the operation. The jets round the bottom can be manipulated at will by the valves, so that any hard ground on one side can be operated on by opening the jets on that side so as to clear the obstacle. The method described is a simple one, and the cylinders are rapidly sunk.

The annual meeting and two days' excursion of the Cumberland and Westmoreland Antiquarian and Archæological Society took place on Thursday and Friday. The members and their friends met at Carlisle, on Thursday, for the purpose of visiting the remains of the Roman Wall in Cumberland. Proceeding by train to Gilsland, the camps at Bird Oswald and Appletree were visited, the president, Chancellor Ferguson, describing the excavations about to be commenced at the latter station. At Lanercost Priory papers were read by Professor Pelham, F.S.A., of Oxford, on "The Roman Frontier System"; by Sir James Ramsay, Bart., on "The Roman Wall"; by Dr. Barnes, of Carlisle, on "The Proposed Ethnographical Survey"; and by Mr. C. J. Ferguson, on "Carlisle Cathedral." The latter paper explained all the discoveries made during the past three years of the foundations of an eastern apse on each of the transepts. On Friday, the members proceeded by train to Brampton, and after visiting Castlestairs, followed the course of the Roman Wall to Carlisle, and on to Burgh Marsh.

A meeting of twenty-three members of the Scottish Building Trades Federation, representative of the principal towns in Scotland, was held on Tuesday afternoon at 5, St. Andrew-square, Edinburgh—Bailie Selkirk, Glasgow, presiding—when a constitution and rules were formally adopted, and office-bearers were elected. The objects of the Federation, which is composed of employers only, are (1) to encourage, by friendly conference and otherwise, the maintenance of cordial relations between employers and operatives in the building trades, and the satisfactory adjustment of all differences arising from time to time; (2) to secure united action in dealing with demands made by workmen in reference to wages, hours of labour, piecework, overtime, employment of non-union men, apprentices, use of machinery, and generally all restrictive conditions sought to be imposed upon the building trades; (3) to assist, as far as practicable, local associations in time of strikes and on other fitting occasions by such means as may be considered desirable; (4) to secure the recognition by architects, measurers, and others of a fair and reasonable form of contract between contractors and their customers, and to further the adoption, in the building trades, of suitable rules for measuring work, and the adjustment of contractors' accounts;

and (5) to establish branches of the Federation in towns and districts throughout Scotland, and render them suitable advice and assistance as required. Mr. David Heron, Edinburgh, was elected president for the current year, and Mr. John Adam, Glasgow, and Mr. J. B. Hay, Dundee, vice-presidents. An executive of twenty-one members was also appointed.

MEETINGS FOR THE ENSUING WEEK.

Saturday (To-morrow). — London and Provincial Builders' Foremen's Association. Annual Dinner at the Four Swans, Waltham Holy Cross. 4.15 p.m.

A bazaar has been held at Flamborough to provide funds for rebuilding the tower of the parish church, destroyed more than 230 years ago. The plans and specifications for the proposed new tower have been prepared by Mr. C. Hodgson Fowler, F.S.A., of Durham. The estimated cost is £1,000, and of this amount £600 has been subscribed.

The Perth builders had their 21st annual outing on Wednesday last. The trip this year consisted of a drive to Crieff viâ Methven and back by Muthill and Auchterarder. This year the numbers were considerably smaller than usual. At Crieff, dinner was served in the Commercial Hotel. Mr. A. Beveridge, builder, the president of the association, occupied the chair.

The August report of the Amalgamated Society of Carpenters and Joiners contains the following notice to members: "As it is extremely probable that the building trades in the London district will be frequently in conflict with employers for the maintenance of existing working rules, all members are earnestly requested to keep away."

The Sittingbourne Urban District Council have resolved to accept the tender of Messrs. Calvert, Harris, and Co., of London, for two engines and the necessary pumps and fittings, recently in use at the Guernsey Waterworks. The engines, which are to cost £2,065, will be put down at the Sittingbourne Waterworks, and a new reservoir, capable of storing 300,000gals., is about to be constructed.

The War Office are about to demolish the Citadel at Plymouth and reconstruct it as a large artillery depot. The tender has been accepted for the first section, which includes the demolition of the old magazines, and the erection of a mess block for 17 offices, at a cost of £50,000. This portion of the scheme is to be completed by May, 1897. The second section is to be commenced next year, and includes the demolition of the present married quarters, and the building of an extensive drill quadrangle.

The Grand Prix de Rome for this year has been awarded to M. Gaston Larée, a pupil of M Bounat, for his work representing "The Holy Women at the Foot of the Cross." The second Prix de Rome has fallen to M. Albert Laurens, son of the artist, J. P. Laurens, and a pupil of Benjamin Constant and M. Cormon.

A sanatorium, which has been erected by the Cardiff Corporation at Canton, at a cost of about £37,000, was formally opened by the mayor of that town on Friday.

Mr. D. W. Barker, founder of the firm of Barker and Co., of the Worcester Patent Brickworks, and managing director of the company which recently acquired the business, died at Worcester on Friday.

The Wolverhampton town council accepted, on Monday, an oil painting of the late Alderman Edwards in his mayoral robes and chain, to be hung in the council chamber.

At Cockermouth, a park given to the town by Mrs. Harris, of Derwent Bank, was opened on the 8th inst. The park, which is situated near the railway station, and is bounded on one side by the river Cocker, is 12½ acres in extent. It is beautifully wooded, with natural walks, and commands views of lake scenery on one hand, and of the Scotch hills and the Derwent valley on the other. About £500 has been expended in laying out the grounds, a bowling-green, gymnasium, and a children's shelter being among the adjuncts provided.

At an investiture held by the Queen at Osborne on Monday, her Majesty personally invested Mr. John Taylor, F.R.I.B.A., surveyor to H.M. Office of Works, and Major Henry Pilkington, director of engineering and architectural works at the Admiralty, with the insignia of Companions of the Order of the Bath.

The work of restoring Curdworth Church, Warwickshire, is now going on. It has been undertaken by Lord Norton, who is a joint patron of the living. The restoration involves to a large extent rebuilding, and the expenditure to which Lord Norton has committed himself—as a thankoffering to God on entering the ninth decade of his life in health and strength—is £15,000.

Trade News.

WAGES MOVEMENTS.

Building Trades Federation.—At the invitation of the London Building Trades Federation a preliminary conference has been held at the Operative Bricklayers' Hall, Southwark Bridge-road, for the purpose of consolidating the various building federations throughout the country. The business resolved itself into the consideration of suggested rules for the National Federation, which were ultimately agreed to by the delegates, and ordered to be sent to the various federations throughout the country for their ratification. By means of this National Federation, over 70,000 organised building workers will join hands in defence of trade interests.

Dundee.—At the present time an agitation is going on amongst the operative masons in Dundee for an increase in their wages. According to the statements of the men a good deal of work is going on in the city and district, and they have opened negotiations with the masters with the object of having the wages of builders raised from 8½d. to 9½d., and that of hewers from 8d. to 9d. The communications of the men have since been considered by a meeting of the masters, who, while expressing no opinion on the merits of the case, have invited the men to confer with them on the question.

CHIPS.

New schools are being built for the School Board for St. George, near Bristol, from designs by Mr. Mackay, of Kingswood. They occupy a prominent position just off the main road at Two Mile Hill.

The monthly report of the Labour Department, issued yesterday (Thursday), states that the building trades, on the whole, continue busy, and the percentage of unemployed in Union, making returns has fallen from 2·5 in June to 2·4 in July, compared with 3·6 in July last year. The furnishing and woodworking trades have fallen off to some extent, the percentage of unemployed Union members having risen from 2·4 in June to 3·0 in July, compared with 4·4 in July, 1894.

The South Staffordshire Mines Drainage Commissioners, at a special meeting held at Dudley on Wednesday, approved of a scheme, prepared by Mr. Howell, the engineer, by which it is hoped to clear the water in 11,000 acres of mines in the Tipton district. New pumping-engines of the most approved type are to be laid down, also hydraulic engines connected with a ten-mile circuit of piping. These, it is estimated, will raise 12,000,000 gallons of water daily.

Mr. Wolfe Brennan, C.E., has begun the survey of the proposed railway line to connect Loch Fyne with the West Highland Railway system.

The urban district council of Weston-super-Mare are seeking to keep abreast of the times and to provide additional attractions for the visitors. With this object in view, they have been negotiating for the purchase of the Knightstone estate for £12,000, and last week they decided to seek for powers to erect a new pavilion, to construct two marine lakes and a low-water pier in connection with and adjoining the Knightstone property. An engineer is to be employed to consult with the council upon these matters.

The marble bust of the late Mr. Christopher Thomas, which has been presented to Bristol, was unveiled at the Council House in that city on Wednesday afternoon. The bust is from the studio of Mr. Tom R Essex, of Devonshire-street, Portland-place, London. A silver tablet affixed to the pedestal sets forth that he was a member of the Bristol town council for 39 years, from 1845 to 1893, and was mayor in 1874-5.

The late Mr. George Jacques, Spring Bank, Silsden, instructed Messrs. W. Potts and Sons, clock manufacturers, of Leeds and Newcastle-on-Tyne, to place a new Cambridge quarter clock, with four illuminated dials, in the tower of the parish church of Silsden, near Keighley; but having died before completion, Mr. Jacques' family have carried out the project. Messrs. Potts also made and fixed the Prince Smith Memorial, Keighley, and the Haggas Memorial Clock, Ingrow, near Keighley.

Professor Herkomer has consented to open the exhibition of the South Wales Art Society in Cardiff on October 5th. The society has secured the premises of the Glamorgan Club, opposite the Taff Vale Railway offices, for its permanent home, and these will be adapted to the requirements of the society in due course. The formal opening of the building on October 5th by Professor Herkomer will be an auspicious event in local art circles, and will undoubtedly give a deserved filip to the society and its work. The professor is one of the vice-presidents of the society, and sent a fine portrait of Archibald Forbes to last year's exhibition.

At the last meeting of the Manchester city council, it was announced that the purchase of Chat Moss for the purposes of the cleansing committee had been completed, and would meet the requirements of the city probably for fifty years. The area purchased was 2,594 acres, and the total cost to the corporation was £147,631.

A rectory is about to be built at Sheldon, near Honiton, from plans by Mr. E. H. Harbottle, of Exeter.

A new secondary school at Mavisbank, which has been erected by the Airdrie School Board as a higher department of Airdrie Academy, was formally opened on Tuesday by Mr. James A. Campbell, LL.D., M.P. The main block is a building 85ft. by 59ft., and of two stories in height. There are separate entrances for boys and girls. The elementary education accommodation is confined to the ground floor, while the Science and Art department is to be accommodated on the upper floor, and consist of a complete chemical laboratory, balance room, instrument-room, mechanical drawing-room, and cast-room, while provision is made in detached buildings for the teaching of cookery, laundry work, and for modelling. Provost Aitken is the architect of the building.

The recumbent bronze effigy of the late Bishop Harvey Goodwin, designed and executed by Mr. Hamo Thornycroft, R.A., will be unveiled in Carlisle Cathedral by the Archbishop of York on September 17.

The new "Forster" Board Schools, built by the Cowpen U.D. School Board, were publicly opened on Tuesday. The schools are built on a site half an acre in extent, in Hambledon-street, on a portion of the Thornton Croft estate. They are two stories in height, and consist on the ground floor of an infants' department, and on the first floor of a mixed elementary school, with a total accommodation for 650 children. The exterior walls are of deep red brick work, with red terracotta strings and dressings to gables and doorways. The contract, amounting to about £4,000, has been carried out by Messrs. H. Brown and Co., of Newcastle-on-Tyne, from the designs of Mr. J. H. Morton, F.R.I.B.A., of South Shields.

In New York there are signs of approaching activity in the building trade. The number of permits for the erection of new buildings during the past six months is almost exactly twice as great as the number issued during the corresponding part of 1894, and the proportion between the intended cost of the buildings for the two periods follows nearly the same ratio. Meanwhile, the number of permits for alterations has not very much increased.

The annual meeting of the Bristol and Gloucestershire Archæological Society was held on Tuesday at Berkeley. After a general meeting of the members at the Town-hall, luncheon was served at the Berkeley Arms Hotel, followed by a visit to Berkeley Castle, under the guidance of the Rev. W. Bazeley, general secretary of the society. The members were entertained at tea in the gardens of the castle by Lord and Lady Fitzhardinge, and in the evening they attended a conversazione at the Town-hall. On Wednesday Berkeley parish church was inspected, after which the party proceeded in brakes to Wanswell Court, the ancient residence of the Thorpe family, and thence to Bradstone, the home for many centuries of the Bradstone family, North Nibley, and Wotton-under-Edge. The excursions yesterday (Thursday) were to Stone, Tortworth, and Thornebury church and castle.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2120.

FRIDAY, AUGUST 23, 1895.

RECENT "CENTRAL AREA" DESIGNS.

WE briefly referred, last week, to the erection of another church in New York on a "central area" plan. A Congregational chapel, on rather similar lines, was recently opened at West Hampstead; and another, almost identical with it in idea, if not in style, was built some time ago at Wigan. These two adopt the familiar form of an octagon, with arms radiating from its cardinal faces—a form which was cleverly treated five-and-thirty years ago by Messrs. Lanyon and Lynn, in their design for Trinity Church, Edinburgh. This, when compared with its recent imitations, shows that the central area idea, like others, depends for its success on the skill and inventiveness with which it is applied. There is much to be made out of it, for certain special purposes; but the making requires a maker. It is not a mere trick, or formula, or recipe, which anyone can follow with the certainty of success; on the contrary, it presents the thoughtful architect with a great many problems, some of which are by no means solved as yet.

Nobody suggests—nobody, as far as we know, ever did suggest—that a central area plan is desirable for all sorts of public buildings, or even for all sorts of churches. Where people go to church simply for the purpose of worship the types of plan which have been handed down by custom and tradition need no radical change. Their own beauty and the associations connected with them will keep them in use, as they ought to do. But there are persons—some in the Church of England, and many more outside it—who are never satisfied without hearing a sermon. Perhaps they are not always of the most intelligent class, but they have to be provided for. On weekdays they do not read much, except their newspaper. Reading, possibly, is little to their taste. What they find to be easier, and like better, is to sit in a comfortable seat and listen to a discourse of moderate length. Like Parson Adams, they think that "no one can have his duty too frequently inculcated into him." So they attend services, and bring others to attend them, and feel that they are receiving good and doing good, provided always that they can hear distinctly what is being said to them. It is mainly, though, people of this class, and the preachers that address them, who find the ancient types of church inconvenient. The architect who works for them may or may not share in their passion for being preached to; but it is his business to provide them with buildings in which sermons can be heard, and heard, in some instances, by very large congregations. If he has anything of the artist about him, he tries to do this in an architectonic way, and not by merely substituting thin iron props for stone nave-piers, as the manner of some is. Towards this architectonic mode of dealing with the problem, the central area idea may help him, if, and only if, he knows how to use it.

The simplest form of central area is a square. And when a building is without columns, a square will obviously hold more people than an octagon of the same diameter. For the sake of acoustics, too, as well as of accommodations, it is often better to retain the square plan nearly up to the roof-level, and to let the octagon, if an octagon is wanted, start from above the heads of the congregation. There is a picturesque specimen of this treatment in Sir A. Blomfield's little church for the deaf and dumb, St. Saviour's, Oxford-street. There is an example of it on the great scale at Sta. Maria delle Grazie, Milan, where the square finishes outside as a many-sided polygon. Both these have a projecting choir and shallow transepts. We illustrated, on November 10, 1893, a Jewish synagogue at Buffalo, N.Y., in which the lower stage is a square without transepts brought into an octagon higher up by diagonal arches. Messrs. Kent are the architects for this interesting and original work. If it has little of what a European recognises as beauty, it has a large amount of character and individuality. There is a certain suggestion of Eastern tastes about it; a sort of exclusiveness and separateness which seem to fit it for a race who, if they are in the Western world, are not really of it. It has small windows, unbroken masses of masonry, rounded corners with domed turrets, and a great rounded dome by way of roof. The details, of which there are few, are Saracenic in character. But there is nothing of the lightness and elegance of Arab or Persian architecture in the design. It has a sort of grim solemnity, not adapted, any more than it is intended, to bring in the Gentile and the stranger.

This is not at all the sort of thing that a chapel committee would choose. Their aim is not to repel, but to invite, and their idea of art is that it should be "an attraction." If it were really art which they employed for this end, we might overlook the motive for the sake of the result. But we all know how seldom this happens. To pile on the cheapest of cheap finery is their general practice, and the architect who can produce the flashiest chapel at the lowest price is the one who gets commission after commision. The central area type, which ten or fifteen years ago seemed to show such people a possibility of better things, is being vulgarised like the rest, and we are learning how hard it is to do good work for clients who like bad work better.

There is no particular advantage in that crudest of all central area forms—a mere octagon, without columns or transepts. By itself it does not seat a congregation to the best advantage, and it involves much danger of echo and reverberation. Yet every now and then some architect—it is to be hoped a young and inexperienced one—builds a chapel of this shape, which is duly announced as a great original invention. But it is not, strictly speaking, a "central area" building at all. A central area is a large open space in the middle of an edifice—a space, that is, with other spaces round it. St. Paul's, for instance, has a central area. St. Stephen's, Walbrook, has another. The Duomo of Florence has a third. Each of these possesses a great unbroken space in front of the choir, with aisles, avenues, transepts, or recesses of other kinds opening into this space. The junction of this space, whether it is square, polygonal, or circular, with these appendages, leads to a great deal of interesting planning, and gives opportunities, amongst other things, for inserting galleries, so as to make them picturesque instead of offensive. Indeed, it is the great merit of the central area system, for congregational purposes, that it does facilitate the artistic treatment of galleries. They are a necessity where a large audience has to be arranged for. They are an unavoidable part of any structure erected for the "popular preacher" of modern times, because no man can long make himself audible to several thousand people, unless they are grouped more closely round him than they can be on a single floor. But we may note in passing that the "popular preacher," or, indeed, the orator of any kind, does not like his audience cut up into a lot of little bits. He objects to a number of separate galleries, each holding its own small group, perhaps, of 50 or 100, away from the other galleries, and from the general mass. He likes one large congregation—not five or ten small ones.

This principle seems to have been borne in mind in the design of the New Synagogue at Berlin, erected not long since by Messrs. Cremer and Wolffenstein. It seats 800 men on the ground floor, and 800 women in the galleries, and has cost £41,000. In general arrangement it closely resembles Union Chapel, Islington, which we illustrated some sixteen years ago. The central area is of the same shape—namely, a square, with the corners cut off—and is a few feet less in diameter than in the English example. A stone pier at each of the eight angles carries moulded arches, alternately wide and narrow in span. The gallery, whose front rests on segmental stone arches, surrounds the central space, and an upper gallery runs straight across one end of the building, above the lower one. This, judging from the views, interferes greatly with the effect, and looks like an attempt to crowd in more people than the design is really fit for. Probably the architects were the last persons who desired this addition; but the "practical man" seems to be as rampant in Berlin as he is here. Perhaps it is to him, too, that we owe the continuing of the gallery into what, in a church, would be the choir. This takes off considerably from the symmetry of the interior, and gives a weak appearance to what should have been the strongest-looking of all the piers. The whole gallery, moreover, is much too heavy, and too ornate. It attracts attention as the main feature of the design, and quite overpowers the arches and vaults above it. The style generally is a kind of Early Gothic.

Of course the central area type need not be, and has not been, confined to religious structures. It appeared as a twelve-sided polygon, 100ft. wide, in Mr. Collcutt's design for the South Kensington Museum. In an imperfect form it exists in most theatres and in some concert-halls. In all such cases the gallery problem goes along with it. Theatres, commonly, are innocent of any attempts to solve it; perhaps the theatre architect has never yet discovered its existence. Perhaps, on the other hand, he is too hardly pressed by the "practical man," in the shape of the manager or the lessee, to whom one more seat means from £20 to £50 a year, and who would turn a deaf ear to all the arts together if they tried for a moment to prevent him from getting it. So between chapels and theatres and synagogues the central-area idea is rather in a hard case. Architects might develop it much further, and carry it to much greater perfection; but the primary difficulty is to educate their clients.

◆

DETERIORATION OF TOWN DWELLINGS.

JUST now a great deal of attention is being directed to sanitary dwellings in large towns. A vast addition to the number of smaller houses and tenements is made every year, with the result that attention to good construction and sanitary precautions depends greatly on the efficacy of administration. The British Institute of Public Health Congress at Hull has been discussing, among other matters, the wholesale manner in which insanitary houses had been closed in Sunderland by the sanitary authority, owing to the system which prevailed of back-to-back houses. The refuse of these houses had to be brought through the houses, often through the bedrooms. Happily this state of things exists only in a few of the towns. Amongst these Halifax is one of the principal. According to D. Barry and Mr. P. Gordon Smith's Report on "Back-to-Back" Houses, published in 1888, the percentage of houses built on this plan was considerable. But here the discretionary powers of the sanitary authority have been exercised of late years. One of the by-laws states that it shall not be lawful for any person, without the consent of the corporation, to erect dwelling-houses in blocks, so that any block shall contain more than eight dwelling-houses when built back to back. These blocks are shown 34ft. deep, with streets of 30ft. between, and about 56 houses to the acre can be built on this plan. At Keighley, the blocks are confined to four houses. An improved arrangement for "through" houses in continuous rows is provided for by the model by-laws, having a back street of 10ft. wide to give access to the privies and ashpits. We hope before long to see the system of back-to-back houses entirely superseded by the arrangement of "through" houses, having access for the removal of refuse. For this and other abuses we have generally looked to individual ownership as the remedy; but there are others who think differently.

Mr. William Stevenson, of Leith, in a lecture on "Uninhabitable Houses in City Slums," given in the *Engineering Magazine*, discusses the question from experience, and throws some light on the advantage or otherwise of the proposal "that the best guarantee that the home of the working man shall be comfortable and healthy is that he shall be owner of his own dwelling." The conclusion drawn is that the proposal is a fallacy, and will not bear investigation, and the author points to the houses in Edinburgh and Leith, in which this system has contributed to make them unhealthy and uninhabitable. Several reasons are given for this conclusion which may be referred to. The idea that every man should be his own landlord has been fostered by building societies and other organisations more or less interested. It is not denied that, when first built, houses of this kind were sanitarily built and tolerably perfect in construction. They have all modern appliances of the time. But have they remained in this state? From investigation of such property at Leith and other towns, it is found that a large proportion of these houses are in a bad state of repair and unfit for habitation. The result is attributed to several causes, and amongst them we may name the following. First, every house is subject to decay, and requires a constant outlay to keep it in repair and efficiency, and the working class who own their houses as an investment are not in a position to keep up the yearly demands for repair or improvement. The owner, in many cases, has invested all his savings in his house for himself and family, and he does not look beyond his own immediate wants. In most cases, he has made no provision for repairs and other expenses necessary to keep the property up to the time. We often see an instance of this in dwellings which come within the jurisdiction of sanitary authorities. The owner is compelled to remove all the old drains and fittings, and substitute those of approved construction and form. The old fittings have become obsolete. The modern tenant requires the latest improvements and appliances in the shape of ventilators, hot-water or bath apparatus, or lavatory fittings. The mortgaged house is still less likely to get attention to its structural wants. The owner in this case has more than he can do to keep the property wind and weather tight, without spending anything on improvements. It is pointed out also that "the better class of tenants gradually remove to houses of more recent construction, where they find the more modern appliances and conveniences." The consequences are that the houses are let to undesirable tenants, and gradually the house gets into disrepair, and goes from bad to worse.

Again, individual owners of the class referred to rarely set aside a reserve fund for repairs or improvements, and in this particular they manage their affairs very differently to any trading or mercantile business, which sets apart a portion of the profits for this purpose. Mr. Stevenson says, truly enough, herein "lies a pertinent cause of uninhabitable dwellings." In the lower classes of dwellings in large cities the carelessness and destructive habits of tenants contribute to the same result. These are mainly the causes which have to be dealt with before dwellings in our towns can be made habitable or healthy. What is the remedy proposed? Mr. Stevenson says "All individual and private ownership in house property in towns should cease"; he would also exclude the State and municipal bodies, and recommends that the owning of house property be taken up by joint-stock companies or by some syndicate which might be limited and co-operative, in which working men of all classes might join and invest their savings. Such a co-operation would have no risk, as the property would be managed on business principles; the dividends would be paid half-yearly, uniformly, and a reserve for all emergencies and improvements be provided. The company would, for its own interests, keep the houses in good repair, and introduce the most modern and approved sanitary appliances, so as to secure the best class of tenants. Shareholders and members could "bequeath the life rent to one person, and the fee on reversion to others, knowing that the life-renter would have no control in deteriorating the principal, and that the fee would go down to the reversionaries unimpaired." As an example of this kind of association, the author points to the Glasgow Workmen's Dwellings Co., Limited.

The scheme is one worthy of consideration, and we allude to it because it points out some of the undeniable factors in the creation of undesirable and uninhabitable houses in our great towns. The ordinary house owner of the small dwelling buys his property under the impression that it is an investment not liable to decay or deterioration, and that a house once built cannot be improved. Under this impression, the idea of a reserve fund is never entertained for a moment. Herein is one fertile source of all the mischief and the serious insanitary condition of the dwellings of our great cities.

◆

FASHIONABLE BUILDING OR ARCHITECTURE?

To what extent genuine artistic feeling or mere spurious sentiment enters into our modern design, we have little direct means of judging in an age when so many conflicting and varied motives find a place and an opportunity. We can only test these motives by their results, or in how far they subserve the requirements of the day. In the designs for modern buildings, two distinct schools are apparently striving for mastery. We have on one side a considerable number of competent men whose ideas of architecture are very little removed from mere construction, and who cannot distinguish building which is architecture from building which is merely the fortuitous combination of trades. On the other side, we have men who regard architecture as building, and something more, who with taste and discretion seek to impart to mere building a sense of artistic fitness and poetry. The man who looks upon architecture as nothing but "decorated building"—and there are hundreds of such men—is one who believes in iron girders when any difficulty arises, likes to hide his roofs, colour and tuck-point his front, and do many other things which are simply atrocious to a man of taste. Our average commercial buildings and shops are examples of the decorated building ideal; but it extends to other buildings as well, our town halls, vestry offices, and public libraries. And is not the labour also misdirected? The architect who takes a low building view of his art is generally fond of cheap ornament and decoration; it hides his want of invention and artistic weakness, for in this matter, as in other things, "extremes meet." The plain unsophisticated, common-sense builder often does something infinitely more artistic because honest, than he who smothers up his unthoughtful work with make-believes and shams. Many a factory or an engine-house is more architectural than a commercial architect's best work. Our simplest and plainest buildings which have been honestly planned to meet what is wanted, as the old-fashioned cottages, barns, and homesteads, or the unpretending village churches that we meet with in Somersetshire and Sussex, often give us hints, and our leading architects still take them as models. Then we have the second class, who from natural instinct and education cannot do many things which seem reasonable in the eyes of the mere "architecturalist," if we may coin a word to designate the men we have just spoken of. Certain things would be impossible or utterly repugnant to the artist, as, for instance, making it appear that a front rested on an entablature or over a plate-glass window; designing an elaborate façade to the street with plain return sides; sham gable fronts, repeating features for the sake of symmetry, putting iron pillars under flat ceilings, iron spiral staircases, ornamental leaded lights, and other shop-fitter's decoration. For the professional decorator's art he has a particular distaste; decoration is to him a very different thing, it means treatment of materials, variety of form, vigour of line. For example, to take a common case, decorating a panel is not the same thing to each of these classes. To one it means *covering* it with decoration; to the other it means leaving portions of the ground untouched. Wall decoration, to the ordinary decorator, is crowding the surface with an elaborate pattern; to the true artist it is treating the surface in such a manner that the eye can appreciate the value of the scheme as a whole, the plain surfaces, the relation of curved lines to straight, difference of texture, light, and shade. Again, let us take another very favourite object for decoration—the column. The common idea is to put some ornament round the column—raised ornament, spiral mouldings, or what not—for the purpose, if anything, of concealing or counterfeiting the column; the true decorative spirit suggests the emphasis of the column as a *support*, to preserve its real outline, so as to give an expression of strength. The ornament he uses is appropriate also in line and in low relief, and rigid rather than weak and naturalistic.

In the more constructional arts of brick and stonework the same divergence of thought and feeling appears. The average designer likes plenty of carved work and panelling; the more of it the better, and the craftsman entertains the same regard for work which is full of labour. He prefers a moulded or carved brick or stone arch to a plain one over a door or window; he would not put a plain stone lintel over an opening if he could use a pediment. For a large blank surface of wall, with two or three windows in it, arranged apparently at random, he has no admiration; nor can he understand the value of a plain and lofty chimney-stack. But these are features which the artist holds in reverence as honest expressions of building. Then as to the kind of relief given to brickwork. The most rational appears to be the vertical membering seen in North German work, as in gables, which gives real as well as decorative value to walls and stacks. These structural lines are not those which find most favour with architects of the "decorated" building kind. They prefer heavy and elaborate cornices, which are top-heavy and unstable; or panelled and carved surfaces. Much of their want of discernment of what is proper is due to their absence of knowledge of the traditional mode of workmanship in brick and stone which has been inherited through many generations. The old artist and craftsman naturally succeeded to this endowment of method and traditional skill; but the modern art designer has no part or lot in it; it is quite as foreign to him as the costumes of the Plantagenets or the Tudors. Only those who have patiently studied the old work and imbibed the true spirit of its workers can understand or appreciate those ways of doing things which have ever seemed the truest and the best. Mind, we do not say followed the letter or revived the dead forms of past art, but have caught the true *method* of the old work. We may observe the same difference of design in woodwork. The Gothic woodwork was simple and solid, and even the later Renaissance, from which our modern furniture and decorative woodwork are copied, showed a national character; the framing was honest and solid, the mouldings delicately wrought, and there was breadth and sobriety in the design. The craftsman was a master of his trade, he was a member of a guild which became the depository of traditional skill. He had an intuitive idea of what be wanted, he used his material with meaning, and worked with reserve and thoroughness. His modern successor of the showy school can claim none of those qualities.

Modern domestic interiors afford us a capital idea of the divergent views of the decorative builder and the true architect. On one side we see commonplace and vulgarity; on the other, simplicity, solidity, and quaintness. In the first case the plainest and commonest building as regards plan and design is made the groundwork for a variety of fancy designs. The bare walls are covered with "art" papers or applied decorative materials, the floor is parqueted, and the ceiling divided into panels. The "decorative" architect goes in for all the latest "crazes" in woodwork and wall linings. These are to his hand, and he has only to apply them. He does not think it necessary to change the shape of his rooms, to make his walls thicker, to build recessed jambs, if he can obtain all the effect in a cheaper and more expeditious form. For example, if he can introduce a panelled fabric for his walls, he sees no need to erect pilasters or to specify solid oak or walnut wainscoting. Modern decorative taste is nowhere more assertive than in that essential provision of the English home—the fireplace. On this feature, the decorative architect of the modern commercial type is wont to lavish all his attention. The ironmonger, the marble mason, or the furniture maker can furnish all he wants to make it "chic," or agreeable to the taste of the day. The illustrated catalogue of a stove manufacturer will give him the latest pattern in which fashion and quaintness are blended. As for the mantelpiece, this same order of interior has a stock design in walnut or cast iron as appropriate as it is obtrusive. Atrocious colonnettes, figures, and mouldings, abound, quite out of keeping with the meagre look of other details of the room. If of marble, or an artificial material, the design is often more repugnant to good taste. In these fittings we have a notable instance of misapplied craft, or sometimes excellent workmanship devoted to atrocious design. The architect who employs this sort of art is wise in his generation, for he gauges accurately the taste of the public, which prefers a blend of the showy and sentimental. If we turn to wall decoration, we see that the low-priced, showy wall-papers, or the inferior imitations of the better designs, have by far the best chance. Fashion and archæology is a mixture which the modern architect of the class we are describing strongly affects. On the contrary, the honest designer takes a commonsense view, and adapts his design, whether it be a chimneypiece or decoration, to the purpose it is intended to fulfil. He sees no good in giving a new dress to anything, if an old form is better suited to it. Fashion or novelty he despises for its own sake, and this is one reason why a few among the profession who have been foremost in their revival of "Queen Anne" or English Renaissance are condemned for their use of old and quaint methods. They are charged with having no sympathy with the age, with giving us antiquated houses and furniture and old-fashioned wall-papers, with a kind of affectation for everything which savours of the last century or two. Is it not rather that they are disgusted with modern shams and trickery, and are anxious of bringing back the honest design and workmanship of the best periods; because they find that the old methods give the most comfort; that the quaint wide fireplace and "ingle"-nooks are better ways of utilising heat and economising space? The reserve and quietness in the work of this school of thought cannot be put down only to affectation of quaintness; they are qualities that find a response amongst people who dislike ostentation or a parade of mere fashion; who admire art of this kind for its honesty of purpose, and for the refining grace which the artist has been able to bestow upon every detail of his work. The fashionable and commercial designer is never particular as to details; it does not pay him to trouble much about them, for he finds his customers content with general effect.

"OLD MASTERS" ON THE CONTINENT.—XX.

By Charles L. Eastlake

(Keeper of the National Gallery).

If the primitive but useful custom which so much prevailed in portraiture during the 15th and 16th centuries had been universally adopted—viz., that of inscribing on a corner of the background the name of the person represented, posterity would have been relieved from a vast deal of trouble, and the history of pictorial art might have been enriched by many details which at present remain obscure. There is scarcely a gallery in Europe which does not contain some important work overshadowed by doubts even as to the identity of the painter, because the features which he transferred to canvas have remained unrecognised. The so-called "Fornarina" in the Uffizi at Florence is a case in point. The interesting "Portrait of a Young Man," ascribed to Francia Bigio, in the Louvre, is another instance. The old Pinakothek at Munich contains the likeness of a merchant once believed to have been painted by Garofalo, but the merchant's name and the authorship of the work are both involved in obscurity. In our own National Gallery the admirable portrait of Cornelius van der Geest—one of the chief gems of the collection—was long supposed to represent Caspar Gevaerts (Gevartius), the friend of Rubens, and though the picture is catalogued, with excellent reason, as an example of Van Dyck, some adventurous critics still maintain that it is the work of his distinguished master.

That a picture by Holbein could ever have been attributed to Leonardo da Vinci seems incredible in these days of enlightened connoisseurship. Yet this egregious blunder was perpetrated, and prevailed for nearly a century regarding the famous portrait of Morette which hangs in the Royal Gallery at Dresden. The mistake is all the less excusable because the *provenance* of the picture was well known. About two hundred and fifty years ago it belonged to the Marchese Maximilian Montecuccoli, then enyoy at Parma and Rome; from whose possession it passed into that of Duke Franz I. at Modena, and at that time it was known as the work of Holbein. In 1746 it was removed from Modena to Dresden, when it seems to have passed for a portrait of Ludovico Sforza by L. da Vinci. In 1846 Rumohr, who succeeded in exploding this theory, expressed his belief that it was from Holbein's brush. But a further mystery remained respecting the subject of the picture. Ludovico Sforza had been known as "Il Moro," a fact which in itself should have dispelled the idea that it was his portrait, seeing that the complexion of the sitter is not dark, but ruddy. Possibly this *agnomen* may have led to further speculation. At any rate, Herr von Quandt published an article in the *Kunstblatt* of that day to prove that it was the portrait of no Moor, but of "M. Morett," a jeweller employed by Henry VIII. This explanation was gradually accepted, and seemed so satisfactory that for many years the picture was officially catalogued under that title. In due time, however, further researches were made, and a new light seemed to be thrown on the subject by the discovery of a letter from Sir Isaac Wake to William Boswell in the 17th century. The following is an extract:—

"Turin, $\frac{\text{November 26,}}{\text{December 6,}}$ 1628.

"My dear Friend and Sweetheart,

* * * * *

"The picture after which you do seem to inquire was made by Hans Holbein in the time of Henry VIII., and is of a *Count of Moretta*. My Lord of Arundel doth desire it, and if I can get it at any reasonable rate he must and shall have it. * * * *

"Your faithful friend and servant,
"I. Wake."

The supposition that the picture was intended for Hubert Morett, the king's jeweller, had been to some extent based on an inscription which appears on Wenzel Hollar's engraving of the portrait. But it so happens that while Holbein was employed by Henry VIII. there was about the Court a certain French nobleman, the Sieur de Morette, and if we have to choose between these two personages, it seems far more probable that the painter received his commission from a foreigner of distinction than from an English tradesman. Such, at least, is the conclusion at which most modern critics have arrived, and it is evident, from the description of the picture which appears in the official Catalogue, that Prof. Woermann, Director of the Dresden Gallery, inclines to the same opinion.

The portrait which has been selected for illustration with this article is of life size, and rather more than half length. It represents a bearded man, above fifty years of age, whose sandy-coloured hair is beginning to turn grey. His fine, square head denotes power and intellect, and the admirably-modelled features are inserted with great vitality, but the expression is peevish and almost forbidding. It is the face of a person with whom it would be dangerous to quarrel. He is dressed in a black satin doublet with slashed sleeves, disclosing the ruffles of a cambric shirt below. He holds a glove in his right hand, while his left rests on a sheathed dagger which hangs from his waist. Over the doublet he wears a black silk cloak lined with fur. Round his neck is a gold chain with a locket attached to it. His flat black cap is stitched with gold thread and enriched by a cameo brooch or medallion. In the background is a green curtain of figured silk.

It would be difficult to overrate the quality of this excellent and characteristic work. As a portrait it is full of interest, while the technical skill with which the texture of fur, silk, and other details of the dress are rendered, shows the hand of the master throughout. It is painted on panel about 3ft. high by 2ft. 6in. wide.

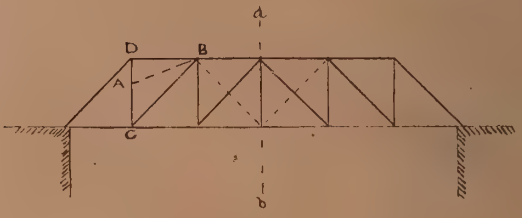

Fig. 4.

DESIGNING OF STEEL BRIDGES, THEORETICAL AND PRACTICAL.—XXI.

We have now to consider a little more fully the examples of open-web girders and trusses, to which the general equation already given—

$$S = (2 \times A - 3),$$

is particularly applicable. The duty of redundant members or counterbraces, as they are termed, to distinguish them from the principal or main braces of a truss, and the conditions governing their use, have also to be investigated, and the proper rules regulating their employment deduced and applied. A simple example of an open-web girder is shown in Fig. 1, which is supposed to be uniformly loaded on the bottom flange A F. It should be mentioned here that although the terms are not always strictly synonymous, yet "flange," "boom," and "chord" are frequently used in the same sense. The last word is very commonly employed by American engineers, and no doubt took its origin from the circumstance that timber bridges were so largely built in that country. As generally understood in England, the term "flange" is scarcely applicable to bridges built of timber, into the construction of which angle, tee, channel, or other sections of steel do not enter as part or parcel of either the upper of lower chord. The word "boom" was originally intended to signify, after a nautical fashion, that it was the longitudinal member of the truss that stretched or kept taut the sides or web as they are styled, in the same manner as a boom or yard keeps a sail stretched. Whether the boom stretches the web, or the web keeps the boom taut, is a doubtful matter in actual practice, especially when the element of deflection, which is merely a small amount of deformation, is in a vertical plane, and in a state ofs table equilibrium. It has been stated by some authors that the sides or web of open-web girders and trusses have no influence on the amount of deflection under a heavy passing load. When the depth of the girder is comparatively small in its ratio to the span, this statement may be approximately correct; but in large and deep girders of long span, it is by no means a true one. In all such structures, the depth very considerably modifies the deflection.

Since the load on the girder, shown in Fig. 1, is supposed to be uniformly distributed over the lower chord, it may be regarded for the purpose of calculating the resultant stresses on the different members of the truss, as if equally apportioned upon each of the lower apices, K H G. The manner in which this description of loading will affect the individual and separate parts of the truss is shown in Fig. 1, in which the character of the various stresses are represented by thick black lines for those in compression, and by similarly thin lines when they are in tension. If, now, we apply our general formula to the truss in Fig. 1, we shall find S to be equal to 15 and A equal to 9, and the equation will furnish the identity—

$$15 = (2 \times 9 - 3) = 15.$$

If we now introduce two other bars, A C and D F, the equation becomes, substituting the proper values for S and A respectively—

$$17 = (2 \times 9 - 3) = 15.$$

In other words, both bars are redundant under—and this is an important reservation—the supposed uniform distribution of the load. What has been actually accomplished by the introduction of the two new bars or members requires a like attention. A reference to Fig. 1 will point out that, while two additional bars have been inserted in the truss, no additional apices or angular points have been introduced. Consequently in the equation—

$$S = (2 \times A - 3),$$

the quantity on the left-hand side of the equation has changed in value, while that on the right has remained constant. It may, therefore, after this explanation, be inferred in future, *à priori*, that additional members or bars, introduced into a truss without increasing the original number of apices or angular points, will be redundant, unless the truss should be deformable, and not, therefore, fulfilling the required conditions expressed in the general equation.

If the truss in Fig. 1 be loaded on the upper chord, and supported, as it sometimes is in construction, upon a hinge or shoe attached to its upper chord, as represented in Fig. 2, the bars A B, A K, and E F, F G, shown in the truss in Fig. 1, must be omitted, and it remains to be seen whether the truss, when shorn of these members, will fulfil the conditions of indeformability. In this case the value of $S = 11$, and $A = 7$, and we obtain—

$$11 = (2 \times 7 - 3) = 11.$$

From what has been previously stated, it is known that, in a theoretical point of view, the two bars C G and D K, shown by the dotted lines in Fig. 2, are redundant. Nevertheless, it might, under certain circumstances and conditions of loading, be practically very advisable to add them for the purpose of stiffening the truss. Under a uniform load on the upper flange, there will not be any resultant stress upon the central bars C H and D H, in Fig. 2. Another example of a truss is shown in Fig. 3, in which, with a load uniformly distributed over the upper boom, the vertical members will be in compression, and the diagonals in tension, as shown by the thick and thin lines. In this instance the theoretically redundant member or conterbraces, represented by the dotted lines in the figure, are absolutely essential in every similar girder and truss subjected to a moving load. Applying the equation, and neglecting the counterbraces, we have, with the proper values of S and A—

$$25 = (2 \times 14 - 3) = 25.$$

It is unnecessary to repeat the calculation to point out the theoretical redundancy of the counterbraces under the assumption of a uniform distributed load. From the example of girder in Fig. 3 may be derived the general rule that where vertical members in the web of an open-web girder are employed, and two sets or systems of diagonal bars intersecting one another, and introduced, there is a corresponding waste of material. The railway bridge over the Thames at Charing Cross has been frequently quoted as a case in point. In each main girder there are some thirteen or fourteen tons of useless and extra material in the form of double vertical bars at the apex of each panel length in both the upper and lower booms. Sufficient practical examples have now been adduced to distinctly indicate and explain the relations existing between their various arrangements of parts and the rule governing their liability to deformation or even torsion. There are altogether three general equations applicable to this subject, one of which has already been enunciated, and using the same notation for the number of parts and angular points or apices in the truss is—

$$S = (2 \times A - 3) \ldots\ldots\ldots\ldots\ldots (1)$$

Any girder or truss which under a uniformly distributed load satisfies this equation of whatever shaped figure it may consist, is not only indeformable, but has, in addition, no redundant members. It possesses, in fact, the smallest number of parts necessary to impart indeformability to it under the conditions assumed, commencing with the simplest form, that of the triangle, to the most complicated polygon that can be delineated. When the truss happens to be endowed with redundant members, the formula becomes—

$$S > (2 \times A - 3) \ldots\ldots\ldots\ldots (2)$$

showing that the numbers of the different members are in excess of those actually required. It follows as a corollary from equation (2) that a redundant figure must necessarily be also indeformable. The third formula is just the reverse of the former, for it applies to girders and trusses which are deformable—that is, which do not possess a sufficient number of individual parts. For these trusses the equation becomes—

$$S < (2 \times A - 3) \ldots\ldots\ldots\ldots (3)$$

If the load on the girder in Fig. 3 be supposed to be situated uniformly along the lower chord, the bars A B, B H and D E, D G may be omitted, and the truss will take the form given to it in Fig. 4, in which the arrangement of the bracing is altered, the vertical members being now under tension, and the diagonals in compression. Although there is considerable latitude allowed to the designer with regard to the particular system of bracing and arrangement of bars he may choose to select, yet there are at the same time many well-recognised forms of open-web trusses from which it is not generally advisable to depart, except for especial reasons dictated by the particular character of the case, or where girders of a very large span are called in question. No doubt the larger the example of construction is, the more scope there is for a display of the inventive faculties, skill, experience, and ability of the professional man. Also, it must be remembered that, on the other hand, the very same circumstances not only call for, but demand, a very high standard of education, training, and knowledge on the part of the engineer, architect, and builder.

Giving to S and A their proper values for the truss in Fig. 4 of 21 and 12 respectively, we obtain the identity—

$$21 = (2 \times 12 - 3) = 21$$

It will be observed, on referring to Fig. 4, that the two redundant members or counterbraces shown by the dotted lines are inclined in exactly the contrary direction to that which they occupied in Fig. 3, and they are also subjected to stresses of opposite character under the same conditions of a rolling load. Before leaving this part of our subject, the practice of "cutting-down," so to speak, the trusses in Fig. 183 to the forms in Figs. 2 and 4 by pruning off the several parts previously enumerated, is not to be recommended, except for bridges of small spans under 80ft. for railway bridges, and 100ft. for road bridges. We are not, and never have been, advocates for cutting down and skimping useful material, except when it is in the wrong place. In the small examples of bridge girders, in which the individual parts are comparatively slight, and of small sectional area in themselves, it is very false economy to impair the stability and rigidity of the structure, regarded in its entirety, by snipping off a bar here and there, simply on the plea that it could, theoretically, be dispensed with. The actual saving of material is not worth considering; and besides, if the principle be indulged in to any great extent, it invariably leads to a cramped and defective style of designing which finds little favour in the eyes of thoroughly sound and experienced arbitrators and judges. The case is far otherwise when girders of considerable magnitude are in question. Each separate member becomes then a small built-up girder in itself, and its own sectional area and weight are more than sufficient to bestow upon it that condition of rigidity and stable equilibrium which the smaller specimens do not possess.

Redundant members may evidently be divided into two principal classes:—

(1) Those which are theoretically redundant, and not necessary for the indeformability of truss, but which are indispensable for practical reasons, and they then become counterbraces, and must be designed and treated as such.

(2) Those which are redundant both theoretically and practically. An instance of this duplicate redundancy is shown in the truss in Fig. 4, by adding the bar represented by the dotted line A B. Although it adds one more side or separate part to the whole truss, it does not alter the original number of the apices or angular points, and will, therefore, not satisfy equation (1), and is theoretically redundant. It is equally so practically, for it is impossible to ascertain exactly what portion of the stress at the apex B might be taken by it, and what by the proper brace B C, both of which would be in compression. The principal mischief which it effects, which would alone forbid its use—even if it had any—is that it brings a cross stress on the vertical brace C D. This last member is a tie, and not intended to resist the thrust which the bar A B would bring upon it, and if, perhaps, in solid beams and girders, a few unregarded or imperfectly ascertained stresses may adjust their differences among themselves—as it were, become absorbed in the whole mass—such an adjustment does not present itself in open-web girders and trusses. The lines of action or direction, of all the weights, forces direct and indirect, and the resulting stresses brought upon any one member by the stresses upon any of its fellows, are too unequivocally marked out in intensity, character, and position, to allow of any appreciable deviation from the path prescribed by theory and assigned by practice. The manner in which counterbraces act under a moving load, and the necessity for them, will be fully explained by a practical example in our next article. It is important to bear in mind that both the main and the counterbrace cannot be in action at one and the same time.

COUNTY LUNATIC ASYLUMS.—XXVI.

By George H. Bibby, F.R.I.B.A.

WORKROOMS FOR FEMALE PATIENTS.

THE occupation of female patients, beyond what work can be given them in the laundry, the kitchens, the wards and dormitories, and in the sewing and knitting-rooms, is occasionally a matter of considerable difficulty. It is obvious that many of the patients may be, for a variety of reasons, absolutely unfitted mentally, physically, or as a result of their previous training or condition of life, for any of the above named employments.

Having in view the very high importance to the patients that they should not be permitted to pass away time in idleness without a great effort upon the part of the officials to provide them with suitable and interesting work so soon as they may be found capable of employment, it appears to be necessary that the architect should provide in his plans of the wings of the buildings for female patients something more than the rooms for needlework, &c.

Long galleries or workrooms, divided at intervals (generally with glazed screens for purposes of observation), are as necessary as in the buildings for the male working patients, the worktables and seats being placed so that the women may have a cheerful look-out (the window-sills to be not more than 3ft. in height above the floor), and, as on the men's side of the building, in lines parallel to the length of the apartments, which should be so constructed that patients may not necessarily have to pass through divisions occupied by other classes of workers to reach their own wards or the lavatories and waterclosets.

There are more than 120 trades or occupations at which the female patients of the London County asylums have worked prior to their admission, and at several of these it is probable that patients could work or be taught to work, provided that suitable buildings be erected.

Amongst these are (in addition to the knitting, needlework, and laundry workrooms) apartments for basket-making, the manufacture of cardboard boxes, straw-bonnet makers, artificial florists, cigar and cigarette-making, folding and stitching books and pamphlets and reports, tailoring, millinery work, weaving, bookbinding, French polishing, and many others, and the larger the asylum the greater would be the opportunities of variety in the occupations and number of workrooms.

All these trades are suitable for the more intelligent classes of patients, and when the numbers to be employed upon some of these may be but few, one or more trades might be in some cases conveniently followed in the same apartment, provided that the patients thus associated can be in other respects suitably associated as regards their temper, bodily or mental health. Very large numbers of females are employed in London cigar manufactories. The work is of a simple description, and each worker usually has an allotted space of about 2ft. 6in. by 2ft. 6in. at a long table, divided from her neighbours by divisions about 6in. in height, so that each worker may be able to keep separate her supply of raw and manufactured material. There are some thousands of these cigar-makers in London alone, and the nature of the work is such that they are able to do what is required in a very small space, and, in consequence, are, in private factories, occasionally unduly crowded together without sufficient cubical contents in the rooms, or without adequate means of escape in the event of fire or panic.

In the room for cardboard and fancy-box-making glue and paste would be considerably in use; therefore a steam apparatus for boiling these would be advisable, and as the materials for making boxes are inflammable, an open fire or gas apparatus would be objectionable for obvious reasons. Similar precautions must be observed in the book-folding, artificial-flower making, and other rooms.

For female patients of a very low state of intelligence the picking of horsehair is a very suitable occupation. This work is constantly needed in asylums, and is not difficult to execute. The hair should always be thoroughly cleaned, and, if possible, steamed, before it is given to the patients to be operated upon. This work should be done in a separate and well-ventilated apartment, and certainly never in the wards. The picking should be done first by the less intelligent patients, and completed by a better class in another room.

In several architectural competitions in connection with asylums proposed to be erected with a view to future extension, it has been usual to demand that the administrative portions should be sufficient for the ultimate capacity of the institution. This requirement, however, need scarcely apply to the workshops, as temporary divisions of the various apartments might be made.

If from circumstances the workrooms must be situated at a distance from the wards, it would be well to provide a room (about 14ft. by 7ft.) in connection with the workroom blocks, to which those patients taken with epileptic fits could be removed without having to be conveyed to a considerable distance. This room would correspond in all respects with those frequently placed near the entrance to the asylum chapels, and previously described, and a convenient place should be provided for a movable couch about 5ft. 9in. long by 2ft. 3in. wide and 18in. in height. It should be provided with rubber-covered wheels about 8in. or 9in. in diameter, and would be required for the immediate removal of patients taken ill or suffering from fits during the working hours.

Whatever may be the financial profits from the work of asylum patients as a whole, there can be no doubt that the returns resulting from the labour of individual patients are in many cases very highly remunerative, and that the so-called pauper-patient not infrequently does more than earn the cost of his maintenance in the asylum (in which he may be confined for no reasons affecting his ability to work at his trade, in which he may, indeed, be a highly-skilled workman). Therefore, in the construction of the work buildings, every reasonable convenience should, if possible, be provided, that all who can be induced to work may do so under the most favourable circumstances procurable.

Epileptic patients, for instance, are usually considered to be very good workers, being very frequently strong and energetic; but they are so liable to sudden falls, that they should not be permitted to work near to open fires, high places, or under other similar dangerous conditions, and, where practicable, all sharp corners and necessary projections should be rounded off in the workrooms and approaches thereto, and it should be noted that all severe injuries to the head are known to be of great importance in the production of insanity—whether these consist of fracture of the skull, extravasation of blood, loss of cerebral substance, or simple concussion; and while in the most severe of these cases the resulting mental disturbance generally appears at once or on recovery from the actual injury, in other cases it does not appear till much later, perhaps not until even ten years after the accident; and in certain instances concussion may be followed by such results within the brain that it remains for years very susceptible to disease, so that after the slightest exciting cause insanity is produced.

The workrooms both for male and female patients should, if practicable, be always in one-story buildings; but whenever, for economical or other sufficient reasons, two-story buildings must be adopted, the staircases should be in short, easy, straight flights, and be constructed with fire-resisting material, inclosed within brick walls; or if, by reason of the varying levels of the site or kindred causes, it be found convenient to form an inclined plane to the upper floor, the higher portions must be protected with railings, with the view of preventing any of the patients from throwing themselves over to the ground below, or from placing themselves in danger by climbing to positions from which they might fall.

There would be less objection to a two story building for workshops if the lower floor were sunk below the ground level to a depth of 3ft. or 4ft. By this means a much more economical arrangement would be obtained, and considerably greater accommodation obtained at a lower cost, as *practically* the same foundations and roof would serve for a two-story as for a one-story erection. The ground level being midway between the floors, it would be much easier to arrange for inclined planes to both floors, or, in the event of staircases being necessary, the height of the same and number of steps would be greatly diminished, a manifest advantage to the working patients (especially when carrying loads of materials and goods); but the window-sills of the lower floor being thus placed on a level with the ground, special care would be observed to provide against breakages of glass.

These apartments could scarcely be termed "underground workshops," inasmuch as the whole of the window area for lighting would be clear of the general ground level. There should, if possible, be an outside area extending to the level of the lower floor. This, however, *must* be covered with iron bars to keep the patients from falling through. There should be a floor of wood in all the rooms (unless the nature of the work specially disallows this), and the whole should have a bed of concrete beneath all usual and necessary structural precautions being observed to keep the apartments dry.

The danger to the mental and bodily health of working asylum patients by putting them to unsuitable employment cannot be disregarded, and it has been frequently observed that thwarted plans and determinations (for example, an occupation enforced while all the inclinations of the individual are directed towards engagements of quite a different nature) become the causes of an intensified insanity. It would, therefore, appear to be somewhat difficult to know how to employ those patients, during rainy and winter seasons, who usually work in the gardens, or upon fields and roads attached to the asylum. Amusements are, of course, not always practicable at these periods, and idleness cannot but prove to be a calamity to be avoided by sane and insane; therefore, some workroom accommodation should be provided beyond what is requisite for those whose work is chiefly indoors, so that the workrooms be not overcrowded during unseasonable weather, and this precaution should be especially observed in those asylums where the inmates are largely drawn from the agricultural districts, and where the farmlands attached to the asylum are of an extensive description. To billet these occasional indoor workers amongst those who are continually within the workrooms would be manifestly disadvantageous to the discipline of the asylum, for in every well-ordered institution there should be a proper separation of the inmates, so that each patient shall, so far as is practicable, associate only with a few whose company is suitable; and a new patient should, for example, never have any intercourse with the bad and hopeless cases. Such an arrangement could not fail to have a very deleterious influence upon him. An eminent medical authority upon asylums has written:—"Those patients who come into contact with one another, though on the best of terms, are, at the same time, profoundly indifferent about each other, each one being almost wholly occupied with himself. Many remark the insanity of others, and become cognisant of their own state by observing that a similar treatment is adopted towards them; and it exerts the most beneficial influence upon the new patients to be led spontaneously, through the example of those around them, to conform to the order and routine of the establishment, and to learn from the others submission to all over them, and from the recoveries and dismissals taking place around them, to become tranquil, and encourage the hope that they too will some day be dismissed."

In the separation of patients according to their supposed condition or outward demeanour, caution has to be observed not to carry it to such an extent in the planning of the workrooms as to subdivide the service too much, and thereby unreasonably augment the requisite amount of superintendence.

In former times little or no provision was made in asylums for the employment of the insane, and attempts to amuse or instruct them were very deficient. Probably workrooms were wholly unknown. The progress in this direction has been but slow, until about twenty-five years ago, since which time it would appear that architects and medical superintendents have, by their joint efforts, greatly improved the general arrangements of asylums in many respects, while the modern inventions of the telephone, electric lighting, and improvements in cooking, laundry, ventilating, heating, and engineering have all contributed to make some modern asylums marvels of constructive ability upon the part of those who have produced them. As now planned, they are vastly superior to those existing in 1845; but even then, in different countries where the subject of insanity had commenced to receive serious attention, widely different architectural arrangements existed A writer in that year stated that "while the English institutions in general present a most imposing appearance by their massive and elegant exterior, possess the greatest completeness in the interior as regards convenience of space and all domestic arrangements (as heating, lighting, cleaning, working arrangements, &c.), and, combined with great comfort, a certain regularity of routine that corresponds well with the almost mechanical nature of the superintendence and treatment, the French asylums, on the other hand, are (1845) constructed on quite a different principle, especially those formed on Esquirol's plans. They consist of a series of square houses, widely apart, of merely a ground-floor containing a number of single cells or rooms, a common conversation-room, work-room, &c., with a colonnade around, and inclosing in the centre a plot of grass. Several parallel rows of such single-storied squares are connected together by those colonnades, including the store-houses, work-room, chapel, bathing-houses, &c. This mass of distinct buildings, which occupies an immense area, is not only more costly to erect, but renders the oversight more difficult, and affords fewer facilities of visiting the more distant parts of the institution and of general superintendence. On this account, up to the period when, by the *introduction* of *labour and instruction*, quite different principles were followed in the construction and arrangement of French asylums; these institutions were distinguished by a want of restraint, the uncontrolled roaming about, and unruly character of the patients. In the construction of the most modern institutions in France, the ideas of Esquirol seem to have been considerably deviated from. In Germany there has been an attempt to combine the good qualities of both systems, although upon the whole the German institutions approach nearer in their construction to the English asylums than to those formed on the plans of Esquirol. The newer institutions are usually so arranged that in one, or several, central buildings of two or three stories in height, the common rooms, the office, the chapel, the kitchen, the washing-houses, the store-rooms, the rooms of the officials, are all together. From each side of these one or two double-storied side-wings extend, either in direct communication or detached. In these are the different divisions for convalescents, boarders, quiet patients of middle and lower rank in life, together with attendants' accommodation, baths, &c. As a completion to the whole are small single-storied buildings as far as possible removed from the centre, which contain the cells for unruly patients, especially those requiring isolation. Each division of the house must have its own garden and pleasure-grounds for its inmates; all the stairs, windows, and doors must be seen to, that they are not only of sufficient strength, but also that they are of the simplest possible mechanism, and a sufficient guarantee for the security of the patients. The internal fittings of the dwelling and sleeping apartments in the division for the noisy and maniacal must be of the simplest description. They must also be immovable, and in the other parts of the institution simpler or more elegant, according to the station and requirements of the patients."

The foregoing gives what appears to be a fair description of asylum arrangements in England, France, and Germany some fifty years ago. Even then some attention had been directed to the necessity for providing workshops for the employment and instruction of the patients; but their occupation in asylums is still a matter of considerable anxiety to the various authorities, and of continual investigation, I believe, by the Commissioners in Lunacy, whose reports as to England and Wales concur with those of the authorities in Scotland and Ireland as to the insufficiency of the existing means of suitable employment of patients in asylums.

(*To be continued.*)

THE CANARY ISLES: STRAY NOTES DURING A RECENT VISIT.—II.

CLOSE to the English church outside Las Palmas is a particularly good wooden detached villa, roofed in with stained shingles. We pronounced it American at first glance, and so it proved to be. Its story is somewhat curious. It was originally shipped from the United States to England, the steamer calling on its way across the Atlantic at Las Palmas. In London it was bought by a gentleman, who brought it over to the Grand Canary again, and caused it to be erected where it now stands, an ornament and a pleasure to all who see it. The architecture of the United States generally does not find favour with the average educated eye; but in the designing and erection of villa residences American architects quite "take the cake." Nothing better, architecturally speaking, to our mind can be seen on the outskirts of any English or Continental city than the houses found in the suburbs of many American cities. Even Chicago, awful and intensely coarse as it is generally, can fairly and honestly boast of hundreds of capitally-conceived outside-town residences.

At Las Palmas the roofs are generally flat. During our stay at this city we were fortunate in having as fellow guests at our hotel (Hotel Metropole) Mr. Alfred Bovill, F.R.I.B A., architect, late of Buckingham-street, Strand, W.C., and at one time, we believe, the district surveyor of St. Pancras, N.W., and Mrs. Bovill, a most charming lady as well as an accomplished artist. Their present residence is at Villa Orotava, on the Island of Teneriffe. This place was formerly Arautápala, the capital, whereat lived the last Guanche king. Villa Orotava bears the goodly repute of having the finest climate in the whole world. Mr. Bovill, who is an ideal-looking jolly Englishman, had come to Grand Canary anxious to buy a cargo of pitch-pine for one of his clients resident on another of the islands, and to him we were indebted for much practical information upon local building matters generally. The flat roofs, he told us, have splinters put from joist to joist (these joists are commonly of téa, a native pine), and on these three layers of concrete, made of volcanic ashes and lime, 9in. or thereabouts thick, are laid. After this has been well rammed, a top coat of sand and lime is floated, and afterwards rubbed with stone to a smooth sanded face, and washed over with hydraulic lime. Wheelbarrows are unknown. Clay and sand are carried in small baskets. The bricks (5in. by 11in. by 2¾in.) and tiles (the latter are all semi-circular) cost about £2 per 1,000. The tiles go 30 to a square yard. Deals cost from £6 to £8 per 1,000ft. super. by 1in. thick. Pitchpine, which is very largely used, costs £9 for the same quantity. It is chiefly shipped to the islands from Florida in schooners of 300 or 400 tons burden. There appear to be a large number of cabinetmakers on the islands. These almost entirely use pitchpine, and very creditable work they do. Furniture, however, is largely imported. The first bullock-waggon we saw going up the steep roadside at Teneriffe was laden with a big packing-case, with "From Maple and Co., Limited, Tottenham Court-road," in distinct letters on its outside. The original pine on Grand Canary has nearly all been consumed. It is very hard, sinks in water, and a stick of it set alight at one end burns like a candle. Fuerteventura furnishes the best lime. It costs 1s. per 80lb. The stone at Grand Canary seems to be better than that on the other islands. A common stone called *tosca*, a friable material—some of it white, and in other quarries red—is worked into blocks 1ft. 8in. by 11in. by 6in. These are brought into town, tied by ropes, on long narrow waggons, or on the backs of horses, camels, and mules. They cost 2½d. to 4½d. a stone, the price varying with the distance taken. They are generally used for quoins, &c., to houses. In the country places the usual way of building seems to be to collect the boulders and stones, and with them make the outside of a wall 1ft. 8in. or 2ft. thick, and fill up as one builds with puddled local earth, which soon sets almost as hard as mortar.

At the time of our visit (last month) the working hours in the building trade were from 5.30 a.m. to 7 p.m., with two hours out for meals. The toilers practically work from sunrise to dark, so that in the winter the hours are two less per diem. Carpenters, masons, and other trades incidental to building get about 3s. a day in the towns, and 6d. less in the country districts. The average wages of labourers (*Peons*, pronounced *payon*) is 1s. a day; a man and a mule, or a camel, costs from 2s. to 3s. per day. The employer is expected to give the quadruped one feed per diem. In the quarries at Grand Canary, the best of the stonecutters get about 2s. 6d. a day; but many, we understand, only earn 1s. for a like period.

We have already remarked that it is sometimes rather difficult to come away from the Canary Isles. It is also, at times, not so very easy to get there. During our recent visit on the voyage out, we "slowed-down" for many hours, as, it being dark and misty, our captain could not find the bearings of the Isle of Grand Canary. Mr. Bovill records that he once took passage from England to the Canaries, and the weather being bad, the captain refused to land him and eleven other passengers, also bound there, so they were all taken on to Cape Town, the next stopping place—three weeks' passage further on!

The balconies, latticed windows (*postigos*), gurgoyles, and interior *patios*, or courtyards to the houses, and the *miradores*, or "view-towers," are perhaps the most picturesque architectural features in the islands. Many of these are several hundred years old, and evince charming work, both in design and execution. The exterior balconies and latticed windows are often quaintly carved, and nearly always painted. The water-spouts are great features. They project 3ft. or 4ft. out from the flat roofs, and often take the form of cannons, thus making the parapets look like so many lines of fortifications. Some of the designs assumed by these gurgoyles are very odd. Most of the houses are built around a central courtyard, which has a covered way on either side, and flowers, tropical plants, and a fountain in the centre. Herein many a picturesque nook and shady corner delight the artistic eye. The turrets to the dwellings are mostly happy in position and outline. At Las Palmas there is no rain, as a rule, after February until the next year. The beds of the rivers, known as *barrancos*, are everywhere perfectly dry. They are composed of boulders, mostly of volcanic origin, and are often crossed by good bridges. Especially so is the long stone one that spans the barranco near Telde. The main square at Las Palmas—the Alameda—is ornamented by colossal marble busts—one of Columbus, and the other of a native 16th-century poet. In our last we referred to the beautiful specimens of beaten ornamental silver work to be found in some of the churches; that of the Virgin del Pins at Teror may be mentioned as containing a particularly fine shrine of that metal.

Santa Cruz is, of course, the chief port of Teneriffe, although the real capital and seat of the bishopric is La Laguna, five miles or so inland. It was at Santa Cruz that Nelson was defeated by the Spaniards, and lost one arm and two flags. That occurred in A.D. 1797. The flags are preserved in glazed cases, hanging on either side of an altar on the north side of the Church de la Concepcion at Santa Cruz. This church contains a good, if rather high, pulpit of inlaid and coloured marbles, made in A.D. 1736. Its flight of stairs and approach are all in character with the ornate design of the pulpit, and at a little distance look part and parcel of it. As a matter of fact, these adjuncts are nothing but common deal, carefully painted to resemble the marbles used in the pulpit itself. The timbers in some part of the roofs exhibit the ornamental Moorish treatment already mentioned as observed on some of the other islands, and the wrought silver shrines are very beautiful. There are several large new buildings in hand just now at Santa Cruz. One of them, at the corner of a main street, now roofing, is a stone erection of goodly design, and appears intended for bank premises. Santa Cruz, although not such an important coaling station as Las Palmas, does a large and increasing trade in that way. Just outside the town, on the over-Mont-Cenis-like road to La Laguna, is the new bull ring of Salamanca, a large amphitheatre, built seemingly strictly on the lines of Spanish bull rings. It was on this hill, at an outside hostel, known as the Venta de la Cuesta, we tried the weight of one or two of the loads the women carry up the mountains into the interior. It is a usual thing for these hardy creatures to balance 18 large pans of brown clome all tied together upon their heads. Several of these burdens we handled; but each and every one was almost more than we could even lift off the ground. Near here is the oldest church on Teneriffe. It is known as that of Sta. Maria de Gracia. In the open space on which the cathedral at Laguna stands are heavy stone seats of quaint design. The same sort of seats—very effectively conceived—we saw repeated in other parts of the island. Don Alonso Fernandez de Lugo, the Spanish conqueror of Teneriffe, is buried in this cathedral. It also contains a marble pulpit of Genoan make. In the oldest church in the city (the Iglesia de la Concepcion) there is a fine silver reredos. A heavy iron grille at the western end of the church entirely walls it off from the part where the nuns worship. In the Convento de San Francisco is a massive silver altar and a good crucifix. The main road from Laguna to Orotava commences with a long avenue of eucalyptus-trees, in which, at short intervals on both sides of the road, are numerous crosses. Near Tafira, about half-way between Santa Cruz and Orotava, Mr. Comarcho, who owns the popular English hotel bearing his name at Santa Cruz, is building close by the roadside a goodly-sized hotel. It is now being roofed-in, and it stands on an elevated spot overlooking the sea. It will contain 25 bedrooms. He has raised all the stone used in its construction from the rock-side just behind the structure. Near here is what is known as "Humboldt's Corner." The renowned traveller in question declared the views to be obtained at that spot to be the finest in all the world. The sea stretches on the right, a vast and fertile valley is at one's feet in front, and the great peak is to the left. Much pumice-stone is found on the mountain, and on the summit is a large deposit of pure sulphur. Going gently down the steep, one passes Santa Ursula, a small village with a little church in its midst. The latter contains a remarkable old pulpit of carved wood (about 300 years old, we thought). It is highly decorated with colour. Are there any painted pulpits in England save the one in St. Margaret's Church, Westminster, S.W., which the late Sir Gilbert Scott, R A., had decorated at the time of the general restoration, a quarter of a century or so ago? This rural church owns a remarkably good life-sized sculptured representation of the Crucified Christ, and a very old organ and organ-case. There are some exceedingly ancient instruments on the islands in the shape of organs. As a rule, the choirs occupy the western end of the church, and have a large reversible music lectern in their midst. Some of these are full of interest. One we particularly remember that had a strikingly carved crucifix rising from its centre. In the vestry at Santa Ursula is a curious old bier of painted wood, so constructed that the head of the coffin it contained when carried would be considerably elevated. It is canoe-shaped, and short poles at the head and feet protrude, for the bearers' use. We remember seeing three curious hand-biers in the cathedral at Throndhjem, in Norway, a few summers ago. They were dated 1765 and 1791 respectively, and were probably about as old as the one at Santa Ursula. But the Norwegian biers were very long, measuring over 20ft. in length.

The English Grand Hotel at Port Orotava stands upon a hill of lava, and is an immense building, containing 250 or 300 bedrooms. It is seen as far off as is the State House at Albany, U.S.A., and, to our minds, is just about as much too big. Near to it is the new English church, and not far off a well-designed stone mansion is in course of erection for Colonel Wethered, an English gentleman, resident, we learned, at Marlow. Its architect is Mr. Alfred Bovill, already referred to. Puerto Orotava lies down some hundreds of feet below the vast hotel. There are many quaint bits about this little fisher village. The groups of old houses and the colouring thereupon seen from the Mole struck us as being the most exquisitely beautiful we had ever met with anywhere. Villa Orotava is a few miles away, and although only a place of something like 9,000 inhabitants, is entirely lit by electric light. Here we had the pleasure of meeting Mr. Alfred Sax, of the firm of Messrs. Julius Sax and Co, the widely-known electrical engineers of West Smithfield, E.C.

The tall, slender date palms are marked features on the islands. The biggest is at this town, and stands 110ft. high. It is an old tree, and history records it was just the same height as it is now 400 years ago. Near to it there formerly stood an immense dragon-tree. Humboldt, who was born A.D. 1769, estimated its age at least 6,000 years. Its butt measured 48ft. 6in. girt 60ft. above the ground. It was 95ft. high. The original stem of these peculiar trees invariably rots away, and so the trunks are hollow. The interior of this particular tree was used for ages as an aboriginal temple, and after the Spanish Conquest Mass was sung therein. This tree was thrown down—we did not learn how—some eight-and-twenty years ago. An old chestnut tree hard by, which the Spaniards planted in A D. 1493, measures 27ft. 6in. girth. The dragon-tree is a native of Teneriffe, and its growth as remarkable as is that of the *Euphorbia Canariensis*, referred to in our last. The most venerable and the largest of the species at present existing on the island stands near the church at Icod, and is said to be over 3,000 years old. The broom, known locally as *retema*, grows up the hills to a height of nearly 11,000ft. The téa (*Pinus Canariensis*) and the native cedar (*Juniperus oxycedrus*) are the next hardy, and both thrive at an altitude of 8,000ft. The principal forest trees not already mentioned are the *venatico*, or native mahogany (*Persea indica*); the *palo blanco* (*Peccoma excelsa*), a hard white wood; the *til* (*Oreodaphne fœtens*), a hard dark wood; and the *barbusano* (*Phœbe barbusano*), another very hard and dark wood. The last mentioned has the reputation for being one of the strongest woods known. It is much sought after, for the beams of native wine-presses. Some species of gigantic heather grow 40ft. to 50ft. high, and girths 5ft. at their stem.

There are many other trees. Amongst them may be named the oak, plane, elm, cork, beech, cypress, umbrella pine (*Pinus pinea*), coral-tree, camphor, india-rubber, pepper, walnut, orange, vine, lemon, peach, pomegranate, apple, &c. In the island of Hierro, which we have already noticed as the most western of the group, there are no springs, and its inhabitants depend entirely on the rain for their water supply. There used to be a tree there called El Garoe, which, tradition records, distilled enough water from its leaves to supply all that was required. This is probably true, and if the site of the long since disappeared tree could be found, and some pines or laurels planted on the spot, it is not unlikely that the new trees would distil water also. Mons. Sanson, in his "Description of the World" (1670), refers to this marvellous tree (page 75), and says: "In this isle there is no fresh water found, only in the middle of the isle there grows a tree whose leaves are much like those of the olive, which, being always covered with clouds, drops from its leaves into a *cistern* which is underneath it very good water, and in such great abundance, that it suffices all the inhabitants, as also all the *cattle* and living creatures, in the island. . . . There is no fresh water, neither of *rivers*, *fountains*, *lakes*, nor *wells*, and without this tree it would be unhabitable. One Jackson, an Englishman, who reports to have seen, considered, and measured this tree in 1618, saith, that the water falls into a *pond* containing 20,000 tuns, which in one night is filled, and that from this *pond* the water is by divers channels conveyed into other *ponds* or *cisterns* through the whole isle, which is very well peopled, some say it hath in it 8,000. . . . Moreover, Jackson assures us that this tree hath neither *flowers* nor *fruit*, that it is on the side of a mountain, that it dries up in the day, that at night a cloud hangs over the tree, and that in the same time it distils its water drop by drop." But, "*Firdinand Suares* saith this tree bears a *fruit* like acorne, of a pleasant taste, and aromatick. . . . Most authors agree that its leaves are alwaies green, and compare them to the laurel."

Although there are no railways on any of the isles at present, a survey has been completed between Santa Cruz and Orotava (a distance of rather less than thirty miles), and it is possible that the scheme may be carried out with a light line at no distant date.

We will conclude these somewhat lazily jotted-down notes by a story told us by our state-room steward on our voyage home again to Devonshire's pleasant shores. The late Mr. Bull, of Belvedere Works, Southampton, will be remembered pleasantly by many readers as the energetic contractor for the late Mr. G. E. Street's Law Courts in the Strand. He also carried out a large contract in Cape Colony. The last time he was at the Cape, he met with some wood he took so great a fancy to that he had his coffin made of it, and brought it home with him. Our informant assisted Mr. Bull, when he came on board, to stow the not very pleasant-looking package, snug and taut, in his own state-room. When, not so very long afterwards—to the grief of all who knew him—Mr. Bull died, his remains were reverently deposited in the casket in question.

Harry Hems.

FOUNDATIONS FOR THE CATHEDRAL OF ST. JOHN THE DIVINE, NEW YORK CITY.

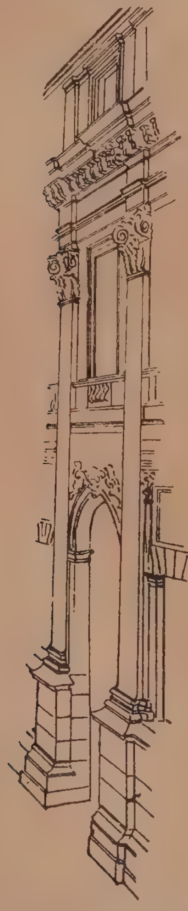
Progress has been made, according to the *Engineering Record*, in the foundation work of the Cathedral of St. John the Divine, New York City. The proposed cathedral will be one of the largest and finest ecclesiastical structures of modern times. The site is on the crest of a bluff overlooking a large part of Upper New York and the Hudson River. The church will be 520ft. long by 290ft. extreme dimensions, and of about the size of St. Paul's Cathedral. The foundations for the tower and adjacent choir are said to be well advanced. Much delay and expense have been caused by the unsatisfactory condition of the ground. The rock outcrops the site; but the excavations have revealed difficulties, owing to the surfaces of the ledges of rock being at a sharp angle, and to the inequality of the soil and softness in places, which rendered considerable excavation necessary. Several large pits were excavated, each containing the piers and other important foundations. The main piers at the crossing of transepts, nave, and choir for the main tower are thus dug out to the solid rock. The rock surfaces were dressed, cleaned with wire brushes and hose, and the space filled up to a maximum depth of 45ft. with concrete, upon the level surface of which the cut-granite pier footings are laid. The tower rests on arches sprung high in air, from four smaller corner towers with flying buttresses. Each of these towers is calculated to transmit a pressure of 17,000 tons to the bed of concrete, which supports its base 38ft. square, thus making a load of about 10 tons per square foot. To transmit this pressure equally the "concrete is composed of cement, sharp sand, and gravel, in proportion of 1, 2, and 3 respectively, mixed quite dry, and rammed by 20lb. rammers from 10in. horizontal layers to 8in. thick layers, and till the water was flooded to the surface." Each layer of concrete is treated like blocks of stone; between the layers that are rammed and left over-night a mortar of 1 of cement and 2 of sand is spread to give coherence between the layers. The concrete work is of unusual magnitude, and the mode in which the concrete is made, mixed, and rammed, so as to produce a homogeneous mass, described in detail in the *Record*, is remarkable. The plant and machinery for mixing the concrete and distributing it by means of trucks and derricks are admirably devised for the work.

CLASSIC DETAILS AND THEIR APPLICATION *

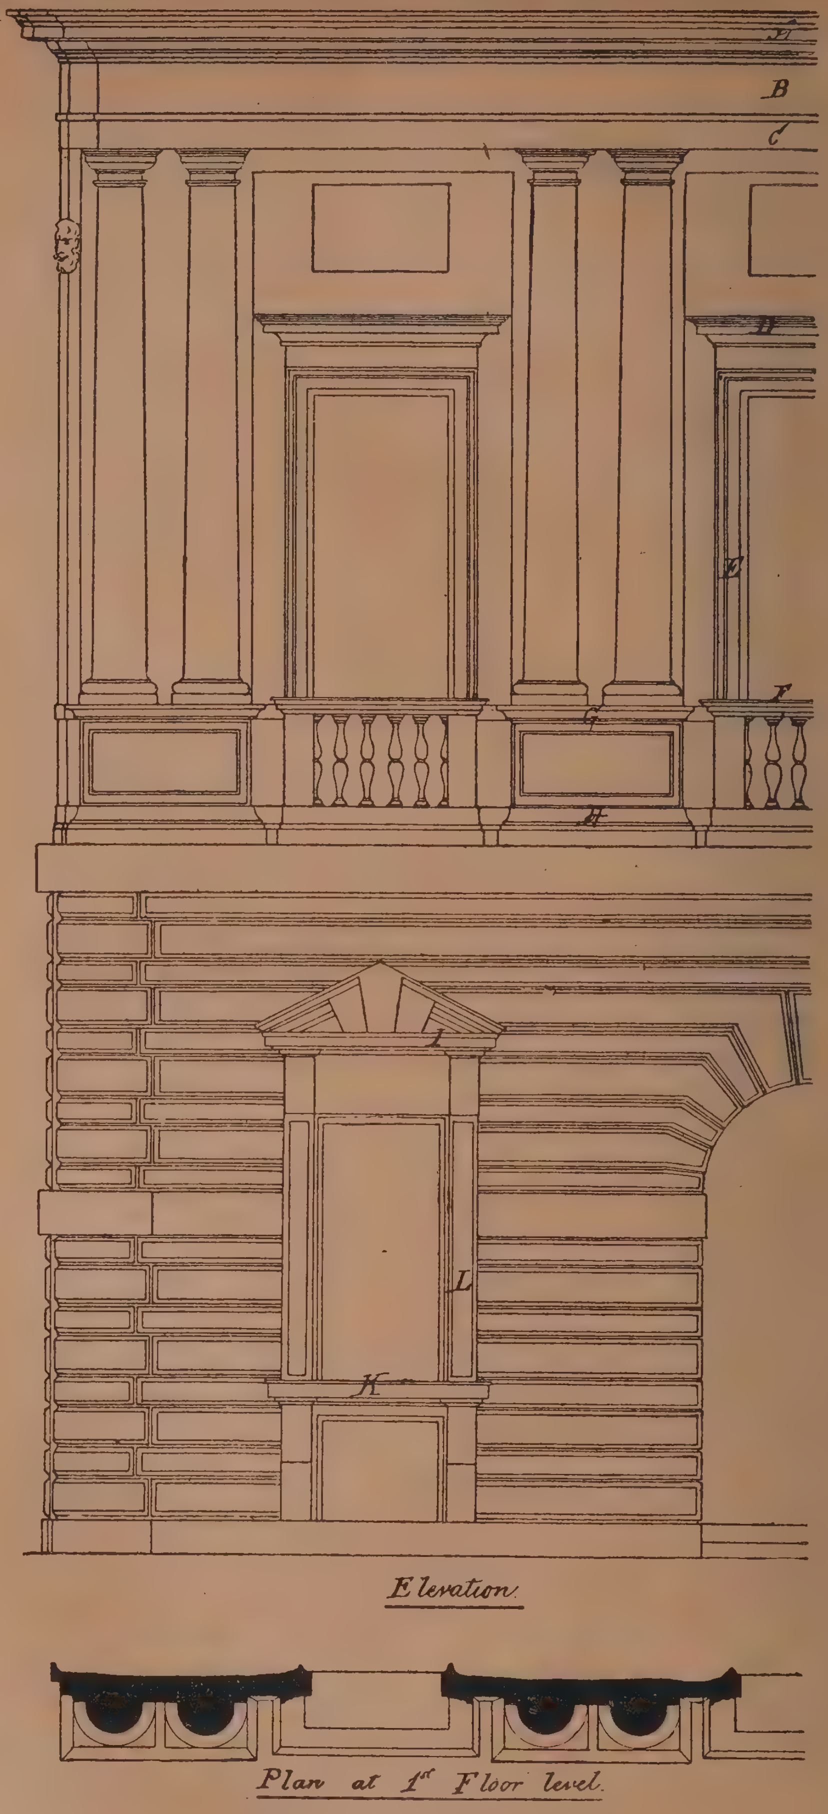
By G. A. T. Middleton.

VIII.—ITALIAN RENAISSANCE: BUILDINGS WITH SINGLE ATTACHED ORDERS.

THOUGH Raffael, in his Pandolfini Palace at Florence, had adopted the usual Florentine system of treating the Palace as orders, without the use of many parts, such as the columns, of which the orders would in Classical times have been more strictly considered to consist, yet when he built the Caffarelli Palace at Rome, he employed one complete attached order. This marks a new departure, and is one of the distinguishing points of difference, generally speaking, between the works of Florence and of Rome. Certainly, the Farnese Palace, of which there will be more to say presently, is treated in the Florentine fashion externally; but, generally speaking, complete orders, either single or super-imposed, are used for the sake of ornament, attached to the outer walling, but without constructional function.



Palazzo Valmarana, Vicenza.—Andrea Palladio. (From Schütz.)



Caffarelli Palace, at Rome. (By Raffael.)

In the example under discussion—the Caffarelli Palace—the lower story is heavily rusticated, with a plain band of stone to form its plinth, and another half-way up, inserted at the springing of the arch of the doorway, and still another, absolutely plain, but projecting rather more than those below, to act as stringcourse, and separating the lower from the upper story.

The cornice is not so deep as usual in comparison with the height of the whole building; and it will now be seen that, instead of proportioning it to the building as a whole, as had hitherto been the rule, Raffael had rather proportioned it to the Doric columns of the upper story, to which it more immediately belonged. With these columns, too, he took considerable liberties, both in proportion and detail, as compared with the work of the Romans, upon which all the Renaissance was founded. They are tall and slender, and are placed in pairs close together, with a considerable distance between the pairs, and each pair resting upon a surbase. The effect is perfectly harmonious, and allows for the introduction of windows, thus in every way carrying out the ideas of the Italian architects as to the employment of the forms of the more ancient architecture of Italy, to meet the needs of the buildings which they were called upon to erect; and it is characterised, as all the best work is, by extreme restraint, and the employment of the least possible ornament, to satisfy the needs of the case. The only carving upon the front of the Caffarelli Palace is the small mask on the corner, where there is usually to be found the coat of arms of the owner.

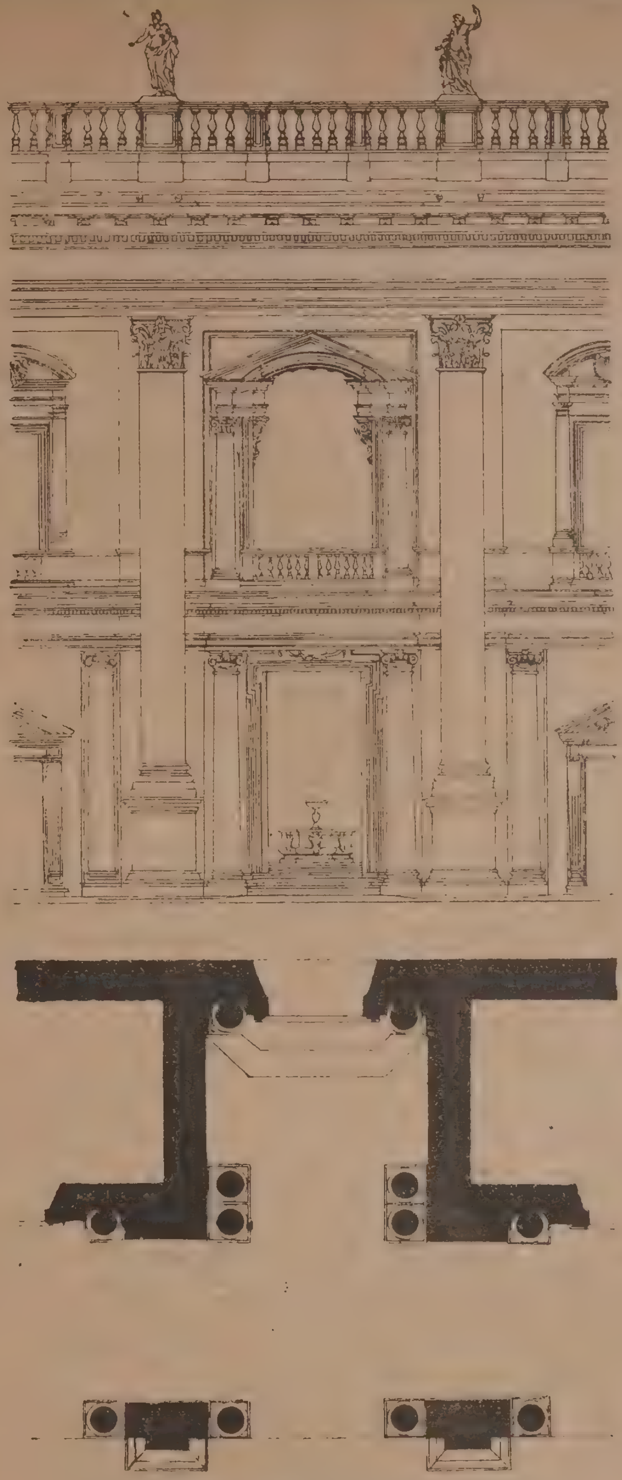
Mouldings from the Caffarelli Palace, Rome.
(By Raffael.)

A reference to the details will show upon comparison considerable difference between the treatment of the mouldings of the Romans and by their successors of the Renaissance. There is the same use of the circle and its segments, but with considerably greater freedom and a higher appreciation of the exact part which each moulding is to play. Each one seems to have been most carefully thought out, having regard to its position, above, level with, or below the eye; and particular attention may be directed to the frequent use of the cavetto, and to the very different curves which are given, both to the cyma recta and to the cyma reversa, wherever they are used, as in mouldings A and D.

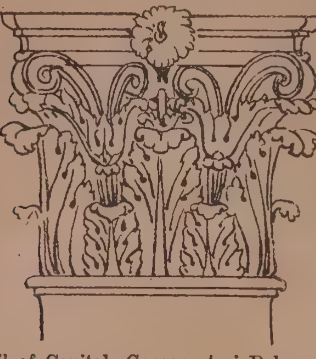


Courtyard of the Conservatori Palace, in Campidoglio, Rome.
(By Michael Angelo.)

The employment of single attached orders is generally considered rather a sign of Venetian than of Roman work, and correctly so. Single orders were there introduced by Palladio, and greatly used both by him and his successors, often comprising the entire height of a building, and including several stories. This carries off the cornice well as proportioned to the whole building, for at the same time it is proportioned to the attached order; but the separation of the stories is, of course, not so well marked, and a vertical tendency of the general lines becomes prominent to an extent which is not usual in architecture of the Classic type. In the Valmarana Palace, at Vicenza, which may be considered to be fairly typical, tall Corinthian pilasters rest upon a deep plinth, and are continued through the two lower stories of the building. They carry the main cornice, which, though rich, is plain compared with the Corinthian cornices of the Romans, and is destitute of carving. Above this, however, in this instance, there is a third, or attic, story; but the building would have been complete as an architectural composition without it.

A very similar method of treatment had been attempted by Michael Angelo in the courtyard of the Conservatori Palace, in the Campidoglio, Rome; but the Corinthian pilasters there hardly give the effect of carrying the cornice, and the result is by no means so good as it generally is in the work of Palladio and his followers. Analysis of the cause shows the pilasters to be too widely spaced—too weak for the task imposed upon them—and the pedestals upon which they rest is but a poor substitute for the continuous plinth. The rich effect, however, of the constructional

Ionic order to the lower story, carrying the intermediate cornice, which the main pilaster interrupts in crossing, is a point well worth attention, and a detail of the pilaster capital is appended for comparison with the capital of the Pantheon, illustrated on p. 40 of the Building News for July 12th last, in order to show how closely in such respects the Renaissance architects followed their models of earlier times.



Detail of Capital, Conservatori Palace, Rome.

CAST IRON IN BUILDER'S AND CONTRACTOR'S WORK.—I.

By Joseph Horner.

Cast iron, though now so common, is a comparatively modern product; that is, its history is very much more recent than that of malleable iron, or of steel. The latter were known two thousand years ago. Cast iron was not used as a definitely distinct product of manufacture until the later Middle Ages. In some parts of Africa the iron reduced by the native smiths is identical with that which was manufactured a couple of thousand years ago—that is, either malleable, or steely, not fused or cast. The peculiarity of the products of the primitive furnaces, of the Indian and African forges, and of the Catalan furnaces, is, that from the same furnace, and even from different parts of the same charge, malleable iron and temper steel can be produced at will, dependent on the conditions which the smelter desires to set up. Cast iron, however (which differs from malleable iron and steel mainly and essentially in the presence of a larger amount of carbon, and of some other foreign elements), is not produced by these methods. In these, small quantities only of ore are reduced at once. The heat is not sufficient to cause fusion, but only a pasty condition of the resulting bloom, and the product is either a soft, or a steely iron, according to the proportions of fuel and ore used, the nature of the blast supplied, and the duration of the process.

It does not seem at all clear when, and how, the knowledge of the production of cast iron as a distinct product first came about. Statues of cast iron are mentioned by Greek writers, but none are known to be in existence, and it is difficult to understand how they could have been cast at all, because the rude hearths of India and Africa, which are probably practically identical with those of earlier ages, are not capable of producing a liquid product. More than one modern writer has contended that the knowledge of cast-iron ante-dates the Christian era; but the evidence adduced is wholly documentary, and though iron corrodes so readily, that would not account for the total disappearance of all heavy masses, such as pigs, and statues. Probably the earliest known casting is a tombstone—the incongruity must be pardoned—in Burwash Church in Sussex, which dates from the 14th century. Sir I. Lowthian Bell places the introduction of the blast furnace between the years 1556 and 1618, because the work of Agricola, published in the former year, contains no allusion to it, and the work of Dud Dudley, published about the latter year, mentions mottled and grey irons. But the Prussian Stückofen furnace, described by Agricola, was a Catalan furnace extended into a shaft, in which iron could be liquefied, as well as rendered malleable, and this, taken in conjunction with the existence of the 14th-century tombstone, seems to show that the knowledge of cast iron might have been about contemporary with Chaucer. Henry Poole, in a paper contributed to the Royal Society in 1676, alludes to the pig-iron as being taken from the high-blast furnace to the open hearth charcoal refinery. So that the making of cast iron was a recognised industry at that time.

It was evidently not until the device of erecting a shaft over the ordinary furnace was adopted that the regular production of cast iron was possible. By such a device the draught would be increased, and the iron liquefied. Whenever that was effected, the art of casting in iron was inaugurated, and the utility of the metal became capable of indefinite extension. But its manufacture was long limited by the practice of smelting with charcoal.

The earliest uses for cast iron were the manufacture of cannon and balls, replacing the old "gun-stones" alluded to by Shakespeare, and the old andirons or fire-dogs, and grate-backs and railings. Many of these still remaining attest to the skill of the early founders. The iron railing round St. Paul's is one of the earliest extensive works in cast iron. Sixpence per pound was paid for it, the total cost being £12,000. It would not cost a penny a pound now. The rails were executed by several contractors, but the bulk was cast at Lamberhurst, near Tunbridge Wells, in Sussex. The first English cast-iron cannon were made at Buxtead, in Sussex, in 1543. Some of the earliest cannon made in England are still preserved in the Tower grounds. The industry grew so rapidly that in the reign of Elizabeth iron ordnance was exported, whereas formerly it had been imported. Sussex became the chief locality of the new industry. In the reign of James I. about one-half of the iron produced in England was manufactured in Sussex. But this received a check by the laws passed to prohibit the felling of forest-trees, which were required for the renewals of England's navy and for other purposes. Since all the cast iron at this period was smelted with charcoal, the ironmasters migrated to other parts of the country, or were ruined. The first Act, prohibiting the destruction of forests within 14 miles of London for iron making, was passed in 1581. Other Acts followed from time to time, until finally, as a result, the Sussex iron industry died out entirely about the close of the 18th century.

It was not until the discovery by Dud Dudley that iron might be smelted with pit-coal that the industry could truly be said to have been born. Dud Dudley's first patent for smelting by means of pit-coal was taken out in 1620. It was renewed in 1638. But the iromasters did their utmost to ruin his trade, and being also an ardent Royalist, he became involved in the troubles of the Revolution, and died, a disappointed man. The iron industry still declined, until in 1725 its production had fallen to less than 13,000 tons. But at about that period Abraham Darby, 1720-1733, was working on the lines inaugurated by the unfortunate Dud Dudley. Darby substituted charred coal, or coke, for coal, and made a fortune. Darby's first success was in the making of cast-iron pots for domestic use, which, previous to that time, had been mostly imported from Holland. He started the Coalbrookdale works in Shropshire in 1709, and turned out other light ironwork besides pots, using at first charcoal only. But the industry was slow in recovering its lost ground. Even in 1740, only 17,350 tons of pig-iron were produced in Britain. In 1788, the product had risen to 68,300 tons, and three-fifths of this was still smelted with charcoal. At this period the cost of pig was from three to four times its present price. At the beginning of the present century it ranged from about £6 to £9 per ton. In 1825 it reached its highest mark—£12 per ton.

The discovery of the Blackband ironstone in Scotland, in 1801, by David Mushet, in which the ore and fuel necessary for the extraction of iron exist in combination, marked an important epoch in the history of the Scottish iron trade, as well as in that of other districts in which the same formation occurs. In 1828, the hot blast was invented by Neilson, and within four years of this the firm at the Clyde works in Scotland were producing twice as much iron as previously with the same expenditure of fuel. The hot blast then used was at a temperature of only 600° Fahr., or about half the temperature now employed. The real era of cast iron dates from this period. Thenceforward the manufacture of cast-iron articles grew steadily. The Sussex blast furnaces were only capable of producing from three to four tons per week, while a modern furnace will turn out 550 tons or more. Without the invention and growth of the steam-engine and the manufacture of powerful blowing engines, the development of the iron industry would have been confined within narrower limits; but these have developed concurrently, and superseded the old water blast used with the primitive furnaces.

But with each step in the growth of the iron manufacture the quality of the product has deteriorated. The iron and steel of the rudest primitive furnaces has never been surpassed, and is seldom equalled. The quality of average cast iron has never been worse than it is to-day, and it is fortunate that wrought iron and mild steel are capable of being substituted for it in all structures where great strength and reliability are essential. As the subject of wrought iron and steel does not concern us in these articles, I make no allusion to the various steps in the growth of these industries.

After the smelting of cast iron from the ore with pit coal had become an industry, almost every piece of structural work which could be made in iron was made in that material, timber being the alternative structural material. That was the era of cast-iron bridges, many of which still remain, testifying to the excellent quality of the material then smelted by the cold-blast process. The first cast-iron bridge made in England was built by a grandson of Abraham Darby, at Coalbrookdale. It was erected over the Severn at Broseley in 1779. The span is 120ft., and it is still in existence. The facility with which the molten iron could be made to assume any required form, and the large masses in which it could be cast, caused it to be employed for all conceivable classes of work, both structural and ornamental. It was not until after the inventions of the Craneges, of Onions, of Cort, and Hall, by which the production of malleable iron was rendered practicable in much larger masses and in forms which could not be produced at the hand forges, that the use of cast iron for some purposes for which it has been previously used began to decline. The elasticity and ductility of the new material gave to it such distinct advantages for certain classes of work that it began to supersede cast iron for those classes of work, just as to-day mild steel is superseding—perhaps I ought to say has superseded—wrought iron for the same kinds of work, and for the same reasons. But the operation of the first named went on much more slowly than that of the latter, because of the high excellence of the cold-blast iron. After the introduction of the hot blast the quality of the product deteriorated simultaneously with an increase in the masses in which wrought iron could be rolled, and this concurrence of circumstances accelerated the displacement of the former by the latter. And, most unfortunately, cast iron has received much ill-deserved discredit because of the dishonesty of some greedy manufacturers, who have not scrupled to risk safety and reputation for the sake of excessive gain. I have had to do with cast iron all my life, and I say unhesitatingly that for certain purposes it is a splendid material; a better material than any other; a material which is, as far as our present knowledge goes, never likely to be displaced by any other. But then it needs to be used and treated intelligently. So much depends on the design, on the practical details of the work itself, that a man is scarcely qualified to inspect, or to form a reliable judgment on cast-iron work, unless he has been practically engaged in such work. I will give illustrations of what I mean in the course of these articles, in which I propose to treat of the nature, properties, and uses of cast iron, the essential differences between sound, good, and reliable castings, and those of an opposite character, and of the methods by which one may be distinguished from the other.

◆

PRACTICAL RIVETING.

Rivets play precisely the same *rôle* with respect to iron and steel work as bolts and spikes do in carpentry, and screw and nails in joinery work. The object in all cases to be attained by their employment is the prevention of all relative motion among the separate parts of the metallic girder, timber frame, or piece of furniture which they bind together. In the particular instance under consideration, the stress takes the form of a direct shear, in a direction probably at nearly right angles to the axis of the rivet. This shear is clearly due to the tendency of the plates, bars, or other sections of iron which are riveted up to slide one upon the other. Recently some very interesting and valuable experiments have been carried out in connection with the whole question of practical riveting, which throw a fresh light upon some points which have always been regarded with some doubt. During the actual operation of riveting, when cooling, being "closed," and occasionally under other conditions, rivets are exposed to tensional stresses of a very severe character, in some cases even exceeding the original elastic limit of the material itself. Whether the iron or steel work be punched or drilled, or whether hand or machine riveting be used, there is but one result to be effected. It is quite possible, although it may read a little paradoxical, that a rivet may, in the discharge of one part of its duty, so act as to completely nullify or prevent any shearing stress upon it whatever. In order to fully understand how this can occur, we must examine what takes place during the actual operation of riveting. Should machine riveting be used, it is especially necessary to take the precaution of bringing the bars, plates, or other pieces into fair contact by means of temporary bolts. No great pressure need be exerted, but sufficient to bring the two pieces well "home." If this preliminary precaution is neglected, as it sometimes is, the rivet metal will be squeezed out between the interior surfaces of the plates or bars, instead of filling the rivet-holes. The result of this intrusion of material in the wrong place is that a ring or small collar becomes formed on the shank of the rivet, and the two pieces cannot be brought together until the bulge be removed. Under the most favourable circumstances the cutting-out of rivets is not a job to be desired, and all practical riveters are aware of the difficulty and extra trouble involved in cutting out rivets which have been put in by hydraulic machinery. It is also certain that if the plates or pieces to be united are thin, their condition is not improved by the unavoidable slogging and hammering to which they are exposed.

When a rivet, either in machine or hand-riveting, commences to cool, it also commences to contract, with a force proportional—although not in a direct ratio—to the temperature to which it was raised. This contraction is evidently, mathematically speaking, of the third order—that is, of a cubical character. In a lateral sense—that is, in a direction transversely to the geometrical axis of the rivet—it is not exactly favourable to good riveting, since its tendency is to prevent, although to a very small extent, the complete filling of the rivet-holes. Great stress is, and always has been, very properly laid upon the importance of rivets thoroughly filling the holes in which they are inserted, but there is no evidence of the failure or collapse of a bridge girder or roof truss resulting from rivets not filling the rivet-holes. In the recent experiments to which we have already alluded, one of the conclusions arrived at was to the effect that rivets do not fit exactly—that is, absolutely and completely fill the rivet-holes. Even if we assume this assertion to be universally true, it must not be forgotten that there is a great difference between a rivet which fills the rivet-hole in the practical sense of the term, and one which does not, and is called a loose rivet. In steel and iron constructions subjected to the impactive action of heavy moving loads to shocks and jerks, and to "reversal" of stresses, many of the rivets undoubtedly work loose after some years of wear and tear. There is another direction in which the contraction of rivets, while cooling, exercises a very beneficial effect upon the security of the joint, both as regards the rivets themselves and the parts of the structure they unite. This is the contraction in the direction of the longitudinal axis of the rivet, which, through the medium of the rivet-heads, grips the pieces joined together like a clamp or vice, with a pressure which it is impossible to estimate or measure with any degree of exactitude. The greater the pressure thus exercised the greater becomes the friction between the plates—assuming for the sake of simplicity and conciseness that plates are the parts to be united—and their resistance to the sliding of one plate upon the other is also proportionally augmented. If there were no friction between the plates, they would, when under stress, tend to slide, and shear the rivets. It is therefore evident that the greater the friction, the less is the shearing force and the stress on the rivets. In a word, they are inversely proportionate to one another.

It is quite possible, and very probably frequently occurs, that the grip, or vice-like squeeze of the rivets upon the plates, assumes such a high degree of intensity as to increase the friction to an extent which virtually prohibits all sliding of the plates one upon the other. Under these circumstances the frictional resistance of the plates is so great that it can take up the whole stress upon them, and the shearing strength of the rivets is not called into play at all, as was stated at the commencement of our article. But as the amount of this frictional resistance between the plates is quite uncertain, no reliance can be placed on it, and in calculating the strength and dimensions of riveted joints it should never be included in the calculation. The reader will find full information respecting this subject in our articles on "Riveted Joints" in the Building News, 1893 and 1894. Another reason for neglecting the frictional resistance of plates is to be found in the fact that whatever may be its initial intensity, it diminishes in the course of time, especially in the case of structures exposed to sudden and frequent vibration. The variable nature of the resistance to sliding is due to several causes. One is the temperature at which the riveting is commenced, continued, and completed. The last stage, or that in which the rivet is "closed," has to be attended to with particular care in the case of steel rivets which are put in by hand, as they will not stand the hammering and knocking about at a low red heat with the same degree of impunity as their iron brothers.

Again, the material itself of which the rivet is composed exercises a considerable influence upon its contractile power, as also does the method or system of riveting employed. Although, as previously stated, there are no means of measuring with absolute accuracy the limit of the resistance to sliding, it varies nevertheless with the limit of the elasticity of the material of the rivet. Should the stress upon the rivet, in its plate-gripping effort, exceed the limit of elasticity, it will gradually lose its hold, though not altogether. It was ascertained in the experiments under notice that in some instances where the rivet-holes were drilled and machinery employed for riveting, the pressure culminated in a resistance to sliding which was nearly equivalent to an actual weld.

It is usual, and indeed necessary, when designing a riveted joint to take into consideration the different, or at least the principal different, ways in which the joint might fail. Otherwise, the length and thickness of the wrappers, as well as the number of the rivets, could not be arrived at. The theory that the rivets might hold on one side of the joint, while those on the other side were either sheared through or the plate torn, is not confirmed by the late experiments on the failure of joints of this description. It was found that where there were several rivets, as there are in all ordinary joints, they all fail together, the yielding of the first one or two entailing the destruction of the others. In another respect the experiments fully bore out the well-known practical rule, that the ultimate shearing strength of rivets per square inch of sectional area is not less than three-fourths of their ultimate tensile strength. Since the frictional resistance of the plates counts for something, we, in our calculations, adopt the same factor for both kinds of stress, which is more simple, convenient, and quite sufficiently accurate. It may be mentioned that rivets may yield a little, without all at once jeopardising the safety of a structure; but the partial failure ultimately conduces to their general deterioration, and affects the life and durability of the bridge or girder. In all experiments connected with the testing of rivets, or of riveted joints, all holes should be drilled and hydraulic machinery employed. Where steel is the material under trial, punching the holes should never be employed unless the plates or bars are very thin. Although drilling is not attended with the disadvantage of injuring the material round the rivet-hole, in the manner in which punching does, yet the drill leaves a sharp edge which should be slightly rounded off, or it will tend to facilitate the failure of the rivet by shearing. One of the chief practical advantages of machine riveting is the regulation of the pressure, and the general control which it allows the workman to have over his work.

◆

BOOKS RECEIVED.

Diphtheria and its Associates, by Lennox Browne, F.R.C.S.Ed. (London: Baillière, Tindall, and Cox).—The volume before us is based on a course of lectures delivered by Dr. Lennox Browne, in which their author emphasises "the desirability of assimilating the teachings of bacteriology to the purposes of practical medicine." Clinical observations, as he shows, gain additional confirmation, and are often corrected by the light of bacteriological science. We can only give the titles of the chief chapters, which are illustrated by many beautiful photomicrographs. The history of diphtheria forms the first chapter, in which the learned author considers the many hypotheses as to its origin. The differentiation of several allied maladies has progressed of late years, and these are noticed. The etiology, the predisposing causes, are also entered into at some length; after which chapters on the pathology; bacteriological diagnosis of diphtheria, and its associates; clinical diagnosis of the disease; the treatment of diphtheria; croup; remedies in diphtheria and the serum treatment, are given. The great value of the facts brought forward by the author, and the opinions he deduces therefrom, cannot be overrated. The latest views are recorded, and the author lays down the lines of a safe middle course in the treatment of this formidable disease.——*Glossary of Technical Terms used in Architecture and the Building Trades*, by Gavin James Burns, B.Sc. (London: E. and F. N. Spon), is a useful compilation, based on the author's instructions to the students attending his classes in building construction. The definitions are short but concisely stated, and would have been rendered more useful by a few more illustrative diagrams. For the student's use this glossary will be found of value.——*The Law Relating to Building Societies*, by Edward Albert Wurtzburg, of Lincoln's Inn, Barrister-at-Law. Third edition (London: Stevens and Sons, Ltd.)—This edition has been thoroughly revised and brought up to date. The law relating to building societies has been amended, and several decisions have been given which have thrown new light on the law. The appendices contain the several statutes relating to incorporated societies, the building society regulations of 1895, &c. In this volume the author treats of the formation of these societies, their purposes and powers, the rights and liabilities of members, mortgages to building societies, settling disputes, winding up, and other questions which have more than general interest just now. The book is well printed, with marginal headings, and is furnished with a complete table of cases and a copious index. Everyone who is a member of a building society, or is officially connected with one, ought to possess this compendium of the law, a knowledge of which would save many mistakes and heartburnings.——*Transactions of the American Society of Civil Engineers* (May) comprises a few instructive papers. One is by Mr. Herbert M. Wilson, M.Am.Soc.C.E., on the "Topographic" map of the United States, which describes in detail the methods employed by the U.S. Geological Survey on this work, which is being proceeded with simultaneously in all portions of the country. The triangulation executed in the field is clearly shown by a map. It was done on the plane-table board. The red lines represent the various sight-lines from one occupied station to another. Heavy red lines indicate the three primary triangulation stations—Giant Mountain, Hurricane Mountain, and Blueberry Hill, which are connected by straight lines. Tertiary locations are also represented. Vertical angles were taken to all of these points, and their elevations computed within a few feet. Meanwhile, assistants are carefully traversing all roads, using a light form of plane-table, having no levelling apparatus, on which is a compass needle. The distances are measured by the odometer on the wheel of the buggy on which they ride, and every road in the area is thus surveyed. Fore and back sights are taken, and lines are plotted to prominent objects—as hilltops or buildings. In this way the assistant connects his work with that of the topographer, as he locates all houses on the lines of traverse. This work is plotted 1 mile to 1in. It is stated the average traverseman covers about 12 miles a day. The plates illustrating the triangulation are admirable specimens of colour engraving. To all interested in survey work this paper is of interest. *Management of Highways*, by E. Parnell Hooley, Assoc. Mem. Inst. C.E. (London: Biggs and Co., Salisbury-court, E.C.), is a useful brochure, originally prepared as a paper read at a conference of the new Urban and District Councils of Notts, in 1895. Mr. Hooley has attempted to bring before his readers the practical bearing of the clauses of the Local Government Act, 1894, on highways, and the powers and duties imposed on the new District

Councils by the Public Health and General Highways Acts. The author, who is county surveyor of Nottinghamshire, usefully applies the practical experience gained by the county council of this county, for the benefit of other authorities. He points out the many defects of previous mismanagement, such, as applying material at the wrong time of the year; want of skilful application of materials; "starving," and use of improper materials; false economy and insufficient manual labour, and of not having supply of such labour regularly. These several defects are explained, and will be usefully read by all highway authorities. The author also deals with the system of book-keeping, and shows that the chief defects in the accounts is the "absolute impossibility of tracing the cost of a particular road for any purpose, and the consequent trouble to obtain any information of a reliable nature as to checking waste or improper expenditure." The list of books or accounts that are necessary for audit are given: wages book, materials account book; team; tradesmen's bills, and miscellaneous expenses for repairs. Mr. Hooley points out the defects of the present system of accounts, such as the ordinary "materials" book, which gives no check on the weight, cartage, or place of deposit, only of amount of material supplied. The system of book-keeping and forms in use in Notts are given, and these are kept in the surveyor's office. The value of this little book will be found in the specimens of pages of Manual labour book, Team labour daywork, Materials account book, &c., which give the various headings and columns; also forms of tender for day and piecework, for materials, &c. Other valuable details are given, such as the form of county surveyors' cash book, memoranda of agreement between contractors and county council.——*The Management of Dynamos*, by G. W. Lummis-Paterson, Electrical Engineer (London: Crosby Lockwood and Son).—This little handbook is intended for the use of mechanics, engineers, students, and others who have, or will have, the charge of dynamos, and who wish to know the theory and principles of their construction. The theory of the dynamo is first described, then the construction and action of the various kinds of dynamos, and lastly the practical working and management. The diagrams are numerous and clearly drawn, and the chapters are divided into sections of marginal headings. The magnetic principles are well explained by the aid of illustrations of the magnetic field, solenoids, curve of saturation of the electro-magnet, the cutting lines of force of conductors. The types of armatures are illustrated and described, and the author gives a very full explanation of the principles before he discusses the practical working and management of dynamos. We can safely recommend this handbook to all students and engineers. *Notes on Shippo: a Sequel to Japanese Enamels*, by James L. Bowes, author of "Japanese Pottery," &c. (London: Kegan Paul, Trench, Trübner, and Co., Ltd.)—The author of this work is well known for his researches into the history and manufacture of Japanese wares. The information here collected in volume form was first intended for a paper to be read before the Japan Society. Mr. Bowes, in his "Japanese Enamels," describes the art of *cloisonné* enamelling, and in these "notes" he records valuable information upon the subject which has since come into his possession. In the work on enamels, he said: "The Japanese themselves designate these works as *Shippo* ware, meaning that they represent the seven precious things—namely, gold, silver, emerald, coral, agate, crystal, and pearl." The *cloisonné* and the *champlevé* enamels are described, and the three well marked classes. Shippo-working is intimately associated with glass-making, and the author describes the latter process, and several examples of Shippo. The earliest example is a "mirror said to have belonged to Emperor Shomu, whose reign commenced 724 A D. It is known as the *Kingin juniyo*, the mirror, with 12 leaves of gold and silver, the back of which is *shippo yaki*." Mr. Bowes gives an illustration of this mirror. It is of polygonal form, and is divided into 12 leaves outlined in wire and filled in with glass. The back has a frame of gold wire in the form of a flower, which is filled up with various-coloured glass. We have no space to refer to other examples, nor to the conclusions of the author, which are of interest to the collector and student of Japanese enamels. Some admirable photos are given of the work of the *Hirata* family, who are the only *shippo* workers whose names are recorded in Japanese textbooks.——*Contractors' Price-Book for* 1895, by Edward De Vere Buckingham. (London: Bigge and Co., Salisbury-court, E.C.) The combination of prices with formulæ, patented appliances, and data for calculation is a desideratum. The compiler of this thick and compendious volume has produced such a book at a reasonable price, which will be found of use to all architects, engineers, and contractors. The author has incorporated in a well-printed volume practical data, calculations, and memoranda on the various trades, which must be of considerable help to all contractors and others engaged on large works. In another edition no doubt many omissions will be supplied. Under the important branch of "Excavator" we have not only the prices of every class of work, the weights of earth, natural slopes of earth, formulæ for ascertaining cost of excavation per cube yard, bulk of excavation after removal, cost of filling, of wheeling; notes on tunnelling, pneumatic foundations, rock drills, blasting, air locks and hoisting gear, hydraulic construction, dam and reservoir construction, plant for sinking cylinders in river beds, bridge excavations, and foundations, cylinder piers, canal works, formulæ for discharge of water (Kutter's, Bazin's, and others); stone-breakers' pulsometer and other tools and appliances, sinking wells and shafts, &c., &c. The other trades are similarly treated. To engineers and general contractors Mr. Buckingham's Price-Book will be found invaluable.——*Proceedings of the Engineers' Club of Philadelphia.* Several papers appear in the July number of this journal. One on the "Methods of Stream Measurements by the U S. Geological Survey," by Mr. F. H. Newell, is of interest. The hydrographic division of the Geological Survey has great value and interest, and the author of this paper describes various instruments and methods used in measuring the flow of water, the relation of height to discharge. Tide gauges are of value when under the care and supervision of skilled men. They are simply vertical rods fastened and marked in feet and tenths. Inclined rods are used for the slope or bank, these being marked to equivalent vertical feet. Current-meters are constructed in several ways. The float is generally used, but the meter is preferred, though no one meter has been found to be generally applicable. Mr. Newell describes and illustrates cup-shaped meters used for shallow streams and for canals. The wheel must be held horizontally, or the velocity is recorded too great. The Haskell meter, made with only two flukes on the revolving wheel, is used for torrential streams, and can be used either on a rod or suspended by a cord from a bridge. It records electrically. Illustrations of this form of meter are given. Meters are generally handled from a boat, bridge, or pulley-suspended car, carried by a stretched cable, in which car the hydrographer sits. Measurements of discharge for various heights of water are plotted upon cross-section paper, on which the distance from base corresponds to height of water, and the distance from left to right to the volume of stream or "discharge in second-feet." The author gives diagrams of daily discharges plotted graphically, and the names of streams and rivers. The Potomac, Owyhee, Arkansas, and other river discharges are shown graphically. The paper is full of instruction to all students of hydrography and those who are interested in stream measurements. Other papers are on "Electric Heating," "Cribwork Cofferdam," "Wreck of the Connersville Bridge," "Manual Interlocking of Railroads," &c., and are all illustrated.

DEPARTMENT OF PUBLIC WORKS, NEW SOUTH WALES.

We have the report (Blue-book) of the Department of Public Works, New South Wales, for 1893-4. The report of the Government architect (Mr. W. L. Vernon) gives a long list of new buildings completed at Sydney during the year 1893, comprising the Central Police Office, at a cost of £40,546; fire-brigade station, at £11,069; general post office, clock, &c., £6,167; lands office, £141,153; public works office, additions at, £54,926, &c., &c. The phototypes give illustrations of Sydney Hospital, lately described in our pages, also the Lands Office, Sydney, an important and monumental-looking building in the Italian style; bridge over the Darling river, with lifting section; wrought-iron aqueducts, Walli Creek; saddles for carrying pipes over Cook's river; also plans of Sydney Hospital, details of timber trusses, Wentworth Bridge, details of towers and machinery, western suburbs sewerage, maps, &c. The progress of this enterprising colony in architectural and engineering projects is fully recorded in this voluminous report.

CHIPS.

In Rome the excavations round the Colosseum have brought to light the remains of the ancient portico which formed part of the façade of the Baths of Titus.

The reopening of the Wesleyan Chapel at Montgomery took place on Sunday week after restoration. The alterations have comprised improvements to the pulpit, porch, and Communion rail, and the provision of a vestry, the architect being Mr. Potter, Welshpool, and the tradesmen employed—Mr. T. Lucas, painter; Mr. T. Marsby, gasfitter; Mr. T. H. Evans, carpenter; and Messrs. J. Jones and Son, stonemasons.

The corporation of Southampton have adopted plans by the borough surveyor, Mr. W. B. G. Bennett, for the erection of a four-cell refuse destructor and the installation of two water-tube boilers for use in connection with sewage pumping plant; and also for the construction of mixing chambers for sewage treatment at the Platform.

At the church of St. Thomas, Northaw, Herts, on Sunday week, a fresco and stained-glass window was dedicated. The fresco is in the north transept, and represents Christ charging His eleven apostles to make disciples of all nations. The window, which is on the north side, completes a series of three, two of which were dedicated a few months ago. It represents the Parable of the Talents. The windows, frescoes, and decorations have been carried out by the firm of Messrs. Heaton, Butler, and Bayne, Mr. Hegerty being the fresco artist, and Mr. F. Barron having had charge of the remaining mural decoration.

In the 14th-century church of St. Faith, Bacton, Herefordshire, which was reopened after restoration 15 months since, an organ, built by Messrs. P. Conacher and Co., of Huddersfield, was opened last week.

The ceremony of laying the foundation-stone of the extension of the Esplanade took place at Lynmouth on Friday. The work of extension is being carried out under the Lynton urban district council, who have let the contract to Messrs. Jones Bros., of Lynton. It is intended that the Esplanade shall now be carried out a quarter of a mile further than at present, as far as Riddiball. The sea wall, which will measure about 10ft. in thickness at the base and 8ft. at the top, will start from the finish of the old Esplanade wall, and run off in the direction of an obtuse angle. The estimated cost of the work is £3,000. The stone for building purposes is being taken from the cliff.

At the last meeting of the Sheffield town council a communication was read from the Local Government Board, granting the application of the council to borrow money for the purposes of the widening of Angel-street and Castle-street. The board agreed to the borrowing of £50,000 for 50 years, £2,000 for 10 years, and £14,000 for one year.

A chancel is about to be added to St. Mary's Church, Todmorden, from plans by Mr. Medland Taylor, of Manchester.

Barrow Church, near Wenlock, was reopened after restoration on the 7th inst. In the porch is a tablet bearing the following inscription:—"The restoration of this church was commenced by the Rev. the Right Hon. Orlando Watkin Weld, 4th Baron Forester, and completed to his memory by his wife, Emma Lady Forester, 1895." The architects were Messrs. Christian and Purdy, Whitehall-place, London; the builder, Mr. C. T. Smith, Broseley; and the clerk of works, Mr. R. Dick.

A monument is to be erected in Quebec to Samuel de Champlain. Artists, sculptors, and architects are invited by the local committee, of which Mr. Ludovic Brunet is secretary, to send in models, plans, or drawings before Jan. 2 next. The cost of the memorial is not to exceed 30,000dol. Copies of the conditions may be obtained on application to the High Commissioner for Canada, 17, Victoria-street, S.W.

The foundation-stones of a new English Congregational church were laid on Friday at Cocklebank, near Bagillt, Flintshire. The new church (which is to replace the present dilapidated one) will be the only English place of worship within two miles of Bagillt. It is to be of red brick, in the Gothic style, with seating accommodation for 300, and will cost about £700. The architect is Mr. Parry, Rhyl, and the contractor Mr. T. W. Sibeon, Holywell.

HENRY THE EIGHTH'S GOLDSMITH, BY HANS HOLBEIN.—THE DINING-ROOM IN THE OLD HOUSE OF LORDS, BY JOSEPH NASH.—BISHOPSGATE HOUSE, E.C.—HALL OF RESIDENCE, UNIVERSITY COLLEGE, ABERYSTWITH.—OLD HOUSE AT TEWKESBURY. — LYCH GATE, SHANKLIN. — FRENCH MEDIEVAL AND RENAISSANCE FURNITURE.—ELEMENTARY SCHOOL, PYRTON, OXON.—AN AMERICAN DOUBLE COTTAGE.

Our Illustrations.

"OLD MASTERS" ON THE CONTINENT.—XXIII.

From the great collection of paintings in the Royal Gallery at Dresden, the finest in Germany, we give another example this week, being the ninth since our series of reproductions of works by the Old Masters commenced. (The other illustrations from this gallery will be found in our issues of Feb. 8 and 22, March 8 and 29, April 12 and 26, May 31, and June 28 of the current year.) The work now shown is the three-quarter length portrait by Hans Holbein the younger, popularly supposed to be that of Hubert Morette, the Court jeweller to Henry VIII. of England, although it will be seen that Mr. Charles L. Eastlake, in his article on p. 253, concurs with Professor Woermann, the Director of the Royal Gallery at Dresden, in believing it to be more probably the portrait of Sieur de Morette, a French nobleman at the same court. It was formerly supposed to have been painted by Leonardo da Vinci. Whoever may be the subject, as a portrait, from the technical no less than from the pictorial standpoint, the work is admirable.

THE DINING-ROOM IN THE OLD HOUSE OF LORDS, BY JOSEPH NASH.

This excellent drawing by Joseph Nash belongs to Mr. Thomas Stopher, F.S.I., of Winchester, who kindly sent it for reproduction, and it is certainly worthy of a place in our series of direct facsimiles from originals by this master of architectural draughtsmanship. The history of this drawing we are not able to trace, neither do we know at whose instance it was made. The drawings for Brayley and Britton's "Westminster Palace," published in 1836, were executed by R. W. Billings. Sir John Soane, R.A., built in 1823 the Royal Gallery and entrance to the old House of Lords on the site of the old Parliament Chamber, below which was Guy Fawkes' cellar. This ancient building was removed to make room for Soane's work. He may have had to do with the interior of which Nash made this drawing, and it will be remembered that Soane also built the Law Courts, which stood on the western side of Westminster Hall. The old House of Lords was destroyed by fire on the night of October 16, 1834. In 1836, the design of Sir Charles Barry, R.A., assisted by Pugin, was chosen from 97 sets of plans, and the foundation-stone of the new palace was laid on April 27, 1840. Nash's picture has now become historically interesting, and for the crispness of its architectural delineation and power with which the life-like figures are sketched in the drawing is clearly worthy of record. It may be useful to give the dates when other examples in this series of Nash's pictures appeared in the Building News—viz., Jan. 5, Feb. 2, Feb. 23, March 30, May 11, Aug. 3, Sept. 14, Sept. 28, Nov. 23, 1894; Jan. 4, Jan. 25, March 15, April 19, and June 21, 1895. We are still open to receive the loan of any of Joseph Nash's architectural drawings for our series of reproductions of his works, which we are desirous of making as complete as possible.

BISHOPSGATE HOUSE, E.C.

This drawing represents the entrance bay of one of the several large commercial buildings lately carried out in the City of London, where every inch of available space, and the utmost amount of light, necessarily determine the leading characteristics of the street façades. Mr. T. H. Smith has designed and superintended the erection of several such blocks as this, which he has enabled us to illustrate to-day; but we have no precise particulars to print about Bishopsgate House other than these.

UNIVERSITY COLLEGE, ABERYSTWITH: HALL OF RESIDENCE.

The Hall of Residence for lady students of the University College of Aberystwith, of which we herewith give an elevation of the sea-front and plans, is being erected on a fine open site, forming a continuation and a finish to the main parade facing the sea. The site is practically open on three sides, with its main frontage to the sea, the others to the rolling moors and hills, which shelter and inclose the northern end of the great bay of Aberystwith, the opposite end being capped by the buildings of the university, and the remains of the ancient castle. This Hall of Residence, or hotel, is presided over by Miss Carpenter, and is intended to provide accommodation for the ever-increasing number of lady students which flock to Aberystwith. The present block is a portion only of a greater scheme, and provides for the reception of about 150 students, and when completed will house upwards of 200 students. The arrangement includes administrative department, kitchen offices, and so forth, and the great dining-hall, about 70 by 30, and a series of common rooms or drawing-rooms, all on the ground floor; cloak-rooms, drying-rooms, and other departmental offices suited for the completed building; sanitary block, contained in a separate tower, and approached by bridges from every floor; and the accommodation especially intended for the housing of the students' use, which gives them the choice of a combined bedroom and study, with use of the public rooms on one hand, or a separate bedroom and study, or a share in a dormitory and common study. The site is oblong, and the plan consists of three blocks at right angles to the front, and connected along the front by a range of rooms, recessed somewhat from the main line of frontage, and at the rear by the kitchen offices of one story only. Of these, two blocks are now in course of erection, with complete administrative and sanitary departments. The main entrance is in the centre of what will eventually be the central block, with first a recessed porch, then an inner hall with an open staircase to the first floor immediately facing the entrance, and great corridors to the right and left. Corridors about 12ft. wide lead to the great dining-hall, and to a suite of drawing-rooms, which is amply lighted, and form an additional room when required. The other wing will be on similar lines, with probably a library or recreation-room in place of the dining-hall. The passages and staircases throughout are of concrete, and are practically fireproof, and the main staircases, being placed against external walls, are readily accessible from their landings in case of panic. Ventilation has been provided by windows, and by Tobin tubes throughout, and special extracts where required. The windows in almost all cases are coupled, so as to be readily opened or shut, and give an abundant light without the mechanical difficulties of a very large sash window. The arrangements for heating, cooking, and hot-water services have been duly considered, and care has been taken to make the necessary working of the establishment as simple and direct as possible. The kitchen and service rooms are on the ground floor. The sanitary arrangements have received special attention. Each floor has its own service of hot and cold water, and its own access to a semi-detached sanitary block, in connection with a service hoist from the basement. The building is built of fine blue limestone of the locality, with dressings of Grinshill stone from Shropshire. It is being carried out from the designs of Mr. Charles J. Ferguson, of Westminster and Carlisle, in conjunction with Mr. T. E. Morgan, of Aberystwith, and the builder is Mr. David Lloyd, of Aberystwith, who has the whole of the work in hand, except the internal plumber's and sanitary work, for which the tender of Messrs. Braithwaite and Co., of Leeds, was accepted.

A HOUSE AT TEWKESBURY.

This drawing, given in continuation of the series of sketches illustrating the Architectural Association Excursion, is by Mr. Alfred J. Dunn, A.R.I.B.A., who says:—"The existence of the windows to first floor, as shown in sketch, were until a few months ago unsuspected. Mr. Collins, of Tewkesbury, the owner of the property, having decided to restore two windows already in existence (similar to the one in gable, also restored), found it necessary to remove some of the plaster, which at once brought to light the 14th-century work. The whole front was then stripped of its stucco, when it was discovered that, with the exception of the third light from either end, the series was in a splendid state of preservation. Little doubt was felt that originally these two compartments were filled with windows of similar design, whereupon the intention of replacing the two former windows was abandoned, and in lieu of this the openings were made to correspond with the rest, as now seen. No doubt the window-tax would account for the greater part of the windows being obscured. The timber employed is oak, the surface of which is free from paint or tar. The date of execution is considered to be about 1350."

LYCH-GATE, SHANKLIN.

This lych-gate is a memorial to the late squire, Mr. White Popham, subscribed for by the inhabitants of Shanklin, where he was much respected. The side walls are of freestone, the superstructure being of oak, and the roof is covered with Broseley tiles. This part of the work was carried out by Messrs. Cornish and Gaymer, of North Walsham. The eight-day clock, which is contained in the roof, was supplied by Messrs. Gillett and Johnson, of Croydon, the weights being inclosed in the centre-post on each side of the lych-gate. The clock-face, which is of beaten copper, was made by Messrs. Campbell and Smith, and there is a bell under the projecting-barge-board of the other gable. The cost of the lych-gate, exclusive of the clock, was £140. Mr. Arthur C. Blomfield, M.A. (of Messrs. Sir Arthur Blomfield, A.R.A., and Sons), was the architect, and our illustration was reproduced from his pencil drawing, kindly lent us for the purpose.

FRENCH MEDIEVAL AND RENAISSANCE FURNITURE.

The earliest example on the sheet of sketches given on another page is the fine old iron-bound Coffer, belonging to the latter part of the 13th century. Few specimens of woodwork emanating from that period have been preserved, and those that exist are scattered abroad hither and thither, many being greatly mutilated. The chest before us is, however, in a fair state, presenting a somewhat hale old age. To this, its massiveness, and the liberal supply of scrolled ironwork with which it is bound and decorated, no doubt, largely contributed. It seems at one time to have possessed five locks; but, as our sketch shows, several of them are missing, and their places patched with iron or wood. A very different, but also interesting, piece of furniture is the Money Changer's Table of the 16th century. It is shown closed in our sketch; but when in use the top flap was brought over level with the under one, thus doubling the amount of table surface. This flap would be supported by the two shaped brackets, which swing out at right angles. The design of the scroll carving recalls Scandanavian or Celtic work, whilst it is an instance of that delight to enrich and beautify articles of a commonplace character, which is a distinguishing feature of old craftsmanship. Oak and walnut are both used in the construction of this table. The dignified Arm-Chair is made in walnut wood, and belongs to the second half of the 16th century. The space below the seat is inclosed, forming a box, the seat being made to open as a flap between the balusters supporting the arms. The two Oak Panels, carved with crude representations of Evangelistic symbols, are spirited pieces of work of the 15th century. All these objects form part of the "Payre" collection now at the South Kensington Museum.

OBITUARY.

We regret to announce the death of Mr. Henry Clutton, F.R.I.B.A., F.S.I., formerly a well-known architect and surveyor, which occurred at his residence, Hartswood, Reigate, on Saturday last. Mr. Clutton, who was in his eighty-second year, succumbed to what at first seemed a comparatively trivial accident. He grazed the sole of his foot on a crack in a foot-bath, but thought so little of the occurrence that he went out next day for a walk. Inflammation set in, however, from some fragments of enamel piercing the skin, gangrene supervened, and he died after a week's illness. He was one of the sons of the late Mr. John Clutton, surveyor, and after some years' independent practice as an architect, joined his elder brother, Mr. John Clutton, and nephews, in the eminent firm of surveyors at 9, Whitehall-place, S.W. He withdrew from the firm 15 years ago, and retired into private life at Reigate. Mr. Clutton was one of the seniorn members of the Royal Institute of British Architects, having joined that body as an Associate in 1838, becoming a Fellow in 1850; he served for some years on the council. Of the Surveyors' Institution, of which the present Mr. John Clutton was one of the founders, he was an original member, his name being No. 29 on their roll. He was no relation to, though frequently confounded with, his namesake, Mr. Henry Clutton, F.R.I.B.A., of Onslow-gardens, the pupil of Blore, and for a while partner of the late William Burges—that Mr. Henry Clutton, who was five years the junior of the one whose death we now have to record, died in June, 1893.

CHIPS.

The Louvre has obtained a portrait of a young man, painted by Palamedes, dated 1655, and given to the French nation by M. Sedelmeyer. Until now the Louvre possessed no work by this master.

In the case of William Harding, of Market-place, Mitcham-lane, late Thrale-road, Streatham, S.W., carpenter and builder, the discharge from bankruptcy has been suspended for five years, ending July 22, 1900.

In celebration of the fiftieth anniversary of his accession to the Austrian Throne, which falls in December, 1898, the Emperor Francis Joseph intends to present to the city of Vienna the Prater, a notable open space covering 4,228 acres, and containing a central avenue five miles long and with four rows of magnificent chestnuts. It came into possession of the reigning dynasty in 1570.

The parish church of St. Leonard, at Downham, Norfolk, has just received a richly-carved oak chancel screen. It is of 15th-century character, the tracery work in the upper part being almost Flamboyant. There is a wide central doorway, with gates of hammered metal-work, designed, like the screen itself, by Mr. Thomas Garrett, A.R.I.B.A., Percy-road, Shepherd's Bush, W. The sides are panelled and traceried, and the transoms are carved. There are two open bays above these, on the north and south sides respectively of the doorway. The carving upon the main cornice is delicate in treatment, and the whole is surmounted by a pierced cresting. The screen, which is made of English oak, has been carried out in the studios of Messrs. Harry Hems and Sons at Exeter.

There has just been placed in Monzie parish church, Perthshire, by the Rev. Hugh M. Jamieson, a two-light window, in memory of his late wife. The subjects chosen for the windows are the Resurrection and the Ascension. The window is the work of Messrs. James Steele and Co., West George-street, Glasgow.

The sanction of the Local Government Board has been given to a scheme for the drainage of Lydney, prepared for the district council by Mr. Threlfall, C.E. The estimated cost is £5,000.

On Thursday in last week a new Wesleyan chapel at North Luffenham, in the Stamford circuit, was formally opened. Messrs. Hinson Bros., of Stamford, were the contractors for the building.

At the last meeting of the town council of Glasgow it was reported that tenders had been invited for the section of the new aqueduct extending from Loch Chon to Loch Katrine and relative inlet basin, and for the heightening of the inlet basin of the existing aqueduct. This will be the finishing portion in bringing in an additional supply of water, and when it is completed the Water Trust will be able to provide a supply equal to all the needs of the city. It was also decided to proceed with the building of a block of workmen's dwellings in Cumberland-street, East End, being the largest section of workmen's houses with which the Glasgow Improvement Trustees have yet dealt.

Building Intelligence.

Inverness.—The plans of the projected additions to the Inverness Lunatic Asylum having been adopted by the District Lunacy Board, have been submitted, along with the estimates of cost, to the General Board of Lunacy for Scotland. The proposed extensions are estimated to cost little short of £20,000; but it is the intention of the district board that the work shall be carried out in sections. When completed, the extensions will provide accommodation for about 200 patients. At present the patients in the house number 450. The first portion of the extensions to be completed will be an additional male hospital ward at the north-west end, and these will be followed by the construction of a new entrance at the back of the asylum, new shoe-rooms, a new wing for females in the north-east end, and the remodelling of sick wards, &c. The plans were prepared by Messrs. Ross and Macbeth, architects, in conjunction with Dr. Keay, the medical superintendent.

Liverpool.—A new warehouse has just been completed by the Cheshire Lines Committee at their Brunswick Station, Liverpool. The work was designed by and has been carried out under the personal supervision of the company's engineer, Mr. W. G. Scott, C.E. The new warehouse is 600ft. in length by 105ft. in width and 70ft. in height, having three upper floors; also covering three lines of rails and two spacious loading wharves on the Sefton-street level. The frontage is largely built of Ruabon red brick. In the base courses and other portions of the building stone from the Horsforth Quarries, near Leeds, has been extensively used. The three upper floors, like the ground floor, extend the full length and width of the building. The top and second floors, it is proposed to utilise chiefly for the storage of grain. The third floor will be devoted to miscellaneous traffic, while the ground floor will be chiefly used for loading and unloading traffic from the adjoining docks and from town. Care has been taken to occupy as little space as possible with machinery and appliances, and the pillars supporting the floors are a wider distance apart than usual. The structure is of iron and concrete throughout, except the columns, which are of steel, and it is thoroughly incombustible. The whole of the loading, unloading, and hoisting operations will be conducted by hydraulic machinery. Adjoining the building is a new hydraulic pumping station, comprising two compound stationary engines (the patent of Messrs. Tannett, Walker, and Co., of Leeds). There are three large boilers, supplied by the Galloway Company, Ltd., of Manchester. This station contains the largest and most powerful steam-crane power in Liverpool. There is on the wharf a 40-ton steam crane, with a length of traverse of 350ft., and no fewer than 45 hydraulic cranes, 20 sack and bale hoists, and 22 hauling capstans have been laid down to facilitate the work both in the new warehouse and in the yard. Six 20-ton hydraulic traversers have been provided to transfer waggons and trucks without the delay or difficulty caused by shunting from one set of rails to another. Fifteen hatchways have been constructed on each floor, and these are placed above the lines of railway which run through the basement at street level. During the period of the construction of the new warehouse there has been erected a new electric-lighting installation for the whole of the Brunswick Station and yard. There are provided 65 arc lamps, and 350 incandescent lamps. Two 50H.P. engines are employed, and there are six dynamos for incandescent and arc lighting. This work has been executed by the engineer's department, the machinery having been purchased from Messrs. Mather and Platt, Ltd., of Manchester.

Manchester.—The internal appearance of the Manchester Royal Exchange has been transformed, having been redecorated in much brighter tints. Cold greys are replaced by glowing variations on a ground of yellow. The panels under the base of the great central dome, which were formerly dealt with by the general decorator, are now occupied by a series of paintings representing scenes on the Ship Canal. These are by Mr. Edward Noak, of Newton Abbot, who has selected as subjects the Salford Docks, the Partington coal basin, and the Eastham locks, supplemented by a view of the Mersey. Another new feature is the introduction of shields bearing coats of arms of the United Kingdom and the principal cities and towns, all in their proper colours. The work has been done under the supervision of Mr. G. Faulkner Armitage, of Altrincham, from designs by Mr. Murgatroyd, of Manchester, the architect of the Exchange.

Totterdown, Bristol.—Memorial-stones of new school buildings about to be added to Totterdown Free Methodist Church were laid last week. The portion of the work now being proceeded with includes the school and classrooms, consisting of a large room 50ft. by 24ft., with an additional length of 12ft. forming a gallery, the under part of this annexe (intended for an infants' room) being separated from the main room by movable screens. The whole of one side of the school is similarly fitted with glazed movable screens between the piers, and give access to four classrooms adjoining. The façade is in hammer-dressed blue Pennant stone, with dressings of Monk's Park freestone. The whole of the internal joinery will be of pitch-pine. The roof will be of hammer-beam construction, with a boarded ceiling, polygonal in shape. The floor will be of wood blocks on concrete. The additions to the chapel embrace the substitution of a large traceried window for the present window and door in Oxford-street; a tower with a spire 70ft. high; a porch with pinnacled octagonal piers and truncated roof in Bush-street; and new boundary-walls, gates, railings, and lamps. In addition to these, the chapel is to be extended about 12ft., and minister's room provided. The whole of the stonework will be renewed or cleaned, as the case may be, and the windows fitted with leaded lights. The gallery will be altered, and fitted with a new iron front. A new choir and organ gallery and rostrum will be fitted at the new end. The whole of the chapel will be reseated with pitch-pine seats, and the gasfittings and ventilation renewed. with the addition also of a new heating apparatus. Other works and decorations will also be carried out. The architect is Mr. William Paul, Wells-road, Bristol.

The ceremony of turning on the new water supply for Lostwithiel will be performed by Lady Robartes on Thursday, August 23.

An appeal is being made for £2,000 for the restoration and repair of St. Leonard's Church, Leicester, built in 1876, and one of the poorest parishes in the town. The works will be carried out from plans by Mr. Goddard, of Leicester.

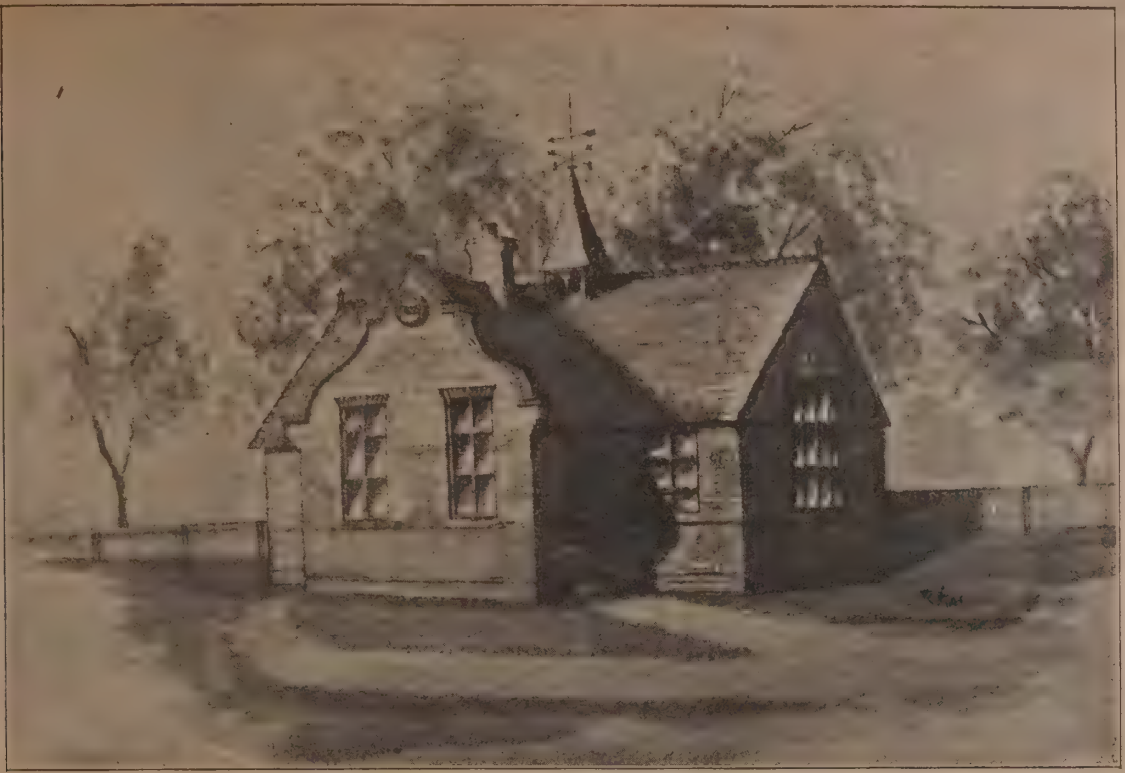
Lord Esher, who completed his eightieth year on Tuesday in last week, has lately had erected in the churchyard of Esher, in Surrey, his own and wife's effigies in marble, though both are at present in the enjoyment of excellent health. They are represented as lying under a canopy with their hands clasped and their eyes closed as if in death. The work is by Mr. J. F. Williamson, of Esher.

The judgment of the Chancellor of St. David's on the question of the rebuilding of Swansea parish church was delivered at Carmarthen on Saturday. It was stated that in accordance with a report and plans prepared by Sir Arthur W. Blomfield and Sons, the whole structure will be rebuilt, excepting the Herbert Chapel, which is to be restored and thrown open to the new church. The work will be carried out in two stages, at an estimated outlay of £24,000. The judgment stated that the faculty will be granted, and leave was given to commence the work after fourteen days from the delivery of the judgment.

Major-General C. Phipps Carey, R.E., held an inquiry at the Guildhall, Windsor, on Friday, with reference to an application which had been made by the Windsor Town Council to the Local Government Board for authority to borrow £850, to carry out some Thames-side improvements in the vicinity of the ferry. The alterations will include the construction of 679ft. of camp shedding, the taking in of portions of the Thames bed between River-street and a boathouse upon the Berkshire shore, and the making of a promenade thereon. There was no opposition to the application.

The Duke of Fife has commissioned Mr. Marshall Mackenzie, of Aberdeen, to prepare plans for a new house in Mar Forest, to take the place of Mar Lodge, and building operations will be commenced in October. The new house is to be on a much larger scale than the one recently burnt down.

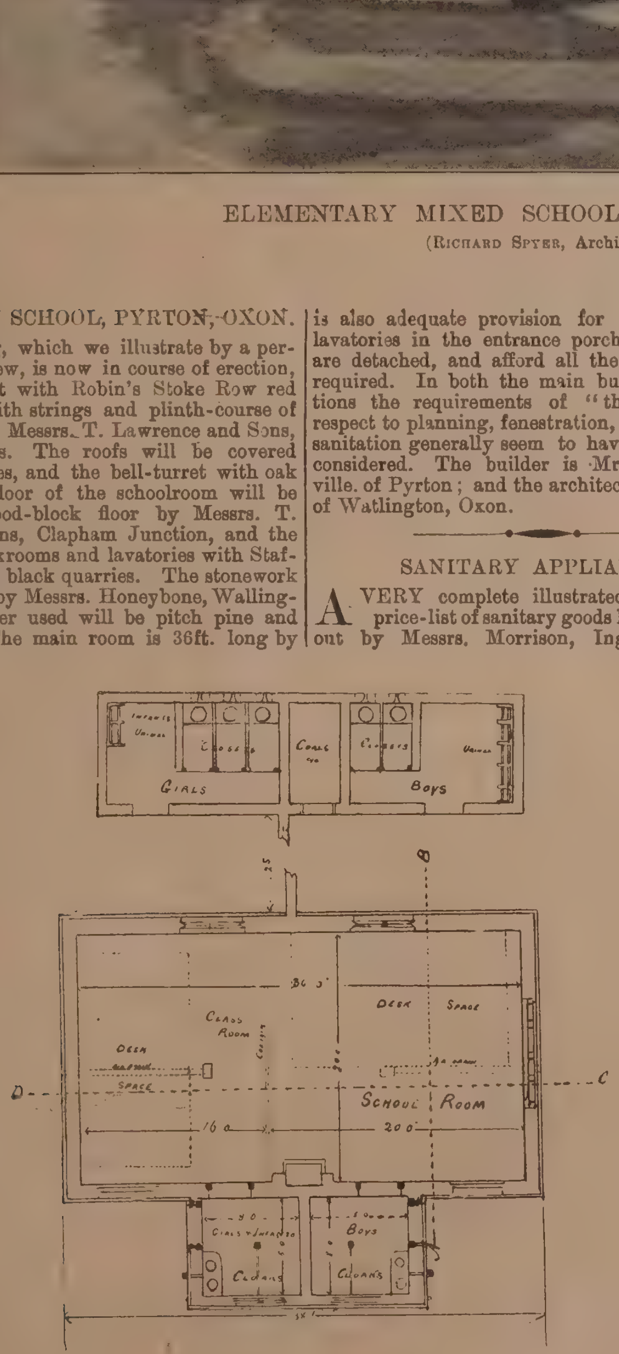
A special meeting of the St. George's vestry, Southwark, was held on Friday, for the purpose of considering the offer of a building for a free library made by Mr. J. Passmore Edwards, subject to a site being provided. Mr. Haynes moved that the offer should be accepted, subject to the decision of the parishioners to adopt the provisions of the Free Libraries Act. The resolution was adopted unanimously. The overseers were requested to take a poll of the inhabitants, and a committee was appointed to take such further steps as may be desirable.



ELEMENTARY MIXED SCHOOL, PYRTON, OXON.
(Richard Spyer, Architect.)

ELEMENTARY SCHOOL, PYRTON, OXON.

THIS building, which we illustrate by a perspective view, is now in course of erection, and will be built with Robin's Stoke Row red pressed bricks, with strings and plinth-course of red rubbers from Messrs. T. Lawrence and Sons, Bracknell, Berks. The roofs will be covered with Broseley tiles, and the bell-turret with oak shingles. The floor of the schoolroom will be laid with a wood-block floor by Messrs. T. Gregory and Sons, Clapham Junction, and the floors of the cloakrooms and lavatories with Staffordshire red and black quarries. The stonework will be supplied by Messrs. Honeybone, Wallingford. The timber used will be pitch pine and English oak. The main room is 36ft. long by 20ft. wide, with provision for subdivision. It will accommodate about 70 children, and is so constructed as to be also, at night-time, conveniently used as a parish meeting room. There is also adequate provision for cloakrooms and lavatories in the entrance porch. The latrines are detached, and afford all the accommodation required. In both the main building and additions the requirements of "the Code" with respect to planning, fenestration, ventilation, and sanitation generally seem to have been carefully considered. The builder is Mr. George Glanville, of Pyrton; and the architect, Mr. R. Spyer, of Watlington, Oxon.



* * *

SANITARY APPLIANCES.

A VERY complete illustrated catalogue and price-list of sanitary goods has been brought out by Messrs. Morrison, Ingram, and Co., Hygeia Works, Manchester, manufacturers of improved lavatories, baths, closets, sinks, &c. The illustrations are chromo-lithos, in a style which leaves little to be desired. The patent "D" lavatory, in which the arrangements of taps and inlet and the shape of the bowl are special points, is a great improvement on the usual fitting. A great variety of designs is shown. The patent steamless and noiseless "D" lavatories are noteworthy. The improved shape of the bowl affords every facility to the user, being wider in front. No loose fittings are inside, but each lavatory has hot and cold taps, quick waste, 1½in. central tube overflow, and 1½in. overflow. These are made in various designs in the finest ivory or white porcelain, and are either angular or square on plan, to suit the corner or side of room. Some are fitted with a swivel shampoo and eye-spray. Several designs are shown of decorated lavatories of very beautiful patterns. When we say that 57 pages are devoted to illustrations of lavatories of every class and description intended for mansions, hotels, clubs, schools, asylums, railway carriages, &c., some idea may be formed of the variety of purpose and of design represented. Many lavatory ranges of slate, cast iron, and fire-clay are shown, suitable for schools, &c. The next section is devoted to baths: cast iron for wood casings, Roman baths, fire-clay enamelled, and other kinds are illustrated. The "patented combination" in which lavatory and bath are combined seems a very economical arrangement where space is limited. Spray, shower, and reclining baths, needle, and other forms are given. Water-closets, &c., of several excellent forms, "wash out" and "wash down," form a useful section. Plumbers' brasswork, bath boilers, flushing tanks, sinks, slop-hoppers, &c., are fully illustrated and priced. Architects specifying these and other sanitary fittings will find Messrs. Morrison, Ingram, and Co.'s catalogue useful, as they can select their own pattern from its pages.

* * *

The Public Works Loan Commissioners during the financial year 1894-95 made 876 advances for sums amounting together to £1,612,143, as against 786 advances for £1,582,783 in the previous year, showing an increase of 90 in the number of advances, and of £29,380 in the amount advanced.

The rector and churchwardens of All Saints' Church, Southampton, are appealing for £1,000 to enable them to effect long-needed repairs and improvements to this edifice, the centenary of which is about to be celebrated. It is proposed to restore the cement work on the exterior, to replace the present windows with cathedral glass, and to effect repairs to the roof, the east end, the East-street entrance, and the tower.

AN AMERICAN DOUBLE COTTAGE.

We give on page 264 two interior sketches, together with plan and end elevation, of a simple, but interesting, arrangement for a double cottage. This plan, although it has its objections, is no doubt economical in various ways, and gives importance to both residences, the whole being under one roof, and from the outside presenting the appearance of one large house.

The window and fireplace show the treatment of the dining-room interiors. The window-sill is about 4ft. from the floor, and is wide enough to form a shelf for plants, books, or ornaments.

The height of rooms is 8ft. 6in. from floor to underside of beams. The wood used in the finish to be either Canadian ash or American oak, stained a greenish colour—or a "broken" colour of green and brown in the figure of the wood. The frieze is of coarse canvas, painted in colours. The firedogs and fireback are cast iron adapted from old English designs. Mr. R. Brown, jun., of Boston, Mass., is the architect, and we are indebted to the *American Architect* for the illustrations.

CHIPS.

The Supplementary Civil Service Estimates issued this week include £30,421 for the British Museum, the bulk of it being required for the purchase of the Malcolm collection of drawings, and the correspondence and papers of Lord Nelson; and £5,000 for the National Gallery.

Receiving orders have been made in the case of Henry Phillips, of Exeter and Taunton, builder; and in that of William Rowe, Fore-street, Marazion, Cornwall, builder.

At the London County Sessions, on Saturday, John Armstrong, a carman in the service of Messrs. Heather, Bailey, and Co., builders, Gravel-lane, was convicted of stealing a load of sand, the property of his employers, and William Henry Horswill, builder, Lant-street, S.E , was convicted of having unlawfully received the stolen property. Armstrong was sentenced to three and Horswill to six months' hard labour.

At a meeting held a few days back the committee of the Bristol School of Science and Art had under consideration the appointment of head-master. From among 26 candidates, they selected the Rev. E. J. Bush, a late master at the National Art Training School, South Kensington. Mr. Bush held one gold, seven silver, and eleven bronze medals, and won in 1893 two scholarships—those of the British Institute for Etching and the Travelling one of the National Art Training School.

There has just been sold by private treaty the freehold site of 170 and 172, Lavender-hill, Wandsworth, having a frontage of 96ft, and an area of 1¾ acres, for £5,000.

It is proposed to restore, at a cost of £600, the old cathedral church of Lismore, Argyleshire, built in 1220-40, and to that end a three days' bazaar has been organised in Oban to aid the fund. The bazaar was opened on Tuesday by Sir Donald Smith, of Glencoe.

The British Consul at Piræus has reported on the new trade in native magnesium carbonate and in fire-bricks manufactured therefrom which has sprung into existence in Greece. There are large deposits of nearly pure magnesium carbonate in Eubœa, near Corinth, and elsewhere in Greece. It is quarried from lodes, and exported either in the crude state or calcined, and has been used for extracting the resin from wood pulp, and for weighting calicoes. Now, however, it is being ground, and made into firebricks, which are capable of resisting a temperature of 2,150° (whether Fahrenheit or Centigrade is not stated) against the 1,800° which the ordinary firebrick will stand.

The Iron and Steel Institute commenced its autumnal sittings at Birmingham on Tuesday, Sir D. Dale presiding. In a paper on the iron industries of South Staffordshire, read by Mr. Daniel Jones, the statistics showed that for some years the production had steadily decreased; but the writer anticipated that the business of the district would revive. A paper by M. Emile Bonehill, of Belgium, upon a new method of puddling, for which a saving of 11s. 9d. per ton was claimed, excited much interest. At Wednesday's meeting papers were read by Professor W. N. Hartley, F.R.S., on "The Thermo-Chemistry of the Bessemer Process"; by Mr. H. M. Howe, of Boston, "The Hardening of Steel"; by Mr. R. A. Hadfield, "The Production of Iron by a New Process"; and by Mr. E. H. Saniter, "A New Method of Analysing Chrome Ore and Ferro-chromium." In the afternoon an excursion was made to Worcester by the members, and in the evening a reception and entertainment were given by the local reception committee in the Botanical Gardens, Edgbaston.

COMPETITIONS.

Chester Baths.—At the last meeting of the city council of Chester the report and award of Mr. Frank T. Baggallay, F.R.I.B.A., of Conduit-street, W., the assessor in the public baths competition, was received. Mr. Baggallay stated that, after a full and anxious consideration of the 27 competitive plans submitted, he advised the selection of the design bearing the motto "Plan" as the one which best combined simple and suitable arragements and an adequate mastery of the rather technical details of this class of building, with a due regard for the special necessity for a sightly building, and a similar regard for the important consideration that no part shall be nearer to the City Walls than 40ft. Among the good features of this design the concentration of the entrances and offices and the excellent arrangement for overlooking the corridor to the second-class baths throughout its length, were especially to be commended. So also was the arrangement of the men's slipper and vapour baths, enabling one attendant to manage both classes. The provision of an entrance from the women's baths to one of the swimming baths was also a good feature of the plan. The extra exits from the large bath and the public staircases from the gallery were well placed, and of sufficient width. The gangways and dressing cubicles to the swimming-bath, the slipper-bath cubicles, and the corridors were of adequate size, and the w.c.'s and urinals were well placed. The diving-board in the large bath should be at the deep end, but this was obviously an oversight; the author noted the proper position in his report. The laundry and boiler-house were well planned, though the space in front of the boilers was too cramped. Externally, the grouping of the building as seen from the City Walls, and the masking of the usually unsightly wall of the large bath were well managed. The extent of the space left available for ornamental garden between the building and the City Walls was decidedly a good feature, and the assessor did not see why this should not be somewhat increased by reducing the space on the east side. The method of approach from the City Walls was admirably conceived. The "Rosher" system of heating the water in the swimming-baths, the one adopted in this design, was a comparatively new one, and the assessor had no personal experience of it, but he was informed and believed that it had been used with most satisfactory results, and that it maintained both the temperature and the freshness of the water without waste. The steam and hot-water pipes and the drainage were very well arranged. The constructive details and the materials shown and described were satisfactory. There was no unnecessary extravagance or excess of ornament in the design, and the estimate for the engineering work ought to be sufficient. After a careful comparison and calculation of cubical contents of several of the designs, he did not think that any design which he could recommend as suitable for adoption would cost materially less. Before concluding he ought to point out that the concrete floor over the subway was not sufficient support for the thick north wall and the chimney-breasts of the second class waiting-room, and that this fireplace has no chimney, and presumably no flue. But for these incomprehensible oversights he should have even less hesitation in recommending the acceptance of this plan. Fortunately they could be remedied without difficulty or injury to the design. The boating and baths committee having considered the report, ordered that it be approved, and that the author of the plan be awarded the premium of £50. The author was discovered, on the opening of the identification letters, to be Mr. Harold T. Burgess, architect, 33, Palliser-road, Kensington, W. At a subsequent meeting the committee ordered that the foregoing proceedings be reported to the council, and that it be recommended to the council that the committee be now authorised to obtain tenders. Also that the committee be authorised to pay Mr. Burgess the premium of £50, and Mr. Baggallay the fee of £52 10s. A discussion followed, in which Alderman Gilbert suggested that an alternative site might be considered before the work was actually commenced—namely, that near the steps leading down to the Suspension Bridge, under the Hermitage. That site would obviate the erection of a large chimney near to the cathedral; they would have there an abundance of water, without cost. The Mayor said the suggestion should have the best consideration of the committee; but that should not delay the advertisements for tenders. The meeting unanimously decided to advertise for tenders for the erection of the baths.

Guernsey.—The St. Piesse du Bas (Guernsey) Parochial Committee have selected the designs sent in by Mr. Frank Whitmore, architect, Chelmsford, for new schools, and the same have been approved by the States Committee.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

British Archæological Association.—The members of this association have held their fifty-second annual congress this year in North Staffordshire, the scene of their meetings being the Town Hall, Stoke-on-Trent. The proceedings commenced on Monday week with a reception by the mayor and corporation of the borough. The mayor (Alderman J. Birks) extended a hearty welcome to the members of the association. Mr. W. S. Brough, on behalf of the North Staffordshire Field Naturalists' Club and Archæological Society, also offered a cordial welcome to the visitors. Mr. Thomas Blashill, of London, acknowledged the reception. The members afterwards paid a visit to the churchyard of the parish church, and the site of the ancient church was examined. Subsequently, under the leadership of Mr. W. D. Spanton and Mr. Charles Lynam, F.R.I.B.A., they visited Trentham, Bury Bank, and other places of antiquarian interest. In the evening the association were the guests of the North Staffordshire Naturalists' Field Club and Archæological Society, when Mr. W. S. Brough delivered an inaugural address upon the history and antiquities of North Staffordshire, and Mr. Scrivener illustrated, by aid of lantern slides, many of the places to be visited by the congress during the week. On the Tuesday the members made an excursion viâ Abbey Hulton and Milton to Leek. The foundations of the ancient Cistercian Abbey at Abbey Hulton, unearthed some ten years ago by the late Rev. Walter Sneyd, of Keele Hall, the owner, were first visited; Mr. Charles Lynam giving an interesting sketch of the history of the abbey and explaining its outlines and general arrangements. At Milton the party took train to Leek, where, under the leadership of Mr. W. S. Brough, they visited the parish church, which is full of archæological interest. The Cistercian Abbey of Dieu-la-Cress, Rushton Church, the "Bride Stones," and Biddulph Old Hall were likewise inspected. In the evening a meeting was held at the Town-hall, Stoke, when papers on Staffordshire Folklore, St. Chad's, Lichfield, and the Town and Priory of Stone were read. Lichfield Cathedral was seen on the Wednesday.

* * *

Last week's transactions at Tokenhouse-yard were very quiet. The aggregate realisation amounted to £55,423, for more than half of which the sale of the South London Music Hall was responsible. This week's chronicle is even more meagre. There have been only about half-a-dozen sales altogether, and the tide of business has been at its lowest ebb.

The urban district council of Tonbridge have under consideration a report and scheme prepared by Messrs. Hennell and Gould, of Westminster, for a river relief channel, 40ft. in width, to be constructed from Bailey's Weir to Child's Lock, for the prevention of floods. The estimated expense is £6,200.

Col. J. Ord Hasted, R.E., attended at Lincoln on Tuesday to hold an inquiry into an application made by the Branston Rural District Council for sanction to borrow £850 for purposes of sewerage and sewage disposal in the parish of Boultham, the sum sought to be borrowed being entirely for extras over and above the contract price, for which a loan had previously been raised. It was explained that the contractor claimed £350 extras on the ground that in the bill of quantities no reference was made to pumping in the excavations or for an ejector tank. Another extra was £133 9s. 4d. for excavations for a rising main, and £74 5s. 2d. in respect of a miscalculation in the ejector tank. Other small items brought up the extras to about £750. The surveyor to the council disputed the extras, asserting that only £142 10s. 2d. was due to the contractor, and that that was subject to a deduction of £78 penalties for non-completion of the work in the prescribed time. The council appointed Mr. Walker, of Nottingham, as the virtual arbitrator, and he certified that £906 1s. 3d. was due to the contractor. From this the council deducted £33 10s. allowed for interest, and the contractor had obtained judgment for the balance, £872 11s. 3d., and action with regard to the interest was pending.

Engineering Notes.

Lancashire, Derbyshire, and East Coast Railway.—At the half-yearly meeting of this company, Mr. R. Elliott Cooper, the engineer, described the progress of the works, remarking that those from Chesterfield to Warsop, with the several colliery branches, were rapidly drawing to a completion. The heavy cutting about two miles from Chesterfield and the Bolsover tunnel would be completed in March next year. On the second contract the railway was almost completed, including the colliery connections as far as Barlborough, and beyond that point to the junction with the Manchester, Sheffield, and Lincolnshire Railway at Beighton very good progress continued to be made. On the third contract, which commenced at a point twelve miles east of Chesterfield and terminated at the Great Northern Railway at Tuxford, the whole of the double line would be completed by the end of November. Here there were extensive sidings and a coal depot. Some delay had taken place in the section between Tuxford and Lincoln in awaiting the passage of the company's Bill, which enabled them to construct the viaduct over the river Trent at a lower level than originally intended. The work would now proceed without further interruption. The chairman, Mr. Bainbridge, M.P., said that the whole of the line would be completed and open for traffic between Chesterfield and Lincoln in June of next year, and the part from Beighton to the connection near Barlborough towards the end of 1896.

CHIPS.

The Right Hon. A. Akers-Douglas, the First Commissioner of Works, has given instructions for an examination to be made of the Duke of York's Column in Waterloo-place. It is stated that portions of the stonework need renovation.

The latest addition to the stained glass of Carlisle Cathedral has been placed in the east window of the north aisle, in memory of General C J. Mounsey Grant. It is of two lights, in the Decorated style, representing three military figures — namely, St. Michael and St. Longinus, and, in the tracery, St. George. At the base is shown St. Michael again with his angels, all with swords and shields.

The directors of the Kettering Waterworks Co., for the purpose of augmenting the quantity of water stored in Kettering, have purchased land and are proceeding with the construction of an additional service reservoir at Clover Hill, to contain 300,000 gallons of water.

The first mountain electric railway constructed in the United Kingdom, extending four and three-quarter miles, with a continuous gradient of 1 in 12, from Laxey to the summit of Snaefell, over 2,000ft. above the sea level, was inspected on Friday on behalf of the Manx Government by Colonel Rich, of the Board of Trade, and Major Cardew, of the Home Office, and having been passed by these officials the line was formally opened on Tuesday. Messrs. McKerrow and Fell were the engineers, and Messrs. Mather and Platt, of Manchester, supplied the electrical plant.

The chairman of the Hornsey District Council has obtained from the Ecclesiastical Commissioners the definite refusal of Churchwood Bottom Wood, Highgate, until December 31, 1896, at the price of £25,000. Time will thus be afforded for communication and conference with other local authorities.

A survey is being made by Mr. G. Wolfe Brennan, C.E., of Oban, of a projected extension of the West Highland Railway system to Lochfyne, with a terminus and railway pier at Cuil. At this place there is deep water close to the shore, and there is also good and safe anchorage. Cuil is situated near the head of Lochfyne, on the west side, about seven miles from Inveraray by road and four by water. Close by are the ruins of an ancient castle. The line, as proposed, will join the West Highland line between Ardluie and Tarbert, on the west margin of Loch Lomond. The length of the line will be about twenty miles. No serious engineering difficulties are anticipated.

A fund is being raised for the preservation and restoration of the temples of Karnak, the most impressive and historically the most important monuments of the whole Nile Valley. They have been in imminent danger of destruction from the action of the river water, but the danger is being faced, and the work of preservation is in a fair way to be successfully carried out. Some £900 is still needed, however, to place the necessary pumping and draining works on a satisfctory footing. When this has once been done, the Egyptian Government agrees to provide for the annual working expenses.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—S. N. and Co.—R. Emerson.—C. J. W.—Rover.—B. R. and Co.—J. M.—Competitor.

Correspondence.

DURHAM COUNTY COUNCIL COMPETITION.

To the Editor of the Building News.

Sir,—Though, fortunately, I was not a competitor, I read with satisfaction "in your last week's issue" the communication of Messrs. Philip, Tree, and Price anent the above, and earnestly hope that every one of the gentlemen more immediately interested in this affair will support the action contemplated by the above-named gentlemen.

Surely, Sir, it is time that something should now be done to make an end of this sort of work. I have little faith in the honour of any body of men who can act as the Durham County Council have acted in this matter, and am fully persuaded that unless some more decided action is taken, not only will Messrs. Cooksey and Cox lose the work, which they have honourably won, but there will be added another to the long black list of *bogus* competitions.

Why not, therefore (having first afforded the D.C.C. an opportunity of doing right in this matter), make a test case of this, and bring the matter before one of Her Majesty's judges? I am well aware of the responsibility involved in such a proceeding, and know also that it cannot be done without money; but being one of those cases which very materially affects the whole of the profession, there ought not to be any difficulty in raising the necessary funds. The cost of bringing on the action would not be great; whilst, even supposing it should happen to be decided against us as a profession, the influence created would have, "more or less," a lasting and good effect. But from a personal experience of a very similar kind, I am inclined to think the case to be what lawyers would term "a good one."

Is the Royal Institute powerless to do anything in this matter? Nowadays we have associations and unions of all kinds, and in all trades and professions (excepting architecture), fighting for their rights and protecting their own interests. Why should not we? However, I would suggest that a committee be formed, subscriptions invited, and the case fought out thoroughly, and let us see where we stand. Had time permitted, I should have liked to put the matter more clearly, but am in great haste.—I am, &c.,

Newcastleton.

Sir,—There are two sides to every question, and while the wrongs, fancied or otherwise, of the unsuccessful competitors, and the firm who were so fortunate—though apparently they think differently—as to gain the first premium, are being freely ventilated, perhaps an outsider who was not tempted into this particular competitive whirlpool may be allowed to make a few remarks.

While deploring as deeply as anyone else, who cannot get what he wants, the undoubted unfairness and favouritism that obtains in so many public competitions, I fail to see the sense of so much indignation in this case, or the plaintively-worded protest whose earnest prayers are intended to save our down-trodden profession from eternal disgrace, and to force a presumably sane committee to accept a design they do not want.

What if an assessor, however capable, has selected a particular design? The committee in whose employ he is acting are surely not compelled by any law of necessity or etiquette—certainly not of precedence—to accept it.

They acknowledge his choice by awarding the first premium to the plans he has chosen; but, preferring another design to grace their city, are only within their rights when they elect to employ its authors.

It should also be remembered that an assessor, being mortal, is as liable to make mistakes as anyone else who has to work for his living.—I am, &c., One of the Profession.

Sir,—Could not the Durham County Council reply with some truth, "Physicians, heal yourselves"? Constantly great complaints are made in reference to the way in which competitions are conducted; committees are roundly abused, and no one is moral but those in the architectural profession. In the above matter I notice that Messrs. Tree and Price are taking a prominent part, signing themselves as architects to the King's Lynn Municipal Building, which they won in competition in such a way as to quite disgust me with competitions. In this competition a great deal was asked for at a comparatively small amount to be expended. This condition I, in common with probably most of the competitors, and certainly with Mr. Seger, who was placed second, kept carefully in view. Messrs. Tree and Price sent in a design elaborate and ornate in the extreme, and against which simple designs had no chance unless the condition of cost was adhered to, and I have ever since felt, rightly or wrongly, that a gross injustice was perpetrated by these two joint competitors. Reform in these matters requires to begin from within. If the Durham County Council, in dealing with Messrs. Tree and Price, would ask them how they reconcile their expensive elevation for King's Lynn building with the condition as to cost, I think they would prefer to let "well alone."—I am, &c.,

One Disgusted with Competitions through
His Experiences at King's Lynn.

BLUE LIAS LIME—A CAUTION.

Sir,—We append copies of a correspondence we have had with the London Chamber of Commerce on this matter, together with circular referred to.

[Copy.]

London Chamber of Commerce,
Botolph House, Eastcheap, London, E.C.,
July 18, 1895.
Messrs. Greaves, Bull, and Lakin, Paddington.

BLUE LIAS LIME.

Gentlemen,—I am in receipt of your circular dated yesterday. I presume that although you do not allude to the fact in your circular, the practices which you describe would be a distinct offence under the Merchandise Marks Act, procedure under which is facilitated—firstly, by the fact that expenses thereunder before a magistrate are inconsiderable; and, secondly, from the fact that the onus of proof lies upon the defendant. In the event of the practice continuing, you will have rendered a valuable service by the issue of your circular, inasmuch as no person who has received that circular will henceforward be able to plead ignorance. From this point of view, perhaps, it might have been better had the Merchandise Marks Act been alluded to in your circular, and I am writing you in case you should think it desirable later on to issue a second edition thereof, in which you might make this allusion, and so strengthen possible future proceedings, either by individuals or collectively, on behalf of the trade in this matter.—Yours faithfully,

(Signed) Kenric B. Murray, Secretary.

P.S.—I shall be obliged if you will forward me two additional copies of your circular.—K. B. M.

Kenric B. Murray, Esq., secretary,
London Chamber of Commerce.

BLUE LIAS LIME.

Dear Sir,—We inclose additional copies of our circular which has been sent to all architects and engineers in and around London.

We are obliged for your thoughtful suggestion with reference to the Merchandise Marks Act, which we will adopt should we issue a further edition.

Although clause 2, subsection (*d*), would, without doubt, bring the practice referred to within its provisions, the writer is of opinion that, under the pretence of custom the Act is evaded to a very large extent. In support of this opinion he would refer to the official work (Vol. III. 1893) published on the Geological Survey, where, under the head of "Economic Geology," reference is made to this very point. Further, in a correspondence which appeared in the *Contract Journal* in November or December last, it was openly advanced by interested parties that "a custom had grown up of describing all hydraulic lime as blue lias," also that "blue lias possessed a double meaning: (1) lime made from a blue lias stone, (2) lime possessing certain hydraulic properties."

Under such circumstances it is not surprising to find the deception practised on builders and architects and their clients, to which we allude in our warning.—Yours truly,

For Greaves, Bull, and Lakin.
(Signed) H. J. Harding.

BLUE LIAS AND MERCHANDISE MARKS ACT.

Messrs. Greaves, Bull, and Lakin, Paddington.

Gentlemen,—I am in receipt of your favour of the 20th, with enclosures, for which I am obliged. Doubtless if a custom of the trade can be shown to exist, it will make a difference; but, as I have said previously, the onus of proof would here again, I believe, be upon the defendant.—Yours faithfully,

(Signed) Kenric B. Murray, Secretary.
(per G. G. C.)

MERCHANDISE MARKS ACTS.

Dear Sir,—Referring to previous correspondence, I shall be obliged if you will kindly advise me, at your early convenience, for the information of the special committee appointed by the Chamber to consider the above Acts, whether you desire to make any further representations in regard to the working of these Acts.—Yours faithfully,

(Signed) Kenric B. Murray, Secretary.

[CIRCULAR.]

We beg respectfully to call the attention of all interested in good building and engineering work to the following most important facts, the knowledge of which may be the means of saving disappointment and loss.

Since it has become generally recognised by architects and engineers that Blue Lias lime is the lime best adapted for reliable mortar and concrete, the increased demand has led to a practice amongst some merchants and lime-burners of selling as Blue Lias lime (and in bags marked as such) material which is not Blue Lias lime at all.

It has come to our knowledge that a large and increasing quantity of lime is daily arriving in London and neighbourhood, and being sold as Blue Lias lime, which comes from districts where the Blue Lias formation does not exist, and also that a quantity of material, consisting largely of refuse from Portland cement works, is now sold as Blue Lias lime or hydraulic lime.

This being the case, it becomes a matter of the utmost importance to engineers and architects who are responsible for work to see that no deception is practised in the supply of a material on which its stability mainly depends.

In large and important public works, such, for instance, as the Tower Bridge and Blackwall Tunnel, the greatest care is exercised to obtain the best Blue Lias lime; but in a vast number of smaller works, which, though they may not be public, are of equal importance to those who provide the money for carrying them out, anything is accepted as Blue Lias lime which comes so invoiced and in sacks so marked, and it is only after the work has progressed some way, or possibly been completed, that it is found that there is the most serious defect which can possibly occur—a defect in the mortar and concrete. Complaint is made to the merchant, who, in his turn, complains to the manufacturers, and it is only when the material is traced to its starting point that it is discovered that it is not Blue Lias lime at all, but lime of some other description altogether, or very possibly some refuse containing an admixture of lime.

Our object in bringing the matter before you is not to advertise Greaves's Blue Lias lime, but in some degree to check a practice which, though injurious to us as manufacturers of genuine Blue Lias lime, is far more injurious to those who unwittingly allow themselves to be misled in the manner we describe.

Engineers, architects, builders, and contractors should not be satisfied when they receive material invoiced as Blue Lias lime that it is what it professes to be, but should satisfy themselves that it is supplied by one or other of the well-known manufacturers of genuine Blue Lias lime.

We have looked very carefully into this matter, and have satisfied ourselves that the practice referred to exists to an extent little suspected by those whose business does not bring them into almost daily contact with cases of the kind, as ours does.—We are, &c.,

Greaves, Bull, and Lakin.
13, South Wharf, Paddington, W.

ASSISTANT SURVEYORS, WAR OFFICE.

Sir,—About the end of 1893 the advantages and disadvantages connected with the above were freely discussed in your columns. I have since heard that travelling expenses are now allowed surveyors in changing stations, and that, on the whole, the service is made much more tolerable. If you could kindly find space for this letter, perhaps someone will let us have the truths? It would be especially interesting at this time, as another examination is to be announced very shortly.—I am, &c., Prospect.

CHIPS.

Good progress is being made with the provision of sewage work for Rawdon at Cragg-wood. The works are being carried out for the district council from plans by Mr. W. H. Radford, of Nottingham.

On Saturday the first school erected by the Lancaster School Board was opened by the Mayor of Lancaster, who is also chairman of the school board. The present building is only for 300 infants, though the full plans adopted provide for a mixed school to accommodate 1,000 children. The site cost £1,744, and, with the buildings, £2,483, the total cost per head being £8 6s.

At the West London Police-court, on Monday, Mr. Lane, the presiding magistrate, refused to make an order compelling the London School Board to erect a wire fence above a playground to prevent damage by stones thrown by the children. The School Board, it appeared, declined to provide netting on the ground that, if they acceded to one demand, they would have to fence in all their playgrounds in like manner.

A field containing an acre of land has just been added to the Arboretum at Lincoln. The field had a considerable fall to the south, and a great deal of excavating and filling-in was necessary. Mr. H. E Milner, of Westminster, was engaged to furnish designs, and these have been carried out under the superintendence of the city surveyor and a foreman of Mr. Milner's, at a cost of about £1,000.

A range of brick and iron warehouses which are being erected at the docks, Manchester, by the Manchester Ship Canal Warehousing Company for the Ship Canal Company are being proceeded with by the contractors, and considerable progress has been made, notwithstanding that unlooked-for delays have arisen in connection with the foundations. It is hoped that some, at least, of the 19 warehouses will be ready in time to accommodate part of the coming season's cotton crop.

Mr. Vivian, from the General Builders' Co-operative Society, addressed a meeting of builders' workmen at the Fore-street Temperance Hall, Exeter, on Friday evening. Mr. Henry Loman presided. The objects of the society were to organize the workers in the building industry on a co-operative basis, to undertake public and private contracts, and to carry on the trade of general builders and contractors. The capital is raised by shares of £1 each, payable 6d. per week per share. It was decided to form a branch society in Exeter.

Extensive alterations and additions are being carried out at the gas works at St. Alban's. They have been designed by the company's engineer, Mr. A. Phillips, M.I.C.E., and are being carried out in accordance with the plans and specifications prepared by him, Mr. Charles Bedford acting as clerk of works. The work is let in several contracts; the buildings to Messrs. J. and W. Savage, St. Alban's; the retort settings to Messrs. Giltrow Bros.. of Dudley; the condensers to Messrs. C. and W. Walker, of Donnington; the engine and exhausters to Messrs. B. Donkin and Co., London. The boilers are supplied by Galloway, Limited, of Manchester; and the ironwork by Messrs. Westwood and Wright, of Brierly Hill.

Intercommunication.

QUESTIONS.

[11401.]—**Warehouse Floors.**—In designing a warehouse floor, what load should the beams be calculated for per square foot?—Zero.

[11402.]—**Mortar.**—Will a practical reader tell me what quantity of mortar is required for a rod of brickwork?—Beginner.

REPLIES.

[11395.]—**Concrete Arching.**—The experimental information "Sigma" requires is not accessible, as far as I know. There are, it is true, results recorded in treatises; but they are not reliable, owing to the difference of composition of the concrete, its age, and the exact conditions of loading. Mr. G. Sutcliffe's work on "Concrete" gives Mr. Colson's tests. Mr. Thos. Potter's book on concrete gives a few experiments in connection with slabs and landings made of concrete.—G. H. G.

[11395.]—**Concrete Arching.**—Comparatively few experiments on concrete arches have been recorded, and in many of those that have been recorded, one or more of the particulars desired by "Sigma" are not given. On account of the varying qualities of concrete, the subject is fraught with considerable difficulty, and a large number of careful and expensive tests would be required before an accurate formula could be calculated. An approximate method of ascertaining the strength of arched concrete floors is given in Sutcliffe's "Concrete: its Nature and Uses" (published by Crosby Lockwood and Son). It is based on tests made by Mr. C. Colson, full particulars and illustrations of which are given. The book also contains particulars of some arched concrete roofs and bridges, including a bridge near Erbach, which has a span of 95ft., and a rise of 13ft., the concrete being 2ft. 3½in. thick at the springing, and 1ft. 7¾in. thick at the crown, and being composed of "1 part Portland cement, 1 part sand, and 3 parts carefully washed and screened Danube gravel, varying in size up to the size of walnuts." "Sigma" does not say whether he wants information respecting small arches of low rise (as for floors) or larger arches of considerable rise (as for bridges, roofs, &c.)—H.

[11396.]—**Thickness of Arches.**—A simple formula is given by Hurst, as follows:—To find depth at crown, multiply square root of radius of curvature at crown in feet by ·3 for blockstone in mortar, by ·4 for brick, and the result gives thickness at crown in feet.—G. H. G.

[11396.]—**Thickness of Arches.**—Perhaps "A Builder" will find the following table and remarks serviceable:—

Semicircular Arches, Thickness of,

Span of		Block stone.		Rubble stone.
5ft. and less		0ft. 8in.	… ..	0ft. 10in.
„ „ 6	„ „	0 9	……	0 11
„ „ 8	„ „	0 10	……	1 0
„ „ 10	„ „	0 11	……	1 1½
„ „ 12	„ „	1 0	……	1 3

Between 12ft. and 24ft. 1in. extra depth to last dimensions for every 2ft. of extra span. The above table is given in full in Rivington's "Notes on Building Construction," Vol. IV. p. 343. Another authority gives slightly smaller depths. In practice such tables require using in the light of experience, and coursing and appearance generally have to be considered. I should take the above as minimum thicknesses. Segmental arches should be slightly thicker than above, the thickness increasing in ratio to the diminution of the rise. Stone arches have been constructed up to spans of 200ft., with proportionately lighter thicknesses of crowns. Gwilt, "Encyclopædia of Architecture," in chapter on "Piers and Vaults," p. 381, says that Rondolet found "that the least thickness which an arch of equal voussoirs ought to have, to be capable of standing, was 1-50th part of the radius." In the remarkable single-arch bridge across the Dee, at Chester, 200ft. in span, the thickness of the arch at the keystone is 4ft. Arches of such large span with minimum thicknesses at keystones are always increased in thickness towards the abutments.—G. J. Bridges, A.R.I.B.A.

[11397.]—**Ventilation of Rooms.**—The quantity of air required per head per hour, in a room, to obtain a healthful atmosphere, is authoritatively stated to be 3,000 cubic feet. Thus it requires a space of 1,000 cubic feet for each person if the air of the room is changed three times every hour. As the door of a room is frequently opened, the above quantity applies only to a room closed, and having an inlet and outlet.—G. H. G.

[11398.]—**House Drains.**—For house drains the inclination should give a velocity for sewage of not less than 4ft. per second. The minimum rate of fall for this velocity, for a 4in. drain, is about 1 in 60 according to Neville's formula. For a 6in. pipe 1 in 85 will give the velocity. These are for pipes flowing one-half full.—G. H. G.

[11399.]—**Rolled Joist.**—Hurst gives the following rule:—Multiply four times depth by area of part of web below centre of gravity of the whole section, and divide by length in feet, and the result is breaking weight. Take one fourth of this for safe dead-load.—G. H. G.

◆

Colonel W. Lanton Coke, C.E., Local Government Board inspector, held an inquiry at the Soothill Nether Urban C.C. offices on Friday, relative to an application for sanction to borrow £1,700 for sewerage works, and £450 for street improvements.

A Local Government Board inquiry was held at Tonbridge, on Tuesday week, by Mr. Thomas Codrington, M.Inst.C.E., relative to an application from the urban district council for sanction to borrow £3,450 for the High-street improvements. Mr. Hobbs, surveyor to the council, explained the scheme.

Legal.

CONTRACTS AND PENALTIES.

THE Public Health Act, 1875, provides in section 174 (2), that "Every contract shall specify some pecuniary penalty to be paid in case the terms of the contract are not duly performed." The very serious question whether the absence of a penalty in such a contract made it absolutely void and incapable of being sued upon, arose in the recent case of the Prescott Urban District Council (*Times*, July 30) in an action in which they were sued for £278 for money due to the plaintiffs, the British Insulated Wire Company, for quarterly payments due for the supply of electric light and extra lamps. It appeared that there had been a contract made between the parties in November, 1892, for the supply of light for five years, under which the plaintiffs had supplied electric light down to March, 1895, and were paid for it by the Council down to June, 1894. Now the point was taken, on behalf of the defendants, that, as the contract provided no pecuniary penalty, although there was a proviso for arbitration in case of dispute, it was void and unenforcible.

After argument upon the case stated, a Divisional Court, composed of Baron Pollock and Mr. Justice Wright, held that, under the sections of the Public Health Act quoted, and upon the authorities, the agreement was not binding, and they gave judgment for the defendants. They so held apparently upon the sole ground of the omission in the contract of any pecuniary penalty to be paid in case of its not being duly performed, and they gave judgment for the defendants. This certainly seems a somewhat surprising result. There is the Statute, it is true; but although the section says every contract shall contain a penalty, it does not go on to declare that it shall otherwise be void and unenforcible. Then we have the fact that the parties have acted upon the contract for over two years, and paid money in accordance with its clauses. Nor had the absence of a penalty anything whatever to do with the claim for electric light supplied, as there was no question of any breach or non-performance which would make a penalty applicable. It is to be hoped that this case will go further; for as it stands, it seems an unjust and a dangerous precedent.

FRED. WETHERFIELD, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

A proposal is on foot to erect a mausoleum in the gardens attached to the famous Wiertz Museum, in Brussels, for the reception of the remains of the celebrated painter after whom the museum takes its name.

The corporation of Ipswich, who recently purchased the central portion of the ancient and well-wooded park of Christchurch as an addition to the open spaces in that town, confirmed at their last meeting the action of a committee who had bought a further picturesque portion containing 1,008 rods, and lying between Soane-street and the Lower Arboretum. The purchase price is £6,300, of which the odd £300 was subscribed by private donors. At the same meeting the corporation voted £1,750 towards widening Stoke-street from 23ft. to 35ft.

An important scheme for relieving the overcrowding among the working classes at Plymouth, which, next to Liverpool, is the most crowded town in the kingdom, was inaugurated last week, when the mayor laid the foundation stone of a workmen's colony of houses which the Plymouth corporation have decided to erect under the Housing of the Working Classes Act. The dwellings will consist of cottages and flats, which are to be let at rents varying from 2s. 9d. to 5s. 6d. a week, and will accommodate over 1,700 persons. The total cost of this scheme, including land, will be £51,000.

Lord Abercromby, the proprietor of Ferntower Estate, adjoining the burgh of Crieff, is about to feu for building purposes Callum's Hill, a wooded eminence to the north-east of the town. The hill, which rises 510ft. above the sea-level, will be opened up by the construction of three roads running in various directions. The principal road will be 1,370 yards in length, and another runs along the crown of the hill. The extent of the feus will vary from a quarter of an acre to half an acre in extent, and the total area laid out for feuing purposes extends to about 55 acres.

LEGAL INTELLIGENCE.

BRADFORD WATERWORKS ARBITRATION AWARD.—Mr. B. S. Brundell, of Doncaster, who was umpire in an arbitration case brought againt the Bradford Corporation by Mr. William Ferrand, of St. Ives, Bingley, in June last, has given his award. Mr. Ferrand sought compensation for compulsory easement of a pipe line through his estate at Cottingley, and claimed £3,028 for the easement, damage to property and woods, depreciation of the value of the estate, and for the sale of a small portion of freehold land. Mr. Walter Middleton, of Bingley, was arbitrator for the claimant, and Mr. T. Fenwick, of Leeds, for the Corporation. The pipe line is a portion of the conduit from the Nidd Valley works, and for the Corporation evidence was called that the full compensation should be £697. The umpire has fixed the amount at £958.

MEESON V. SHURMUR.—NORTH LONDON POLICE COURT, AUGUST 9, 1895.—The defendant, in the erection of Millfields-road Board School, had constructed a staircase of wood, and had formed the entrance doors so that only two-thirds of their width opened out, the clear width of each doorway which could be considered available for exit in case of panic being only 2ft. 2in. The district surveyor had disapproved of this construction, and had, under section 45 of the 1855 Act, served a notice of irregularity. This notice not having been complied with, he issued a summons under section 46. Counsel for the defendant took a preliminary objection that the magistrate had no jurisdiction, quoting the case of "The Queen v. Carruthers." The magistrate, after perusing the case, decided that he had no jurisdiction. Summons dismissed.

DISPUTED STREET REPAIRS.—In the High Court last week, before Mr. Justice Wright and a jury, the case of "The Corporation of the City of London v. Barnes," came on for hearing. It was an action by the Corporation against Mr. Barnes, of Halse-street, Islington Cattle Market, to recover £140 for repairs to that thoroughfare, upon which the defendant had property abutting. The defendant disputed payment on the grounds that the work in question had been done in order to raise the level of the road, that it was not a regular repair within the meaning of the terms of his lease, and that his property was damaged through rainwater flooding thereby. The jury returned a verdict for the defendant, but notice of appeal was given on behalf of the Corporation.

FATAL GIRDER ACCIDENT.—At the Marylebone Coroner's Court, on Monday, Dr. Danford Thomas held an inquest on George Scott, 39, builder's labourer. James Stevens, builder's labourer, stated that he and the deceased were employed by Messrs. Clarke and Bracey, builders, Coleman-street, E.C., and on Tuesday they were working at Messrs. Liberty's, King-street, Regent-street. At 5 p.m. they were about to pull a steel girder, 22ft. long, and weighing 314lb., up to the third floor by means of a pulley and rope. The deceased directed the operations and tied the rope to the girder. With the assistance of two other men they pulled the girder from the ground, and although it became apparent that the girder was too heavy, they continued to hoist it. The upper end had reached the sill of the third-floor window, when the rope broke and the girder fell, crushing the deceased, who was immediately underneath. Witness had suggested to the deceased that they should use a double pulley, but he chose the single one, remarking that the job was very easy. Henry West, foreman to Messrs. Clarke and Bracey, stated that the deceased had worked under him nine years, and was looked upon as a thoroughly practical man. A juryman, after examining the broken rope, said it was rotten from end to end, and ought never to have been used. Mr. Humphrey J. Bracey, partner in the firm of Clarke and Bracey, was of opinion that the rope produced would carry 3cwt. or 4cwt. safely with a fair strain; but the use of a single block imposed a heavier strain than the rope could bear. That was the first fatality witness's firm had had during 22 years. Mr. Walter Stevenson, secretary of the Builders' Labourers' Society, of which the deceased was a member, said the contention of the relatives was that the rope was perished and should never have been used for the work. He proceeded to pull the rope to pieces in the witness-box, and added that such ropes were constantly being sent out without the slightest test being made. Besides that, the man ought never to have been sent to do the job without supervision. Charles William Hewett, clerk in the Union Bank, Argyle-place, stated that he saw the occurrence. The four men were standing immediately under the girder, which they raised with a series of jerks that nearly took them off their legs. Not only were the men in a very dangerous position, but no precautions were taken for the safety of the public who were walking underneath. The jury returned a verdict of "Accidental Death," and the coroner impounded the rope.

A receiving order has been made in the case of William Hesketh, of Birkenhead and Manchester, architect.

PARLIAMENTARY NOTES.

THE TWENTY-FIVE INCH IRISH ORDNANCE SURVEY.—In answer to Mr. Field, on Tuesday, Mr. R. W. Hanbury said: Maps of the whole of the county Dublin and portions of the counties of Kerry, Galway, and Roscommon have been published on the 25in. scale, and resurvey on that scale is now proceeding in Clare, Galway, Kerry, and Mayo, and in various towns of which plans are required by the Commissioner of Valuation. The total area surveyed up to the 31st of December last was 4,751 square miles, the area published being 1,646 square miles.

STAINED GLASS.

GREENHEAD, N.B.—Messrs. Stephen Adam and Co., of St. Vincent-street, Glasgow, have just completed the Tullis Memorial stained glass window for the parish church of Greenhead, N.B, a building which is at present in the course of renovation. The memorial window, the first of its kind in the church, is to be placed in the organ recess. The window consists of three lights, divided into six sections. The subject is a double one. In the lower panels the nativity of Christ is represented, while the upper lights show forth the glory of the Saviour, whose figure dominates groups of worshipping angels.

WATER SUPPLY AND SANITARY MATTERS.

ALDERSHOT.—The existing artesian bored tube wells at the waterworks, several in number, varying in depth from 220ft. to 300ft., drawing some million gallons of water per day from the chalk, proving inadequate to meet the increased requirements, the directors have instructed Messrs. C. Isler and Co., hydraulic engineers, London, to fix additional wells for the supply of the town.

CHIPS.

The new infirmary, Lancaster, is being erected from the designs and under the superintendence of Messrs. Austin and Paley, architects, Lancaster. The various wards and other rooms are being warmed and ventilated by means of Shorlands' patent Manchester grates, the same being supplied by Messrs. E. H. Shorland and Brother, of Manchester.

After a heated discussion, and by 18 votes to 11, the town council of Wigan resolved on Tuesday to apply for powers to borrow £62,669 for the purpose of carrying out a scheme under the Housing of the Working Classes Act.

A processional cross has been presented to Kettering Church. It is of massive oak, and was carved by Miss Lindsay from the design of Mr. J. A. Gotch, the architect for the restoration of the church.

A scheme for the award to pupils of all schools situated within the city of Birmingham, and receiving aid from the Education Department, of free admissions to branch schools of the Municipal School of Art has been issued.

A fire, caused by an overheated flue, broke out on Tuesday night in the residential portion of Appleby Castle, the Westmoreland seat of Lord Hothfield. The fire-engine, Lord Hothfield's own gift to the town of Appleby, quickly extinguished the flames, but not before considerable damage had been done to the castle. The east windows are considerably damaged, in addition to the roof, which is burnt away in places. The loss is estimated at £3,000. The ancient records and pictures in the castle were fortunately uninjured.

A memorial window has been erected at Revesby, Lincolnshire, in memory of the late member for the Horncastle Division, the Hon. and Right Hon. Edward Stanhope. It is the result of a county subscription. The centre represents our Lord in Glory, whilst right and left are figures of saints commemorating various phases of Mr. Stanhope's career. That of Edward the Confessor commemorates his Christian name; St. George, St. Martin, and St. Alban, his connection with the Army as Secretary of State for War; St. Jerome and St. Wilfrid his interest in national education; and St. Thomas his official connection with our Indian Empire.

The Theatre Royal, Dewsbury, which was partly burnt down on the 4th of May of this year, was reopened on Monday week, after having undergone partial rebuilding, comprising an entirely new and much enlarged stage, new circles, boxes, stalls, &c. It has been fitted with electric light, fireproof curtain, sprinklers, and all new working appliances, refurnished and decorated throughout. The building is owned by Mr. J. A. Love, of Birkdale, and Mr. C. Sydney Ingham, of Manchester and Southport, has acted as his architect, while all the contractors are local men.

Our Office Table.

For some time past the trustees of the estate of Earl Dysart, consisting practically of the whole of the land between Richmond and Kingston, and bounded on the other two sides by the River Thames and Richmond Park, have desired to increase the commercial value of the property. The estate, however, is intersected by footpaths, and includes a large amount of land over which there exist Lammas rights, which prevent the trustees building on the land. A few years ago the Dysart trustees offered the Richmond town council a site for an isolation hospital, on condition that they would consent not to oppose the closing of certain footpaths in the neighbourhood of Ham House. A suggestion was also made for a carriage drive along the river side from Richmond to Teddington Lock, and thence into the High-road from Richmond to Kingston, at a point about a mile out of Kingston. These proposals were rejected by the council, and the matter dropped. The trustees have now caused a Bill to be drafted, providing for an extinction of the Lammas rights, and for the closing of a number of footpaths, principally those in the neighbourhood of Ham House and near the river side. It is proposed to compensate all who have recently exercised Lammas rights. The trustees are willing also to make certain footpaths in exchange for those to be closed, and offer to hand over Petersham Meadows, at the foot of Richmond Hill (now advertised to be let for building purposes), to a local authority, without consideration, to be kept for recreation purposes, and also to vest Ham Common, without consideration, in the Ham district council.

Half of the proposed coach-road to connect Borrowdale with Wastdale, and open up the heart of the Lake District, has now been surveyed, and the remainder, from the top of Sty Head Pass to Wastdale Head, has undergone preliminary survey. The work has been done by Mr. Bell, the Cumberland county surveyor, who has marked out the line of the road with whitewash. At present people going from Borrowdale to Wastdale Head by conveyance must traverse a distance of 55 miles. The distance from Leathwaite, where the new road would commence, to Wastdale Head, where it would join the road to Seascale, is, as the crow flies, 3½ miles. The new coach road would be 6¼ miles in length. It would have a ruling gradient of 1 in 12, and some portions would be much easier, the gradients ranging from 1 in 14 to 1 in 17. The proposed new road follows the right bank of the Derwent, from Leathwaite to near the source of the river; it then turns round and goes under Airn Crag, and on to the top of the Sty Head Pass, keeping Sty Head Tarn on the right. Going down to Wastdale it runs along the side of Great Gable, at a considerable elevation above the existing pony track, and then sweeps into Mosedale, and finally turns and descends to Wastdale Head. The views from the road would be as fine as any that could be obtained from any existing road to the Lake District. The cost of constructing the road has been estimated at about £10,000. The proprietors of the land are willing to give the necessary leave, and there are no engineering difficulties to be overcome.

Mr. Howard Colls is to be congratulated upon his happy idea of combining instruction with pleasure. By his invitation, the foremen in the employ of Messrs. Colls and Sons, with several clerks of works, numbering about 50, had an enjoyable excursion on the afternoon of the 10th inst. Taking train to Swanley, brakes were in waiting, to drive them to the ancient church of St. Margaret, Darenth, where the courteous vicar met the party, and pointed out the most interesting features in the building, which dates from the 7th century, and in an admirable manner, explained the various alterations which had been made at different periods, which gave proof of its history. The party then proceeded to view the remains of the Roman villa, in the immediate vicinity, which have recently been discovered. Mr. Payne, F.S.A., who superintended the excavations, attended, by appointment, and explained very fully the various portions of the remains, which are in an excellent state of preservation, and well worth visiting. The drive was then continued through one of the prettiest parts of Kent, to the Lion Hotel, Farningham, where an excellent dinner was provided. After the usual loyal toasts were duly honoured, Mr. Howard Colls expressed the pleasure it gave him to welcome so many who had been in the service of the firm for many years. It spoke well for the character of the foremen, to find that from a paper which had been passed round, and signed by the 41 foremen present, the average length of service was 21 years; he thought also that, from that he might, perhaps, without egotism, consider he was not a bad master. The health of the firm was proposed by Mr. Davenport, the senior foreman; and the toast of the clerks of works, proposed by the chairman, was briefly responded to by Mr. Wheeler. After a short time spent in the grounds of the hotel, the party returned to Swanley for town, having thoroughly enjoyed the excursion.

The Newcastle-on-Tyne Society of Antiquaries' excavations at the Roman fortress of Aesica, on Hadrian's Wall, have now almost reached their conclusion for this season. The north, south, and west gateways have been examined, the junction of the wall with the fortress laid bare, and some of the interior buildings traced out. The west gateway, it seems, has been built up at two successive periods, first one half of it and then the other. The interior buildings contain some curious furnaces, possibly the workshops of the fortress. The junction of the wall with the north-west corner of the fortress is especially interesting. The lie of the masonry clearly shows that both were built at one time, and suggests that the fortress must be of the same date as the wall. Among the lesser finds are many iron tools, bones, glass, pottery, millstones, and so forth, and two very fragmentary inscriptions. The Newcastle Society of Antiquaries will continue these interesting excavations next year.

The roofing-tile industry seems to be not a very large one in the United States, according to *Brick*, which observes the number of manufacturers is quite inadequate to the requirements. We fully sympathise with our contemporary in their desire to see more burned-clay roofs in the country. A method of making roofing tiles is described. The silver-grey or "blue smoked" tile first made in Holland is advocated as being well burned and a waterproof tile. There are objections to a vitrified tile; it is apt to warp and twist in firing, to be brittle, and to conduct the heat; but the "silver-grey" tile is burned just hard enough, and is absolutely waterproof. It is a "burned clay tile carbonised throughout," and can be made of any shape. In this country tile roofs are increasing, and many of our best buildings are now roofed with it.

The foundation-stone of the National Monument to the late Emperor William I. was laid in Berlin on Sunday by the present Emperor. Some years ago a competition committee was appointed to select a design and to determine on a suitable spot for its erection. The neighbourhood of the Bradenburg Gate was chosen as a site, and the premium had been awarded, when, in 1890, the Federal Council demanded that a fresh and limited competition should be held for designs for a memorial to be placed on the Schlossfreiheit, a strip of ground lying between the Spree and the west front of the palace. The Government selected a design by Professor Begas, of Berlin, which, when exhibited in the lobby of the Reichstag last year, was unfavourably criticised. It is, however, to be carried out in bronze on the Schlossfreiheit site; but only four million marks —half the sum demanded by the Government— has been voted by the Reichstag, who declared that no supplementary supplies will be granted.

The administration report on the railways in India for 1894-95 states that the total length of railways open and sanctioned on the 31st of March, 1895, was 21,072¾ miles, being a net increase of 650¼ miles during the year. The total length of railways open for traffic on the same date was 18,855¼ miles, being a net increase of 355¼ miles, leaving 2,217½ miles still under construction or sanctioned for commencement. The mean mileage worked during the calendar year was 18,694 miles, being an increase of 487 miles over the figures of the previous year. Of the new lines, 284½ miles are of the standard gauge, the remainder being of the mètre gauge. The proportional mileage of the various gauges open is as follows:—Standard, 10,875¾; mètre, 7,712; special widths, 267½, making a total of 18,855½ miles. The statistical return on the capital expenditure was 5·69 per cent. against 5·46 per cent. in the previous year. Subsequent to the close of the year 1894-95 and up to date (May 30), the additional mileage reported to have been opened to traffic is that of the East Coast standard gauge (State) railway, from Palasa to Berhampore-Ganjam, 46 miles, and the Bína-Guna standard gauge (native State) railway, 73½ miles. The latter has been opened for goods traffic only. During the year sanction was given to the construction of additional mileage to the extent of 651¼ miles.

The employment of nickel steel for structural purposes is a question that is probably destined to receive the attention of engineers. The adaptation of this metal for warships and armour plates has indicated its possible value for bridges and other structures. Its ductility, elastic properties, and toughness appear to recommend it for such details as plates, angles, rivets, and wire. If it be true that specimens of nickel steel tested show an ultimate resistance equal to one-third more than ordinary steel, there is every probability that for special purposes of construction the nickel metal will force its attention on engineers, despite its higher price. The reduction in weight is an important consideration in this connection.

According to an interesting paper, by Prof. J. T. Rothrock, of Pennsylvania, reported in the *North Eastern Lumberman*, great waste is perpetrated in North American forests, which is productive of great changes in the people, upon rainfall, temperature, and climate. Thousands of people never see a fullgrown tree or one that has attained the largest size under the best conditions of growth. He says there are mills which turn off 400,000ft. of lumber a day, and from statistics furnished by the Government, if the population of the United States remains what it is to-day "all the timber in the country will be practically exhausted in 60 years." Allowing for the ordinary increase of population, he thinks it is not likely that the timber will last more than 40 years. A large portion of this lumber is actually wasted, the wasted lumber being used as fuel to start forest fires, which are a disgrace to our civilisation. The destructive fires of the North-West are appalling, and it is quite time the United States Government took the matter up and stopped this wholesale destruction, which could be done, as Professor Rothrock shows, if every State paid a bounty on every acre of trees that is planted irrespective of ownership.

The North-East Sea Canal is crossed by several high-level bridges of considerable span. One of the finest of these is the Grünenthal Bridge, which has an arched span of 513·5ft. The bridge is a high-level structure, located on the line dividing the watersheds of the Elbe and Eider. It rises 65ft. above mean canal level. The members of the arched girders are crescent-shaped, with a rise of 77ft., and are slightly inclined towards each other. The ratio of rise to span 7·3 or 6·1 : 1. The roadway cuts the arched members, and these are connected by vertical rods. The weight of girders and roadway rest on the pins and abutments; but the roadway does not interfere with the expansion or contraction of the tie which connects the girders and roadway. The arched members abut on two massive masonry towers. Full details and engravings of the Grünenthal Bridge (designed by Messrs. Eggert and Greve) and the Levenson Bridge, another example of an arched-girder bridge supporting an upper roadway, are given in *Engineering*.

Trade News.

WAGES MOVEMENTS.

Ramsbottom, Lancs.—The operative painters have obtained from the employers, after the threat of a strike, an advance of wages from 7½d. to 8d. an hour. A like increase was recently obtained in the neigbouring town of Bury.

M. Barrias, the sculptor, has completed the monument to Emile Augier, which is to be erected in October in the centre of the square in front of the Odéon at Paris. The monument consists of a bust of Augier, placed on a pedestal 18ft. in height, with three allegorical figures surrounding it.

At the last moment a petition has been presented to the House of Lords against the proposed extension of the Borough of Southampton. It had been proposed to take in Shirley and Freemantle, greatly adding to the area, population, and rateable value of the borough, and an amicable settlement had been arrived at. Unless an immediate compromise is arrived at, all arrangements made for next November must fall through, entailing great inconvenience.

THE BUILDING NEWS
AND ENGINEERING JOURNAL.
VOL. LXIX.—No. 2121.
FRIDAY, AUGUST 30, 1895.

LONDON STATUES.

IT is not often that the British public troubles itself about art of any sort, and of all the arts the one it ignores most completely is sculpture. Yet, within the last week or two, it has directed an interested eye to the figure of the Duke of York in Carlton Gardens, and has even asked why the statue of Cromwell is no longer to be seen at South Kensington. All this looks like an indication of growing intelligence. Unfortunately, it has to be explained on lower grounds. Cromwell's absence was complained of for political or religious reasons, and the late Duke of York became an object of interest simply because it was rumoured that his column was unsafe. This is now denied. The Duke, it appears, is likely to remain one of the common objects of the sky, though the Protector is "stored," for want of artistic merit.

The column at the bottom of Waterloo-place was completed in 1834. Its height, apart from the figure, is the same as that of Trajan's Pillar at Rome—namely, 124ft. The foundation is 56ft. square at the base. The statue, in bronze, was by Westmacott, and was described at the time as "a splendid specimen of art, worthy of this country and of the eminent artist by whom it was modelled and cast." "It faces"—we wonder how many of our readers ever noticed which way it *does* face?—"it faces the south, the front of the statue thus receiving far more light than if it had been placed north." It was also thought becoming that this commander-in-chief should look towards the Horse Guards. The figure is 13ft. 9in. high, and its metal averages three-quarters of an inch in thickness. Judging from the views published at the time, the sculptor, or the architect, exercised a wise discretion in raising it beyond the limits of ordinary vision. It is consequently less offensive than many of its tribe. The usual criticism which the monument evokes is that there is a good deal of column to a small quantity of statuary, and profane persons have compared it to a tallow candle, in which his Royal Highness represents the snuff.

It must have been a curious type of mind which first conceived the idea of commemorating an eminent man by perching him up in the air like a pigeon just alighted. Perhaps the inventor of the memorial column agreed with Bacon in believing that greatness is seldom attained without the aid of vices as well as virtues. He remembered, it may be, the story of St. Simeon Stylites, who took up his abode on a column by way of penance; and, in placing some hero of the period in the same position, meant slily to suggest that he deserved the same penalty. But, even if this is so, insult should not be added to injury.

It is bad enough to be made a public spectacle, without being converted into a perfect laughing-stock; and Nelson, though he had his imperfections, was not so far inferior to his neighbour in Carlton Gardens that he deserved to be represented as a guy. This, however, or worse than this, is what was done with him. A more ridiculous statue than Nelson's can hardly be discovered, perhaps, in the world. That its sculptor made a great feature of the loss of an arm may be pardoned. It is so much easier to represent the absence of a limb than the limb itself, that the accident may have seemed to afford him the chance of a great success in portraiture with very little trouble. But there is not the same excuse for so arranging a coil of rope that, from many points of view, it seems part and parcel of the Admiral's body. Whatever Nelson was, he was far enough from being a ring-tailed monkey; but it is this animal, and not a human being at all, who might easily be supposed to have acted as the model for the great abortion of Trafalgar Square.

Many of the London statues, however, have not even the merit of being laughable. Sir Robert Peel, at the end of Cheapside, succeeds perfectly in what all Englishmen are said to aim at—namely, in having nothing, either in person, dress, or expression, to mark them off from their neighbours. The same may be said of Sir Rowland Hill, at the back of the Royal Exchange, and if his statue and Peel's took a midnight walk—as did that of the Commendatore in "Don Giovanni"—and then by way of a change stepped on each other's pedestals, few of the citizens would be likely to detect their frolic. But they are far too solemnly respectable for this. No thought of such levity will ever enter their heavy heads; no such movement will ever disarrange the perfect fit of their faultless frock coats. William IV., indeed, may fling off his blanket —which, in the recent sultry weather, seemed painfully hot for so stout a man—and may startle the 'bus-drivers, as they come off London Bridge, by appearing *in puris naturalibus*. He looks capable of it; but respectable statues, in modern costume, have to stand patiently through summer's heat and winter's cold. To see, for instance, the fortitude of Mr. Peabody—sitting bareheaded in his inclosure, like Mr. Pickwick in the pound, when snowflakes are settling on his hands, his head, and even the very tip of his nose—is enough to bring tears to the eyes of a stoic. The philanthropist who helped to shelter so many working men surely deserved some kind of shelter for himself.

We might go all through London noting failure after failure. The public admit it, and say, with a kind of pride—the pride of people who excel in so many great matters that they can well afford to confess their incompetence in a small one—"We are not an artistic nation." But the faults of London statues do not often rise to the dignity of being artistic faults. The greater part of them are faults which indicate the absence of ordinary intelligence—not so much in the sculptor or the modeller as amongst the people who give the sculptor or the modeller his directions. The process is after this fashion: A committee is appointed and subscriptions are asked for to commemorate some eminent man. This committee settle, before consulting any artist, what form the memorial is to take. They are guided by precedent. Other committees have put up bronze statues on pedestals, therefore, they decide to have a bronze statue on a pedestal. They see what has come of the previous ones; but they are too insensible, too unconcerned, too unimaginative to aim at anything better. Common-sense would tell them that an outdoor statue in a cold, dull, smoky town like London is an absurdity—a thing that for two-thirds of the year simply makes one shiver to look at it. Common-sense would tell them that if they must have an outdoor statue where sunshine is so scarce, the very worst thing they can do is to have a black one. Common-sense would tell them further, not only that bronze with us soon turns black, or nearly black, but also that it is a material chiefly adapted for figures with a great deal of action and very little drapery. It is an excellent substance for displaying extended limbs and energetic attitudes; it is the heaviest and deadest of all things when a mere expanse of coats and trousers has to be represented.

But in dealing with matters which pertain to art, committees take leave, not only of common sense, but of all their senses. They only ask what the previous committee did, and straightway do the same —just as a runaway sheep sees the sheep before him leap over a precipice and break his neck, and with the result in full view, leaps at the same place, and does the same thing.

The London statue, therefore, is predestinated to failure, even before it gets into the artist's hands. What can he make of it, under such a sky, in such an atmosphere, and, with modern dress, in such a material? He cannot represent a prime minister as a dancing faun, or a corpulent chancellor of the exchequer as a *discobolos*. He is bound down to ordinary clothes, or, at most, robes of office, and either of them imply a great shapeless mass of bronze as the bulk of his figure. All that remains to him is to put what expression he can into the head and the hands. How far he succeeds there, few of us know. His statue's countenance soon gathers blackness—in a very literal sense. A negro, accustomed to watch the indications of the human face divine under such conditions, might see gleams of intelligence in it; but to the average European a dozen bronze figureheads have as strong a family resemblance as a dozen sweeps. If a memorial committee want to realise what sort of thing it is that they are really going to set up, let them blacken their own hands and faces, and stand by turns on the top of the nearest garden-wall. They will then be of the same hue as their proposed casting, and would be seen in much the same position —that is, dark against the sky. If, after trying the experiment, they are filled with mutual admiration, then let them go on and prosper.

The sculptors, however, deserve some of the blame. It is not their fault that their works turn out badly under these senseless conditions. But it is their fault, in the past, if not in the present, that such conditions have become common. It is chiefly they who have set up the works of Greece and Rome not only for universal admiration—which is right—but also for universal imitation, which is absurd. Outdoor statues were reasonable enough in a warm, bright climate like that of Italy. Bronze statues were reasonable for the lightly-draped class of figures which, in many attitudes, require something stronger and tougher than marble. But it shows a want of consideration, worthy of committees themselves, to advise the use of bronze in London, simply because the ancients used it in Southern Europe. The question is not what the Greeks did at Athens, but what they would have done in modern London if they could have been set to produce a memorial here, and we may be very sure they would not have produced a Peabody, or a Peel, or a Duke of York at all like those which greet us in the City and the Park.

It is time we gave up detached statues standing, miserable and unprotected, in the open air. It is time we gave up making any outdoor statues of bronze, unless, at the very least, fashions change enough to let something of the human form be seen throughout them. We have had two centuries of costly experiment, and if experience can teach us anything, it is time we took its lessons to heart. Indoors, in halls and museums and galleries, detached figures can be appreciated. Out of doors we have made almost uniform failures of them, and our nearest approaches to success have been alto-reliefs like those at the Albert Memorial. There is much more to be done in that direction, in the combination of boldly-designed figures with architecture as a setting and a background, and in that direction, we may hope, the belated intelligence of committees will, before long, permit us to move.

IS A CONTRACTOR DESIRABLE?

WHETHER it is better to carry out a building by contract, or to become one's own builder, is a question which still occupies the attention of many people, especially building owners who have spare time and aptitude, and who imagine they can save, and also municipal bodies, who think the latter plan is more economical, and the work done is better. We have known a few proprietors who have carried out their own buildings without a contractor with some advantage to themselves. A large landed proprietor, for instance, who burns his own bricks, or owns a quarry may erect a house or build farm buildings or labourers' dwellings on his estate by employing labour and purchasing the necessary materials in the open market. Or an employer who engages regularly a large number of hands, bricklayers, carpenters, and other workmen, and who can keep them continuously employed may very profitably erect dwellings on his estate. A corporation has facilities for doing work in the same manner when they have workshops and plant, and proper agents or surveyors; though in some cases corporations have not found the system lucrative, and, if we are rightly informed, the London County Council have tried the plan with doubtful results. The success or non-success of the plan will invariably depend on the competence of those who are intrusted with the work. It is not merely buying materials in the cheapest market, but the mode in which they are converted and used; how to set about the work, to utilise the labour to the best advantage.

The engagement of men suitable for the work, choice of methods, and the superintendence are vital conditions. Any defects in materials or workmanship on this system have to be made good at the cost of the owner or corporation; they cannot be thrown on the contractor. Two important conditions seem necessary. The men employed ought to be continuously engaged upon similar work, and the workshops ought to be sufficient, and well equipped with the necessary apparatus and plant. In a paper on this subject, a writer, Mr. H. A. Elton, speaking of the two modes of carrying out works in the Royal Engineer establishment, says:—"The carrying out of works under this system is practically impossible, except for public bodies, as workshops must be erected, machinery set up, and materials purchased in large quantities, if economy is to be considered at all; and a large staff of permanent employés is necessary for the efficient execution of the work." The same authority says, it is extremely difficult when works are scattered, as they would be in those of a corporation, to prevent robbery of material; old men get taken on works who are unable to do a full day's work, and much time is wasted in waiting for jobs and materials. These are considerable drawbacks to public bodies carrying out their own building. No less objectionable is the temptation to charging an excess in one work to another, or of equalising the expenditure on different works for the sake of appeasing the corporation or the ratepayers, so that it is very difficult to find out what has been the cost of any particular work—a proceeding which often leads to charges of favouritism and corruption. For these reasons, Mr. Elton thinks it desirable that "the execution of works through a contractor is desirable in all cases, except where the work is very extensive, and likely to be carried on at a uniform rate for a great number of years." He goes on to say allowance is rarely made for interest on sums paid for materials kept in stock, depreciation of machinery, plant, waste of time and materials, loss due to employment of infirm workmen, and for these reasons he says:—"I am convinced that the actual cost of works carried out on this system is greater than that of similar works executed by contract when care is taken that the information furnished to the competitors is definite and exact."

But there are evils also in contracting. Every architect knows that it is very difficult to maintain the standard of good materials and workmanship; how irresistible is the temptation to evade the specification when a low tender is chosen. Again, the workman does not get his fair share in the profits of the business. Besides, a general opinion prevails that it is better to get one's own materials than to trust to another whose chief business is to make a profit. No doubt; if one can be sure of selecting with judgment and of getting it converted or used with skill, but not otherwise. Where the contractor is a skilled tradesman himself, or a competent and responsible man of business, the contract system ought to produce satisfactory results. It is because people regard cheapness first, and workmanship as a secondary consideration, that they have to endure the speculative element with all its drawbacks. If only the building owner was satisfied with obtaining a reasonable price, he would have little to find fault with. For this purpose the competing builders must be provided with quantities and specifications that are definite and complete. Any uncertainty introduces the speculative into their calculations. The question of schedules is a material consideration. Sometimes the contractor takes work under a schedule the prices of which have been fixed, and he puts a percentage on these prices. There are advantages in this plan when the class of buildings has been considered, and the prices adjusted to the locality and to the circumstances. The surveyor who prices knows perhaps better than the contractor the real requirements, and a more exact tender is obtained.

For repairs and small items, this form of schedule has one merit: it prevents guessing, and any elaborate kind of work is more exactly estimated than it would be if each contractor had to affix a price. But the usual form of quantities on which the prices are filled in by the contractor himself is more suited for works of an extensive kind. The contractor is enabled to take advantage of any special facilities and machinery or plant he possesses, and therefore to estimate certain items at a lower rate, to the manifest gain of the employer. If the actual quantities of materials and workmanship are put down and priced, neither party ought to be a loser, as the actual work is paid for, no more and no less. But it is not always possible to determine beforehand the exact quantities; for example, the number of yards of excavation or concrete for foundations, and in such a case a priced schedule has the advantage, the actual quantity being obtained by measurement. The lump-sum tender is therefore better adapted when the actual quantities can be taken pretty accurately. When they cannot be so ascertained, the contractor must either be paid for too much or for too little. In the latter case he sometimes endeavours to recoup himself by evading the terms of the specification. If, however, the superintendence is efficient, we do not see why the contract system, with all its faults, should not be quite equal to the plan which makes every man his own contractor.

BUILDING AIDS.

THEY say it is a poor workman who quarrels with his tools; yet, admitting the force of the old adage in one sense, it is equally true that to the instrumental agencies, materials, and means he employs the artist must look for much of the success of his work. The architect seldom troubles himself much about those facilities and mechanical aids which are of the utmost concern to the builder and contractor. To take, for example, the simple matter of facilities for carriage of goods and transport—say, for instance, the conveyance of materials, like stone or brick—to a building site; what a vast difference it makes to a contractor in his tender whether the carriage is easy or difficult, whether the quarry is within access, or the transit of materials can be accomplished without delay or expense. Or, in the matter of conversion or handling, how much depends on machinery for conversion, and appliances for haulage and lifting, pumping, and other operations? The "scaffolding"—to use the term in a wide and figurative sense—is becoming a very important item in building operations, and one which the architect, no less than the builder, ought to know something about. All the aids and agencies, mechanical and otherwise, which are external to the building, or which are used as temporary expedients by the builder, may be included under the phrase. The last quarter of a century has added greatly to the number of those mechanical aids which are now so much used on our larger buildings. The development of scaffolding for the lifting and handling of heavy masonry and ironwork is worth notice. A timber-framed scaffold in the shape of a huge tripod, for carrying a steam-crane, is placed in a central position, so that all parts of the building can be brought within the radius of the jib. By its means the heaviest material can be lifted and handled with the greatest nicety, and swung round just where it is wanted. Beside the giant arms of the steam-crane the old crab and tackle is a pigmy operation. Overhead travellers are now used very extensively for a similar purpose, and one of the latest developments we hear of is a hydraulic field-riveter, which is in use in France and America, by means of which a large proportion of the rivets in a bridge can be driven by a machine suspended from a trolley that travels transversely across the bridge upon girders, which also are moved longitudinally on a track. Thus, the riveter-traveller commands the whole bridge. In these and like aids the architect has a special interest, for they not only facilitate building operations, but enable the work to be performed with greater accuracy. Building plant is becoming so multifarious and scientific, that it is beginning to form an important branch of the builder's art, and it may be of interest if we cast our eye over a few of the many appliances which are employed. Of course, there are those who will assert that these mechanical aids have rather hindered the artistic impulse, and have brought about a mechanical mode of execution detrimental to real handiwork. "Look at the great works," they will exclaim, "which were erected hundreds, aye, thousands of years ago, without those appliances—have we beaten them?" In some respects aids of this kind have been prejudicial. For example, machine labour in joinery has interfered with artistic craftsmanship by cheapening labour; but in other departments, as in lifting, handling materials, pumping, excavating, these aids have been helpful. We may not have surpassed our forefathers in architectural skill; the fault is not, however, ours, but the system which places the mechanical facilities we possess in the forefront, in encouraging cheap labour. Labour-saving plant is not used as it should be, to save time and reduce manual labour, for cutting stone and timber in bulk, but for the purpose chiefly of competing with the trade, of encouraging cheap repetitions, and of enabling the contractor to underbid. Thus, in a large work, in which excavation forms a considerable part of the labour, the contractor who has certain mechanical aids can compete advantageously against the man who has an inferior plant; but, if he likes, he can employ them to reduce the price for excavation far below what it should be, allowing for interest on capital invested. So, again, the large machine-joiner can compete ruinously against others in the trade who have no plant.

Many of the trades connected with building have been almost revolutionised by mechanical apparatus. In excavating and foundation work on a large scale, we have now various machines for pumping, for excavating by hydraulic drills and otherwise, for hoisting materials, for boring rock, breaking stone, &c. To lay foundations at great depths below water for bridges, or other structures, the pneumatic caisson has taken the place of other methods. Many of the piers of our great bridges have been constructed by the aid of the compressed-air or pneumatic process. By this method the air is compressed into a box or cylinder, which drives the water out, enabling the material inside to be excavated and removed from the interior. The ingenious invention of the "air-lock" has enabled the men to enter and leave the working-chamber with comparative safety. As our readers know, the air-lock is simply a contrivance by which the excavators can enter the working chamber under air-pressure; it is an air-tight box with two doors opening inwards towards the pressure in the shaft which connects the caisson with the outside atmosphere. A section of the shaft, or preferably the top of it, may be used as an air-lock. The doors are made to close against rubber gaskets, so as to exclude the air, the pressure of which keeps them shut. Materials, such as sand, mud, and gravel, can be removed by the sand or mud-pump, or by blowing it through pipes, and various patented machines are used for this purpose. Then there are "grabs" used in sinking cylinders for removing hard deposits, rock drills for rock-boring, pumping apparatus, and sundry other plant which the large contractor employs. All these improvements have rendered it possible to execute large engineering works with ease and despatch. They form, in fact, quite a distinct branch of the trade, in which the resources of machinery—hydraulic and pneumatic—have been called into exercise. Their great merit is that they have economised manual labour in the execution of foundation work, and have in some instances reduced the cost 20 to 30 per cent.

The assistance rendered to other trades by mechanical appliances has been considerable. We have referred briefly to the improved scaffolding, hoisting gear, and means for handling heavy materials. Bricklaying and masonry may be said to have developed in proportion to the means of moving and lifting. With the improvements in crane construction and their erection on gantries to command a building, a great saving of labour must have been accomplished. To what extent these facilities of hoisting have developed our architecture in which larger materials have been used it would be hard to say; but there is no doubt greater masses of stone, larger monoliths of concrete, and heavier girders are employed than formerly. These aids have also favoured the erection of higher buildings. One advantage of these modern modes of raising and adjusting materials is that the building is not obscured by a forest of scaffold-poles, through which a very imperfect view of the edifice is obtained, for all the staging and tackle rise, as it were, with the walls, and it becomes possible for the architect to correct any defect which may appear as the work proceeds. With the ordinary bricklayer's or mason's scaffold, with its number of standards placed close and braced and its succession of putlogs and plank platforms, little can be seen of the building as a whole. The modern "gantry," which one sees over the foot pavement of buildings in towns, is now all but the exception. The frames of squared timber resting on sleepers on the pavement, with uprights and braces, can be placed at any convenient distance apart, and upon the heads of the frames joists are laid for the platform of scaffold-boards. Upon frames of this kind "travellers" are also placed, these running on iron rails spiked to the heads of the frames, and the trolley, which is really a trussed carriage upon wheels on cross-beams on which a crab rests, completes an arrangement that affords every facility to the workmen. Of late years improved modes of imparting motion to the traveller by means of cog-wheels have been devised, and the methods of constructing the gantry itself are also worth attention. Instead of frames, the trussed beams which carry the traveller are supported on framed legs, which in turn travel on railed sleepers resting on the ground. In this manner two opposite motions are given to the traveller, one longitudinal along the front or length of the building, and the other transverse to it. A steam-winch completes the apparatus. A more advanced kind of scaffolding is that we have described as a large tripod or three-legged erection situated over the centre area of the building, and carrying a triangular platform which supports a derrick crane. It is well for the architect to make himself familiar with the construction of these erections, and how they should be put together. For large operations, the legs are really square towers of timbers, braced together in several stages, and of any height to command the whole area of the building. One of these forms the support of the crane. The towers at the top are connected by trusses of timber which carry the joists and platform; the crane is above one of the towers, and the stays are fixed to the other two. The base of the towers should be weighted with masonry to a weight of twice the load to be raised, and the derrick must be securely anchored to the ground at the bottom of each tower. The improvements made in the derrick crane, the wheel at the top of jib, and the safety appliances to prevent accident, are matters which deserve attention by those who write specifications for these structures.

Architects ought to make themselves acquainted with these and other appliances, and not leave too much to the contractor. A well-constructed scaffold or gantry is of the utmost importance to the work, as it insures a more careful supervision of the building; but a weak and shaky scaffold will deter the architect from inspecting the upper portions of the work, and the workman will use it with less confidence. In these matters a great deal is left to chance. A properly constructed scaffold is some guarantee at least that the building will be creditably performed, and that the work will not be scamped when the preliminaries and instruments of its erection are well selected and skilfully devised.

CAST IRON IN BUILDER'S AND CONTRACTOR'S WORK.—II.

By Joseph Horner.

I DO not propose to describe the methods by which cast iron is smelted, since that would be outside the scope of these papers. Cast iron can be obtained to-day in all conceivable grades, from the best cold-blast down to the cinder-pig, the veriest rubbish conceivable. Foremen and furnacemen have learned by long experience to mix different brands in such proportions that any desired result can be obtained. Practical men know how to design the forms of castings so that their several parts shall be subjected to equal and uniform strains, and so that neither at the time of cooling nor subsequently will they be liable to fracture within the safe-working load. So that we may say that there is no essential obstacle in the way of the permanent use of cast iron for a large number of purposes in constructive work. And, as regards bad design and inferior workmanship, one is just as liable to find that in wrought iron and steel as in cast iron.

In treating of cast iron we take up a metal which is the crude basis from which all wrought iron and the many classes of steel are produced, and yet the chemical differences are but slight. If we take a piece of average cast iron and fracture it, we find that it breaks very readily with a short, entirely crystalline fracture. The colour is a bluish grey, not very bright, unless it happens to be what is called in the foundry white iron. This will contain from 2 to 4·5 per cent. of carbon, with a variable admixture of other elements. The same cast iron puddled and freed from some of these elements, and deprived of practically all its carbon, containing only a trace per cent., becomes so tough that it cannot readily be broken by hammer-blows, but must either be nicked first, or bent a good deal before fracture will take place. And when the fracture takes place slowly, the ruptured surfaces are wholly, or almost wholly, fibrous. The addition of a little carbon, say to the amount of one-tenth per cent., will produce mild steel, one-third as strong again. The fracture of this will be fibrous or silky, but the colour will be much brighter and the grain finer. Successive additions of carbon, up to, say, a maximum of from about one to one and a-half per cent., increases the strength, nearly doubling that, but diminishes the ductility, and then the fracture again becomes highly crystalline and short, but the grain is much finer, and the fractured surfaces are very lustrous. In addition to this, the steel has acquired the capacity of being hardened and tempered, properties not possessed in any degree by the cast iron, or its other products, wrought iron and mild steel.

When a contractor orders work from a founder, he does not trouble himself much about the chemical composition of the iron. To tell him that the iron contains certain percentages of carbon divided in certain proportions between graphitic and combined, so much silicon, phosphorus, sulphur, and so on, would not tell him much about the quality of the resulting castings. And although a good deal has been written about the chemistry of iron, notably by Lowthian Bell, Turner, Keep, and others, it is a fact that scarcely any foundrymen understand anything about it, that is in the sense of its affecting their daily practice. A foundryman will tell you the quality of a piece of iron by simple inspection, and seldom be at fault; but if you talk of percentage proportions of elements, he will shake his head and advise you to go elsewhere. I must confess I am with the foundryman rather than with the chemist. I know a good casting when I see it, and I know that many other matters besides chemical composition have to be borne in mind in the production of that casting. It is to this aspect of the subject that attention will be given in these articles—the practical side. In order to render these papers useful to students, as well as to others, I shall allude by-and-by to the effects of certain elements on the productions of the foundry; but, in the main, I shall write as a practical man for practical men.

There are several varieties of foundry iron, and each broad class has well-marked characteristics of its own; so that a practised eye can distinguish one from another by inspection. These varieties are known as grey, mottled, and white; but they merge imperceptibly one into the other.

The grey iron contains the maximum of carbon in an uncombined state. That is the carbon present is not chemically combined with the iron, but is mainly in the free or graphitic state. About one per cent. will represent the quantity in combination. The visible carbon occurs in black shiny flakes, which are clearly visible when the iron is fractured, if the light be shaded by the hand so that it does not fall directly upon the fractured surface. If such iron is machined, some of the graphite becomes separated in the form of dust. If such iron be pounded and levigated in water, the carbon will separate out from the iron. Such iron is soft, its tensile strength is low, it is fluid in the ladle, and quiet, throws off few sparks, becomes rapidly covered with scum, runs freely into the finest castings, and is therefore used for ornamental articles. It is also employed for the general run of founder's work, as columns and pipes, structural castings, and work for which exceptional strength, closeness, and hardness of grain is not required. The bulk of the grey iron used comes from the Scotch furnaces. But it is not so much used alone in the form of pig, being "open" in the grain, as when mixed with scrap of all kinds.

The second class of iron is the mottled, and the name well denotes the appearance of the fractured surface. It is neither grey, nor white, but partakes of both characteristics. In this the carbon is partly graphitic, but also largely combined. The appearance of the fractured face is fairly bright; the crystals are not so coarse as those in grey iron, but have a much cleaner appearance. The mottled iron is very tough, and is used for the best class of castings, those, namely, requiring great strength and good wearing surfaces. Mottled iron is produced by the judicious mixture of grey pig with best selected scrap. For the best castings it is often specified that the mixture shall be remelted. That is, the mixture will be made, cast into rough pigs, broken up, and remelted for pouring into the actual mould.

In reference to the coarseness or fineness of crystals of cast iron, it must be borne in mind that their size depends much, or even more, on the mass of the casting in which they occur, than on that of the quality of the metal itself. Iron which cools slowly, such as that in the heart of a large casting, will contain crystals much larger than that which cools rapidly on the exterior of the casting, or throughout the entire mass of a thin section of the same casting, or in a small casting. In the heart of a large casting the crystals are always coarse; in a thin plate they are always small.

The third class, the white iron, is not used for builders' purposes. It is employed only in special classes of work, chiefly for those which have to be chilled, in some cams, or tumblers, and in some parts of structures subject to the attrition of sand. It is too hard to be machined, and, though strong, it is too brittle for structural purposes. A large portion of its carbon is in the combined state. The aspect of a fractured surface is silvery white, and the crystals needle-like. It is poured with difficulty into the mould, and will not do at all for fine castings, being too thick and viscous. It is readily recognised in the ladle by its violent ebullition, throwing off of quantities of sparks, with little scum. Under different treatment these irons change their characteristics with chameleon-like readiness. But of this more anon.

There are three ways in which the quality of cast iron is tested. One is by fracture and inspection, another by means of test-bars, the third by actual tests of castings. When a founder wants to judge of the quality of pig and of scrap, he just calls a labourer and makes him break a piece or two under the sledge, and looks at the fractured surface, noting also the way in which the iron breaks, whether readily or with difficulty. The engineer gets test-bars cast from the same ladle of metal as that used for the casting the quality of which it is desired to ascertain. Sometimes in big contracts it is specified that a certain proportion of the actual castings supplied shall be selected at random and broken, in order to judge thereby of the quality of the whole. Let us look at these in turn.

In reference to the method of testing by fracture and inspection of the broken surfaces, it is obvious that this is only practicable in the hands of practical men. A man accustomed to this can judge the quality of an iron as well, if not better, than any test-bar will show. He can not only tell whether it is strong, but also whether it is likely to draw when cast, and whether it borders too closely on other qualities of iron which it is desirable to avoid; whether it would be better for a little more admixture of scrap or pig or not, and whether it would be better for remelting or not. Most foundrymen judge their iron in no other way than by inspection. A good deal is noted at the time of breaking. Some iron takes a lot of breaking, blow after blow being delivered before any sign of fracture occurs. Very tough iron, if not very thick, will bend sensibly before breaking. I once saw an old clock face, only about $\frac{3}{4}$in. thick, become quite dished before it would fracture under hammer blows. That, however, is very exceptional, but it is quite usual to see the best scrap become indented with bruises from the sledge, or ball, before any sign of cracking occurs, and one may be sure that is good tough iron before the fractured face is inspected. In reference to the inspection of the fractured face, that I cannot describe beyond what I have done when noting the essential differences between grey, mottled, and white irons. Experience alone can render one familiar with these appearances, and, of course, such appearances, though familiar enough to the founder, cannot be used by the purchaser. The founder too can tell the quality of a casting, after it is made, by looking at the fractured runner, or ingate, but the purchaser could not, even if the identical runner were handed to him. Hence the reason why test-bars are resorted to.

Test bars are generally made 3ft. 4in. long, by 2in. deep, by 1in. thick. When laid upon knife edges 3ft. apart, the 2in. depth standing vertically, and gradually loaded at the centre, they should stand a load of from 30cwt., to 32cwt., and deflect from $\frac{3}{8}$in. to $\frac{1}{2}$in. before fracture. 28cwt. is the minimum load at fracture usually permitted. These test loads and deflections are recognised measures of the strength of good iron for average structural work. Higher breaking results are sometimes obtained, but they are exceptional, and are perhaps of less practical value than the mere figures would seem to show, because of this; that very strong iron is liable to "draw," and thus become a source of weakness in another way.

In reference to the best methods of obtaining test-bars, it it obvious that it is not sufficient to take a founder's word that a given test-bar is made of the same metal as that poured into a given casting. That might be safe with honourable firms, but it cannot be relied on as a rule. It is usual to send an inspector at the hour of casting, to see the test-bars run from the same ladle of metal as the castings. He then stamps the bars with his initials or other mark, and reserves them for testing. Another way is to run bars on the castings themselves, to be removed only in the presence of the inspector. This is a safe way, and one or other of these methods should be adopted; since without such precautions test-bars are liable to be "faked." Sometimes they have been cast from metal quite different from that put into the castings of which they were represented to be a sample, instead of bar and casting being poured from the same ladle. To be sure of them, they must either be cast under the eye of an inspector, or cast on the work itself.

For the general run of work, the practice of casting test-bars under proper conditions is sufficiently indicative of the quality of castings. But there are some classes of work for which even these do not adequately represent the soundness of the castings. As we proceed, I shall explain some of the causes which produce this unsoundness, or uncertainty. The causes are "draws," and shrinkage stresses, blow-holes, unequal thicknesses of metal, scabs, and general porosity. These have no relation whatever to the strength of the test-bars; but are caused by bad design and bad workmanship. For these reasons it is sometimes specified in some classes of work in which absolute soundness is considered essential, that a certain percentage of the actual castings, perhaps one, or two per cent., shall be selected at random, and broken up for inspection. The cost is slightly increased thereby; but such a method of testing is perfect. It guards the purchaser completely, because the founder will not allow any one casting known to be faulty to be passed, since that particular one may happen to be selected for the purpose of inspection. Such fracture shows not only strength, but soundness and closeness of grain, the presence or absence of draws and blow-holes, the accurate setting of cores, thickness of metal, and also whether the casting has been doctored in any way, by filling up blow-holes with "beaumontague." Having now taken a general survey of the nature and characteristics of cast iron, we shall be prepared to make a minute study of the same, and of its applications.

NOTES FROM PARIS.

ONE of the first matters to be decided at the next session of the French Parliament is that of the metropolitan railway. The Ouest Railway Co. will have rights to construct a new line from Courcelles to Passy and the Champ de Mars, and also a line from the Invalides to the Cluny-square, passing under the Boulevard Saint Germain. These lines should be in full working order by 1900. Permission will be given to the Orleans Railway Co. to prolong the Sceaux line as far as the Grande Augustins quay, passing under the Boulevard Saint Michel, and to construct a line from the Cluny-square to the Orleans Station, forming, thus, the prolongation of the new Ouest line from the Invalides to the Cluny-square. This line will pass under the prolongation of the Sceaux Railway, under the Boulevard Saint Germain, regaining the town level at the Pont Sully, and following the Saint Bernard quay as far as the terminus.

In view of the above important work, the Municipal Council are considering the following questions in the interest of the landholders and house proprietors having property along the proposed lines. The Prefect of the Seine is required to carefully look after the interests of the inhabitants of the Boulevard Saint Germain, and to take all measures necessary to enforce a proper respect of their rights by the railway companies. The work of constructing the underground tunnels should be done in short lengths, having close intervals, allowing proper public circulation and traffic. As far as possible, the work should be done by means of perforations, similar to those made for the work of the Clichy siphon, in order to avoid as much as possible the upsetting of the public roads. In cases where it is absolutely necessary to make cuttings from above, the half of the roadway must be left free for traffic. In no case may the pavements and the traffic thereon be interfered with, and no deposits of materials will be allowed on the roadways or boulevards.

The Paris Town Council will do well to take strict measures for enforcing the respect of public and private property during the construction of these new lines, for much dissatisfaction was expressed by the landlords and tenants of the buildings on either side of the Boulevard St. Michel during the construction of the lately-completed prolongation of the Sceaux railway.

A very interesting article appears in one of the Paris papers concerning the past and present value of land and buildings of the capital. The present value of the land and buildings of Paris, not, of course, including furniture and such-like property, has been calculated as nearly as possible as being £680,000,000, the number of houses being 83,000. Referring to the past value of land, it is stated that under Henri IV. certain ground bordering the old streets of Seine and Jacob was sold from 6d. to 3s. 6d. per square mètre (nearly 11 super. feet); in 1606, Queen Marguerite de Valois bought, in the Rue des Saints Pères, a portion of the celebrated Pré-aux-Clercs, at $1\frac{1}{2}$d. the arpent, or acre and a half. In 1623, Marie de Medicis bought 20 acres of land at a little less than 1d. the mètre for the Luxembourg Gardens; in 1630, the ground of the now immensely valuable faubourg Montmartre was worth 5d. the mètre. In the beginning of the 17th century, a large quantity of land planted with vines, and now forming the centre of Paris, was sold at one-tenth of a 1d. the square mètre. The average price of houses in the old faubourgs of Paris was a hundred years ago about £220 each; to-day the average price is £2,700. In the 14th century, a large number of houses in the centre of Paris were sold at about £4 to £8; under the reign of Louis XIII. the value increased very fast, owing to the establishment of commercial quarters. The book from which these particulars are taken, "The History of Property Since the Year 1200," by Comte d'Avenel, contains a quantity of the most interesting information regarding the sale of property since this date, and that of various historical buildings and dwelling-houses still existing at Paris.

The Holy Women weeping over the body of Christ at the foot of the Cross was the subject given to the competitors for the Grand Prix de Rome, for painting. The subject, offering great facilities, and by no means liable to the reproach generally made that the programmes often obliged the students to depict personages almost unknown, did not, however, bring out much remarkable work; several of the competing pictures contain very noticeable errors, and the painters of others seem to have fallen into realism of very bad taste in their painting of the face and body of the dead Christ. One picture shows the Virgin as a very old woman, the artist seeming to have forgotten that the mother of Christ had scarcely reached fifty years of age at the time of the death of her Son. The Grand Prix is awarded to M. Gaston Larreé, pupil of M. Bonnat. His canvas contains three figures, those of the dead Christ and the two Holy Women; these are very cleverly treated, the painting showing the solid qualities of drawing and painting always noticeable in the work of the pupils of M. Bonnat. The picture does not contain much originality or much sentiment, but is quite in keeping with the traditions of the Grand Prix. The second prize is awarded to M. Paul Albert Laurens, pupil of MM. Cormon and Benj. Constant, and son of the well-known painter, M. Jean Paul Laurens. The execution of the picture is exceedingly clever; the young artist has already shown many proofs of great talent in pictures exhibited at the Salon since a few years; the last one, a Pasiphaé, attracted considerable attention. It is expected that M. Laurens will, before the end of the five years during which he may compete for the Grand Prix, carry off this prize. The third prize is awarded to M. Jules Guinier, pupil of MM. Jules Lefebvre and Benj. Constant. The work of this young artist is very clever, and the expression of his faces exceedingly truthful. The general tone of the painting is, however, open to criticism.

The subject given to the competitors for the Prix of Architecture was a palace for exhibitions and festivals. The Grand Prix is awarded to M. Auguste Patouillard, pupil of M. Ginain, and second prize of last year, for a building of a certain character, with a very effective dome and important principal entrance. M. Eugene Duquesne carries off the second prize for a building of rather pleasing silhouette. This young architect is pupil of M. Pascal. The third prize is awarded to M. Tony Garnier, pupil of M. Blondel. His design is one of the most original, but the details are somewhat complicated. This competition, although of a certain interest this year, owing to the programme being one which will occupy the attention of a large number of architects, who will shortly compete for the buildings destined to replace the Palace of the Champs Elysées for the year 1900, does not result in any work or design calling for special remark.

It is proposed to restore the original aspect of the Pont de la Concorde under the Empire and the Restoration, by replacing the statues of celebrated men on the immense pedestals of the parapets, which have remained unoccupied since Louis Philippe. The ten or twelve colossal statues erected on the Pont de la Concorde by the Restoration in 1827, replacing the immense statues of generals raised under the Empire, were taken down under Louis Philippe, and placed in the Court of Honour at Versailles, for it was the opinion of the architects and engineers of that time that their enormous weight was sufficient to compromise the solidity of the remarkable work of Peyronet. This bridge was commenced in 1787, and finished in 1790, and constructed in its upper portion with stone coming from the demolished Bastille; the heavy statues placed on the parapets by Napoleon and Louis XVIII. threatened to bring about the ruin of the bridge, and were taken down in 1841. It would, therefore, be very absurd to-day, when the traffic over the bridge is increased tenfold, to re-erect the old statues with their enormous dead weight. It is, however, necessary with regard to harmony and proportion that the statues should be of very large dimensions. It will, therefore, become the duty of chemists and metallurgists to unite themselves with the sculptors, and furnish a light and malleable alloy, such as aluminium, combined with some other metal, for the construction of the fine statues with which it is proposed to ornament the Pont de la Concorde before 1900.

The monument raised to the memory of the late President Carnot has been inaugurated at Nice. It consists of a semi-spherical base of native stone, surmounted by a marble pedestal and shaft, on which is sculptured a young child holding a garland of flowers, a bronze bust of Carnot crowning the whole. The monument is the work of M. Tournaire, architect, Prix de Rome, and M. Convers, sculptor.

The competition for the erection of a monument to Carnot at Lyons is now open, the programme having lately been made known. The competition will be a double one, the preliminary work asked for being a general plan and sketch on a small scale, and a plaster model of one-twentieth full-size. The date for sending in is December 14th next. A sum of £120 will be divided amongst those who are admitted to the final competition. These successful competitors will be required to produce a plaster model of one-tenth scale, a plan and elevation on about 1½in. scale, a section at the same scale, a sheet of full-size details and a perspective view of the monument, together with a specification and detailed estimate of the cost, with indications of the materials to be employed. The total cost of the work should not exceed £10,000. Three prizes of £120, £80, and £40 will be awarded to the first three chosen designs in order of merit. A further sum of £80 will be distributed amongst those competitors whose work is judged to be of sufficient merit. The premiated designs will remain the property of the town of Lyons, with the right of intrusting the execution of the work to one of the successful competitors or to any other person who may be chosen.

An interesting experiment is being made for the wood paving of the Faubourg Montmartre. Six sorts of wood have been laid: the pine of Landes, which up to the present is generally employed at Paris; pitch pine, which is considered excellent as allowing a good footing for horses, owing to the gravel which is very easily forced into the wood; the karri, a kind of eucalyptus coming from Australia, very strong and of a bright-red colour. This wood, which appears to be the most suitable for wood-paving, is about twice as dense as the Landes pine; wear makes it smooth and bright, giving it the appearance of mahogany. A number of Paris streets have already been paved with this wood. It compares most favourably with the before-mentioned wood, and with the lime, teak, and Borneo wood which are also being tried in the Faubourg Montmartre.

There is a great deal of talk about piercing further roads through the Bois de Boulogne at Paris, and the construction of lines of tramways and electric or steam railways through the wood at different points. The controversy is over the question whether this fine wood—the holiday resort of Parisians, should be left in its present more or less wild state, or whether the making of roads and lines leading well into the thickest portions would be to the interest of the Parisian public. The Bois de Boulogne is the last remnant of the immense forest of Rouvray, which once extended far along the plains and hills bordering the Seine, and which, so the legend says, was the favourite hunting place of King Dagobert and his attendant, Saint Eloi. At the commencement of the 12th century it had already undergone a certain amount of destruction, and, changing its name, was called Bois de Saint-Cloud. In 1319, several pilgrims having erected near St. Cloud a small church similar to that existing at Boulogne-sur-Mer, the wood was called Bois de Notre-Dame-de-Boulogne, which became simplified into Bois de Boulogne. Setting out from the 13th century, most of the sovereigns and their followers established their residences in the Bois de Boulogne. The oldest of these residences was the Abbey of Longchamps, founded in 1256 by Isabelle of France, sister of Saint Louis, and inhabited later on by Philippe le Long, Blanche of France, and Jeanne of Navarre. This monastery, once a place of pilgrimage, became at length the place of festivities for the Court and town and the celebrated pilgrimage during Holy Week, which provoked so much scandal. In 1530 the Château de Madrid was built by Francis I., and was successively inhabited by the reigning monarchs from Henri II. to Louis XVI. Amongst other historical souvenirs of the Bois de Boulogne, may be mentioned the Château de la Muette, at Passy, the favourite residence of Louis XV., and of Marie Antoinette. Ranelagh was built by order of Marie Antoinette, after the model of the celebrated Chelsea Ranelagh. Under Louis XIV. the first rules and regulations for the proper preservation of this wood were edited; under Napoleon I. a great transformation took place: numerous roads and alleys were formed, a large quantity of new kinds of trees were added, and the body of forest guards, for looking after the proper keeping of the woods was organised. During the campaign of 1814-15 the wood suffered much devastation; under the Restoration the trees, roads, and alleys were restored, and, except for the short occupation by the enemy in 1870, causing a certain amount of destruction, remain at the present time as they then existed. It is probable that the Parisians will prefer to have their favourite holiday and Sunday resort left in its present rough state as regards certain portions, rather than see its wild beauty destroyed by noisy tram-lines and smoky railroads, despited the greater convenience which would thus be given for rapidly arriving at the places of amusement or wooded glens.

A great cry of alarm is being made over the historical monuments of Paris, which, it is said, are fast menaced with ruin or destruction for want of efforts for their preservation or restoration. M. Charles Normand, the general secretary of the Society for the Protection of Parisian Monuments, is of opinion that the cause is less on account of lack of money than on account of its bad employment. He says that portions of the various buildings or monuments threatened with ruin are completely renewed instead of being looked after and cared for progressively before any real deterioration becomes apparent. The former method, in his opinion, is most costly and dangerous, for there is nothing which destroys more effectually any masterpiece than its distortion by a too complete renewal. Besides, in the opinion of M. Normand, the Committee of Historical Monuments contains too many incompetent members, and is too partial for one epoch or another. In spite of the pressing demands of architects, this committee has abandoned the oldest church in Paris—Saint Pierre of Montmartre, erected on the site of a Roman building whose columns may still be seen in the nave of the existing church. The apse of Saint Martin des Champs, a superb Romanesque monument, is falling into ruins; the Hotel de Sens and that at Cluny are the only two buildings of the Middle Ages still existing at Paris; the loss of the remarkable Hotel de la Tremoille was due to the lack of zeal in a committee which might easily have saved it from destruction. On the other hand, M. Viollet-le-Duc, chief of the service of historical monuments, is of an entirely different opinion. He says that the reproach of incompetence can hardly hold good, the committee being formed of a large number of the best known architects and archæologists in the country. M. le Duc says further, that the total budget for the maintenance of all the numerous historical monuments in France is only just over £50,000. These funds are so small, that it is most necessary to act with the greatest circumspection, and employ the money only in cases where it is judged absolutely necessary. "At Paris it is a most difficult matter to find extra moneys for such purposes. The town very often does its own work of restoration, sometimes even without informing us of its doings; or, again, it often refuses, in exchange for the sum of money we offer to put at its disposal, to allow our architects to direct the work, or even to authorise its own architects to follow our advice. This love of independence in the matter of art and archæology is most prejudicial to the preservation and maintenance of our historical monuments, and it is thus that our masterpieces are distorted or ruined. The work at Saint Germain des Prés, at Saint Germain l'Auxerrois, at the Church of the Sorbonne, and at Saint Martin les Champs was done without our aid; that now being done at Saint Eustache is likewise undertaken by the town of Paris, then when certain difficulties arise they come to us to request our advice and money. At Saint Pierre de Montmartre a preliminary scheme of restoration was submitted by us to the town council; the town would, however, not share in the expense, and we are not rich enough to undertake the work. At Saint Julien le Pauvre, considered a unique example of Romanesque architecture, we were fortunate enough to be able to do the work of restoration without the help of the town of Paris. This year we are undertaking the work at the Saint Chapelle, additional work at Saint Julien le Pauvre, and that at the Cluny Museum. We were desirous of buying the Hotel de Sens, but the proprietor demanding £40,000 for its purchase, our budget being scarcely more than this sum, the town of Paris offering us no aid, we were obliged to give up the idea. If we do not accomplish all that we ought, we, at least, do all that we can." The reply of Viollet le Duc appears perfectly reasonable. It is evident that a lack of funds is a great drawback to the proper maintenance and restoration of the fine examples of ancient architecture which Paris still contains. It is to be hoped that the State and the authorities of the various towns containing examples of old work will decide to be more lavish in providing funds; otherwise the ravages of time and the exigencies of commerce will soon do much to rob France of her most interesting masterpieces.

The work of rebuilding and enlarging the Lyons Railway Station at Paris is now commenced. The first portion of the work consists in the enlarging of the central hall, which will now have a length of 720ft., formed of two bays of 140ft. span each. This work is being done under under the direction of the Paris-Lyons Railway Co. The train service will be in no wise interrupted during the whole course of construction.

The Service of Architecture for the Exposition of 1900 is preparing the programme of the competition for the two palaces of the Champs Elysées. It will be submitted to the town council early in October. The time allowed for the preparation of the drawings will probably be three months.

The Exhibition of Work, although opened on the 25th of last month, is only now complete as regards the installations and exhibits. The building section contains very interesting exhibits as well as plans, drawings, models, and details of work already executed or in course of construction. As soon as the installations are perfectly complete an account of the most interesting exhibits will be given.

The Union Centrale des Arts Decoratifs has lately formed a large committee chosen from the ranks of men most distinguished in the theory and practice of decorative art, in view of the important competitions to be organised for the Exposition of 1900. Each of the five sub-committee is preparing its special programme for each industry—wood, metal, glass, clay, paper, and tissues. Each competitor will be perfectly free to choose the object which he desires to send in as representing his special industry. This liberal system of competition appears to give much satisfaction to all interested.

The Musée Social, inaugurated a short time ago, is already doing much good work in the organisation of competitions and awards to workmen. Two missions have been organised for September and October next, one in England and the other in Germany. The first will study the labour question in Great Britain, and chiefly the organisation, working, and results of the system of trade unions; the second will study the question of socialism in Germany. The founder of the Musée is about to recompense with a life annuity of £8 each 25 deserving workmen. These will be chosen from among workmen of at least 60 years of age who should prove 30 years of employment in the same works, or justify exceptional services. Two competitions are opened, the first having as subject the origin of the participation of workmen and employés in the profits, its actual state, and the existing results, the advantages of this participation as regards the relations between employés and workmen, and as regards the proper remuneration of capital and work. The second competition concerns the co-operation of workmen, syndicates, and co-operative societies, of demand and supply, construction, economy, and credit. Writers of all nations are admitted to these competitions, the prizes for each are fixed at £1,000. The work should be written in French, and sent in to the offices of the society, 5, Rue Las-Cases, where all particulars may be obtained, before Dec. 31st, 1896, for the first competition, and Dec. 31st, 1897, for the second.

ARTHUR VYE PARMINTER.

CLASSIC DETAILS AND THEIR APPLICATION.[*]

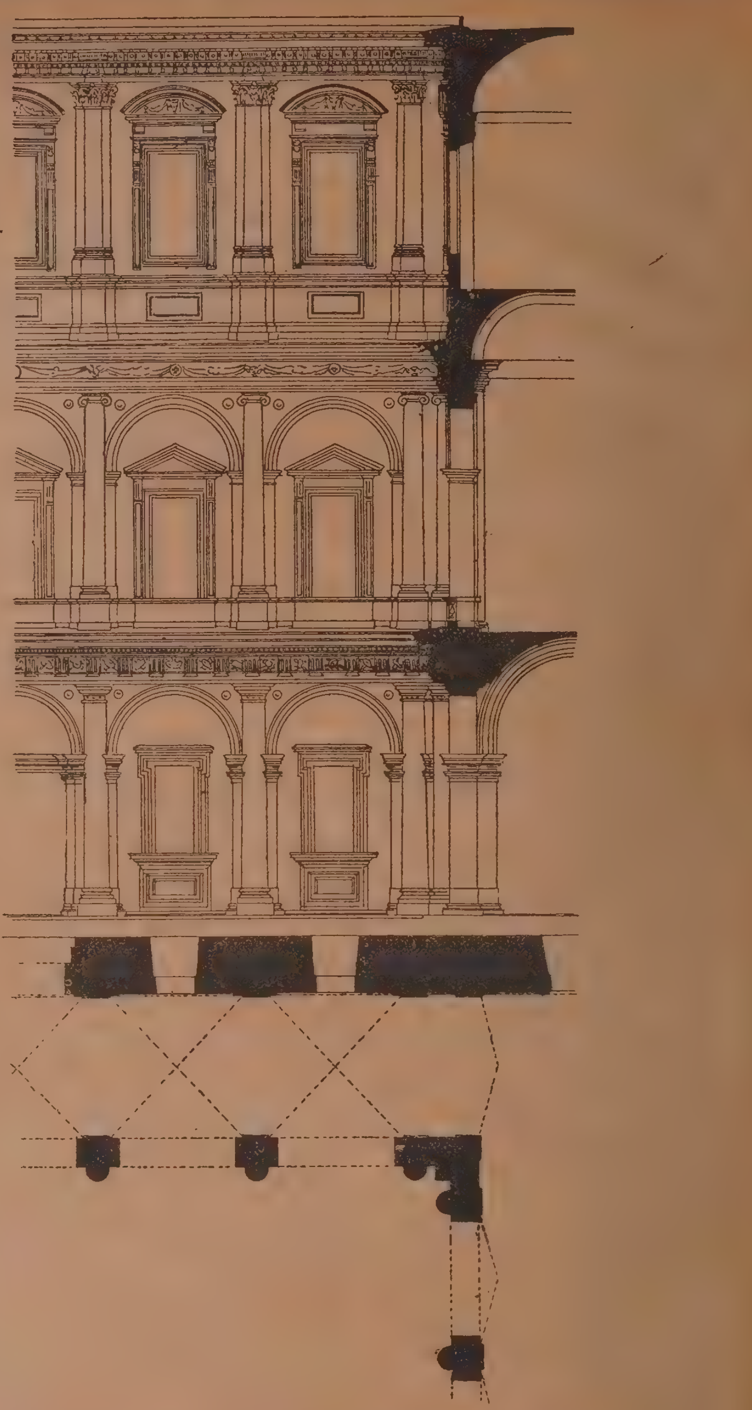
By G. A. T. MIDDLETON.

IX.—ITALIAN RENAISSANCE: SUPERIMPOSED ORDERS.

THE use of superimposed orders was so common in ancient Rome that it would naturally be looked for in the Renaissance period; but it does not seem to have become customary until a somewhat late period. Then, too, it occurs, as does all enrichment, in the courtyards and cloisters—the internal façades, as they may be called—before it does on the exteriors; and, in fact, superimposed orders are but rarely seen, externally at least, in the Renaissance work of Florence, and comparatively seldom at Rome, though their use is frequent enough in Venice and the neighbouring cities.

There are also two very different systems for their employment to be noticed. Bramante, and also the members of the Venetian School, seem to have understood that the superimposition of orders was permissible, and was always to be consistent, in so far that the Doric was to be the lower or most prominent, then the Ionic, and then the Corinthian; but they exercised freedom in treatment, dealing with them, as with all other features, as elements for use in building up a Renaissance design. On the other hand, some of the Roman architects, possibly over-influenced by the great examples of the Colisseum and Theatre of Marcellus close at hand, held to the ancient precedent with an almost excessive devotion.

A marked example of this method is the courtyard of the Farnese Palace at Rome, of which the general scheme was probably by San Gallo and the detail by Michael Angelo. The ancient precedent is followed here in the general outline, with the usual result of an absence of life; and if it had not been for the genius which introduced vigour and originality into the details, the whole effect would probably have been tame. It forms a sermon upon the unwisdom of following precedent too closely, when the original conditions have been changed; in this instance a design intended originally for a convex exterior has been employed for the flat side of a courtyard.



Courtyard of the Farnese Palace, Rome. By Michael Angelo and San Gallo.

Bramante had already treated the cloister of Sta. Maria Della Pace, at Rome, in a much more correct spirit, superimposing a Composite upon an Ionic order, both as pilasters of slight projection, as ornaments only, without having the slightest pretence to helping the construction, and introducing small Corinthian columns constructionally in the upper story in an original, subdued, and wholly artistic spirit.

Turning now to the employment of superimposed orders externally at Venice, we find a development from what had gone before in the immediate past, not a following of ancient precedent. In the Carnossa Palace at Verona is to be seen very much the same treatment as in Raffael's Cafforelli Palace—a rusticated lower story, with an order attached to the upper; the fact that the order is Corinthian, and that pilasters are used instead of columns, not seriously affecting the point at issue. The same architect, Michele San Micheli, who designed the Carnossa Palace, then develops his scheme, by the superposition of orders, into the Bevilacqua Palace at Verona, in a very simple way, and allowing himself entire freedom, produces a rich work of great beauty. The rusticated Doric pilasters applied to the face of the rusticated lower story, and the fluted (straight and spiral) Corinthian columns of the upper, are pure developments in a Renaissance spirit, while the deep balcony and the large use of sculpture are also new features, such as add richness to many buildings of the Venetian school.

Sansovino's Library at Venice is a combination of this natural development, and the close following of precedent evidenced at the Farnese Palace; for here are the orders superimposed in a very Roman manner, each strong and perfect according to the Roman standard; while the great use of sculpture, the use and coupling of the columns in the window jambs of the upper story, and the use of a balustrade above the crowning cornice, are all evidences that a real architect, and not a mere copyist, was at work. As a matter of fact, Sansovino occasionally carried his desire for novelty too far, being rather fond of employing

detached orders upon the face of his work, as if constructionally, but with no constructional function being apparent—or, rather, with the falseness of the device prominently displayed to even the most casual observer. The result in his hands was beautiful enough; but it was obtained by taking liberties, giving precedents for work on faulty lines which some of his followers, endowed with less skill than himself, adopted without achieving his success. It was, in fact, the first step towards a subsequent deterioration.

PROTECTION OF IRONWORK FROM FIRE.

WHEN it becomes necessary to observe that due and proper regard which should always be paid to æsthetic principles, the substitution of columns of wrought iron for those of cast iron is not always practicable. The latter material does not lend itself with the same ease and facility to the delicate mouldings, and often almost minute changes in form and dimensions required, as the former. This reason does not apply to examples of construction in which the columns and piers are all underground, or wholly concealed from view. Instances of the latter description are to be seen every day in the building of warehouses, business premises, shops, and even of dwelling-houses. It may be asked, Why in such instances is wrought iron employed—as it nearly invariably is—to the exclusion of its older rival? It is true that the cost of wrought iron and steel has of late years—especially that of steel—very considerably diminished. But so also has that of cast iron, and in reality the balance is pretty much what it ever was. On the score of mere cheapness, the advantage would still lie on the side of iron, and yet the stereotyped method employed in constructing the façade part of the carcase of a large building consists in using stone or brick piers and side walls carrying spans of wrought-iron or steel girders, which are subsequently completely hidden from sight by wooden or plaster coverings and decorations. It is not a question of cost, nor of strength, nor of appearance, since any amount of ornamentation can be applied indifferently to both materials. It becomes, in fact, a question of which material offers the best security for the safety of the public in the event of the occurrence of certain unforeseen contingencies. To one of these we intend to more particularly refer.

So far as the strength of iron columns and girders enters into consideration—that is, the adequacy of the resistance they oppose to the forces and stresses acting upon them—it is rare now that they evince signs of weakness, much less of failure. The days are gone by when the only conception of strength and resistance was embodied in the accompanying ideas of mass and weight. Under certain conditions, the old theory still holds good, but the conditions are somewhat exceptional. There is no doubt that to a certain extent—but to a certain extent only—the solid or massive style of construction was sufficient for its day. The semicircular, or nearly semicircular, arch of the Early Norman period is an example. It was speedily discovered that an increase in the span of the arch demanded a corresponding increase in the versed sine or rise, and to continue to construct stone, or even brick, arches of large span, with a rise equal to the semi-span, was practically an impossibility. Stone arches, whether of the semicircular form or of the segmental, elliptical, or any other of the numerous contours, such as ogee, trefoil, or cinquefoil, into which the original outlines have been contorted, enjoyed an immunity from a cause of destruction which has been frequently fatal to their slenderer and more modern metallic successors. It is alleged against cast iron, as one reason for its having to cede the *pas* to the wrought material, that it does not behave, when exposed to the action of a fierce conflagation, in so satisfactory a manner as the latter. So far as the actual effect of the flames is concerned, there is probably not much difference between them; but when water is poured in copious streams upon the red, and even white, hot metal, the wrought material possesses a decided superiority over the cast. Owing to its greater toughness, tenacity, and essentially fibrous nature, it will never break, although it may bend and deflect to a more or less serious degree. Cast-iron columns and girders under similar circumstances behave very differently. They are especially liable to become cracked, split, and fissured under the combined influence of the two elements to an extent which, if it does not entail the collapse of the building, very gravely imperils its safety and stability. It may be a matter of opinion whether wrought-iron columns and girders should be employed again in building construction after having been subjected to a great "fire"; but the same doubt hardly exists with respect to those of cast iron. These latter are seldom fit for much else except the melting-pot, after having undergone a similar fiery ordeal.

In order to ascertain the amount and nature of the protection which iron requires to obtain immunity from the action of a fierce fire, some very valuable and interesting experiments were recently undertaken by the engineer-in-chief to the city of Vienna. In addition to an investigation respecting the effect upon iron, the inquiry included in its scope the determination of the different resistances to fire which building materials generally were capable of affording. It will be admitted, as a rule, that this subject concerns the architect and builder more than the engineer, as the works of the former two are necessarily more exposed to the action of fire than those of the last mentioned. A railway bridge on fire, even when built wholly of timber, as in America, is a rare occurrence, and a similar spectacle in the case of an iron bridge still rarer. In the experiments referred to a space 12ft. by 8ft. by 12ft. in height was inclosed by a brick chamber. The inner surface of the walls of this chamber, or furnace, as it might be termed, was faced with stones and other materials used in ordinary building construction. In the middle of this furnace a built-up open iron pillar was erected, resembling, as will be described, one of the vertical braced struts or compression bars which are to be found in the majority of the large open-web girders and trusses of modern times. This pillar or vertical strut was composed of a pair of channel irons, 5½in. by 2½in., placed *dos-à-dos* about 3in. apart, and riveted together through their lateral projections or webs by small lattice-bars interlacing in the centre of the space, and thus forming a complete system of diagonal cross-bracing. In the interior of this hollow pillar were placed a dozen bars of cast alloys, each of which consisted of a different composition, and possessed its own point of fusion. These latter varied from, approximately, 160° Fahr. to 1,700° Fahr. The alloyed bars, which were intended for the purpose of testing, having been inserted in the core of the hollow vertical pillar, it was incased in an inclosure of brickwork. The brick casing was built in ordinary mortar, was 6in. in thickness, and assumed the form of a pier 12ft. in height by 1ft. 6in. square. Nothing now remained but to put on the roof, light the fire, and observe and record the results.

It was considered desirable for the full success of the experiment that the roof itself should also be, similarly to the wall, fireproof. Wrought-iron joists were therefore laid across the longer walls of the building, and upon them were placed tiles, the whole being flushed up with concrete. Omitting the description of the mechanical details, which are not necessary to the result at issue, it may be stated that by means of a properly adjusted lever a weight of 15 tons was imposed upon the vertical hollow pillar. Combustible materials were then heaped up uniformly over the whole area of the floor to a height of a little over a yard, and the fire briskly maintained at full blast for nearly three hours. It should be mentioned that a couple of flues had been inserted in the fireproof roof to assist in keeping up the combustion of the fuel. At the end of the three hours it was assumed that the fire had done its work, and the services of the other or extinguishing element were called into requisition. After the whole chamber had been thoroughly drenched with water, both inside and outside, the heat was nevertheless so great that all examination of its effect upon the contents had to be postponed for another twenty-four hours. It must be borne in mind that this experiment is one of a very crucial character, and far more severe in the influence exercised upon the different materials than what could possibly occur in an actual ordinary conflagration. Summing up, the walls were found to have fairly retained their original perpendicularity, and the brickwork was but very little injured. With respect to the first of these results, it may be pointed out that the height of the walls was comparatively insignificant. It is very doubtful whether, under somewhat similar conditions, the walls of the giant buildings of New York and Chicago, fifteen and sixteen stories high, would escape with the same impunity. The arrises of the brickwork in the square pier were chipped and disintegrated to a trifling extent, and a few of the roofing tiles cracked and split, as might be expected. All the various building stones lining the interior of the side walls suffered very considerably, and proved themselves quite unfit to be employed as fireproof building materials. The sufficiency or adequacy of the brick casing, although only 6in. in thickness, to withstand the intense heat was amply demonstrated by the fact that the iron pillar underwent not the slightest injury, remaining perfectly intact. An additional proof of the security of the protection was afforded by the circumstance that only one of the twelve bars of alloy evinced any signs of fusion, and that was the one which had the low melting point of 160° Fahr. On the other hand—and this is a result worth recording and noticing—it was shown most unmistakably that plastering or plaster-work of any description was utterly useless as a protector of iron, or, in fact, of any other work or material, against fire. It is a little curious that, although the brickwork stood so well, it was completely penetrated—that is, thoroughly wet through—by the water. It would be interesting to ascertain whether brickwork set in cement would behave in the same manner under the same conditions.

THE INSTITUTION OF JUNIOR ENGINEERS.

THE Belgian summer meeting of this Institution, which took place last week, passed off very successfully. Assembling at Harwich, the party, consisting of nearly sixty members, crossed by the G. E. Ry. s.s. *Ipswich*, and arrived at Antwerp on Saturday morning, 17th inst. Here they were welcomed by M. Royers, engineer-in-chief to the Municipality, who conducted them over the extensive docks, and explained the numerous features of interest in connection therewith. The Musée Plantin and the station of the Compagnie Hydro-Electrique Anversoise were also specially open for inspection.

On Monday the members proceeded to Ghent, where MM. Carel's engine works, M. Van Houtte's nursery gardens, and M. de Hemptinne's cotton spinning mills were seen, the respective proprietors showing the visitors round. In the evening Brussels was reached, and the central electric-light station there was visited, under the guidance of Mr. Phibbs.

Tuesday was left open, so as to afford the opportunity of visiting the various places of popular interest for which the city of Brussels is noted; in the afternoon most of the party made an excursion to the field of Waterloo. Leaving Brussels on Wednesday morning, the members arrived at Liège about noon, and were received by M. Gillon, President of the Association of Engineers from the University of Liège, and by M. Firkets, President of the Liège Section. The afternoon was devoted to visits of the Vieille Montagne Zinc Works, at Angleur, under the direction of M. Gillard, secretary of the company, and other gentlemen; and the St. Leonard Locomotive Works, where the chief engineer, M. Shoest, showed the members over. In the evening, at the Hotel de Suède, a banquet was given in honour of the Institution by the Liège section of the Association of Engineers from the University, M. Gillon presiding, faced by M. Firkets.

On Thursday, an excursion was made to Verviers, on the invitation of the Chamber of Commerce. Arriving at the Est Station, the president, M. Garot, M. Mullendorff, M. Soubre, secretary, and other gentlemen of the town, met the members, and, entering carriages, drove to the wool-washing, combing, and dyeing works of MM. Peltzer et Fils. The wool-card manufactory of M. Duesberg-Debrez was next visited, after which the party were entertained at luncheon at the Société de l'Harmonie, M. Garot presiding. The wool-spinning, weaving, and finishing works of MM. Peltzer were seen afterwards, and train was then taken for visiting, under the guidance of the engineer, M. Mahwood, the Gileppe reservoir, which supplies water to Verviers and Liége. In the evening, the Liège electric-lighting station was seen, Mr. Hickson conducting the members through it.

Friday's programme comprised a visit to the extensive works of the celebrated Society Cockerill, where the party were welcomed by M. Delloye Matthieu, chairman, and M. Kraft, chief engineer to the society. Luncheon was subsequently served, and in the afternoon the Val St. Lambert glass works were visited, with M. Duprez, general manager, as guide. In the evening, the summer dinner of the Institution was held in the Salle des Vitraux of the Hôtel Mohren, Liège, the chairman, Mr. H. J. Young, presiding. On Saturday, sectional visits were paid to the Small Arms Works, the Liège Electric Tramway Installation, the works of the Compagnie Internationale d'Electricité, the Liège gas-works, and M. Foulon's iron foundry. The party returned to England in the afternoon. At each place visited throughout the week, the Belgians were exceedingly cordial in their welcome, evoking from their visitors expressions of the liveliest appreciation.

COUNTY LUNATIC ASYLUMS.—XXVII.

By George H. Bibby, F.R.I.B.A.

MEDICAL STUDENTS' TRAINING WARDS.

WHILE the asylum system now existing shows a very great advance upon the condition of matters half a century since, yet it does not appear to have kept pace with the progress of medical science in other departments. For instance, high authorities upon the subject of the education of medical students have approved of the establishment of an asylum building which would practically combine with a hospital for the insane, special facilities for the education of resident and other medical students, giving them opportunities of studying the subject of insanity from the appearance of its earliest symptoms to its latest development.

The question as to whether hospitals for the insane should be maintained (with special facilities for students and lecturers upon the subject of insanity) has been recently a matter for considerable discussion. The general opinion appears to be strongly in favour of supplying further means for the education of medical students in a department of science that has been somewhat neglected. At present many medical men may be called upon to give certificates as to the sanity or insanity of persons, without perhaps having had any opportunities of much special instruction upon the subject; and Dr. Stephen Mackenzie has expressed the opinion that it is "very difficult for every hospital to be affiliated to some institution where men will get the information they want, and therefore it is important that the knowledge, which physicians connected with those hospitals can to a certain extent impart, should be supplemented by the more accurate knowledge and more complete experience which may be gained at institutions for the treatment of patients suffering from insanity."

Therefore buildings are admittedly requisite for the purpose of dealing with those classes of the insane who, while affording special subjects for study and investigation by medical men, would, if possible, be cured by the assistance of the resident staff, and who would, more or less, afford material upon which the lecturers on insanity would discourse to a *limited* number of students. It has been proposed by medical authorities that clinical assistants should be appointed in the proportion of one to every ten patients, to observe the cases and report to the physicians and surgeons (visiting or resident), these student-assistants being appointed for terms of three or six months, and occupying the period as a portion of the time allotted to their general medical training. By this arrangement the patients would probably benefit, and scientific research would be promoted.

The buildings intended to form a *hospital* for the treatment of insanity, with suitable provision also for lecturers and students, would obviously be far more conveniently situated in or near to a large town, so as to be easy of access to the medical profession, were it not for the difficulty in caring for patients in districts more or less thickly populated, and where exercise grounds would be limited in extent for economical reasons; but against the latter difficulty may be set the fact that a hospital asylum even in a town may be expected to be far more advantageous for the patients than the homes from which many of them are drawn.

Assuming that it be decided to add to a county asylum (situated within a reasonable distance of a large city) a block of buildings for the use of those who not only have the care of patients, but also the necessity of providing for the requirements of scientific inquiry, and for the study of insanity by the younger medical men and students, it would for some reasons be desirable that this special hospital-asylum should be near the blocks of buildings for recent cases.

The hospital-asylum, if connected with the main asylum and upon a full scale, might include provision for the following apartments, there being separate pavilions for male and female patients:—

Lecture-room, 35ft. by 20ft.
Lecturer's private room, 18ft. by 15ft.
Museum, 40ft. by 20ft.
Laboratory, 30ft. by 20ft.
Chambers for *five* resident medical students.
Administration buildings (exclusive of laundry, general stores, &c., included with main buildings of asylum).
One pavilion for male patients, with two day-rooms, dormitories, ten single rooms, and usual offices.
One pavilion for female patients, with similar accommodation.
Residences for medical officer in charge, and for attendants, matron, and nurses, &c.

The cost of an entirely detached hospital-asylum, whether erected in the town or in the suburbs, would necessarily be greatly in excess (per patient) beyond that incurred usually for either borough or county asylums, as many portions of the main asylum, including some of the administrative buildings and the chapel, could be jointly used. The following is an approximate estimate by Mr. Burford Rawlings, of the National Hospital for the Paralysed and Epileptic. These figures are only conjectural, and are for the cost of an *independent* institution for 100 patients; but they clearly show that the cost is expected to be much greater (probably double) than that incurred for ordinary asylum buildings.

The following estimate was given exclusive of site, and is the "approximate cost of erecting a hospital for the study and treatment of insanity, to contain 100 beds for patients, with a day-room attached to each dormitory, a sufficiency of isolated rooms for special cases, and needful accessories":—

	£	s.	d.
Building of, say, two pavilions of 50 beds each, an administrative block, lecture-room, and chapel ..	24,000	0	0
Engineering work, including hydraulic lifts for passengers and food, heating apparatus, baths, service of hot and cold water, &c.	2,500	0	0
Fittings for kitchen, dispensary, &c.	700	0	0
Architect's fee, at 5 per cent. on above items	1,360	0	0
Clerk of the works	250	0	0
Furniture and general equipment ..	2,690	0	0
	31,500	0	0

In this scheme no rooms are specially mentioned for pathological purposes, but these may be presumed to form a portion of the administrative buildings. What is now wanted by the medical superintendents of asylums, both here and abroad, is a greater means of promoting scientific research as to the causes and best modes of treatment of insanity, and for this purpose suitable buildings and equipments are greatly needed. It would appear desirable in some districts to erect one hospital-asylum to be worked in connection with two or more ordinary asylums, more especially if these be not very large ones, for by such an arrangement higher salaries could be paid to the lecturers and pathologists, and the services of highly accomplished men secured. With regard to the medical superintendent and assistants of most English, Irish, and Scotch asylums for pauper lunatics, their duties are already so varied beyond medical

duties, and include business transactions connected with the reception, retention, recovery, discharge, and removal, death, escape and recapture, mechanical restraint of patients, also duties concerned with the correspondence of patients, the admission of their visiting friends, and the preparation of numerous statistics, accounts, &c., that it would be difficult for them to give adequate time to their purely medical duties, much less find opportunities for lecturing for the benefit of students upon the subject of insanity, or for making pathological inquiries.

Laboratories appear to be provided to a very considerable extent in many asylums in Belgium, Denmark, France, Germany, Holland, Italy, Russia, Switzerland, and the United States of America, and particularly in Germany, where it appears to be a rare exception for an asylum to be without one or more laboratories. This is more than can be said for the asylums of this country. Possibly the medical superintendents of those countries may not be required to give so much attention to general adminstrative matters, and the preparation of statistics and reports, &c., and have therefore more time at their disposal for laboratory and pathological work. An asylum superintendent has stated that, in his opinion, "it is unquestionable that the study of insanity is one of the most abstruse and difficult—perhaps the most abstruse and difficult subject that can occupy the mind of man." If this be true, it would appear to be desirable that asylum superintendents should not so frequently unduly encroach upon the special province of the architects who may be engaged in adding some new annexe to their asylum buildings, or engaged upon the alteration of asylums which have ceased to be up to date; neither would they appear to have sufficient time at their disposal to interfere with the numerous details of construction, heating, ventilation, and engineering, which are surely more advantageously left to the discretion of capable engineers and architects who may have made these subjects their life-long study.

In confirmation of this, I venture to quote evidence given by Sir James Crichton Browne, the Lord Chancellor's Visitor in Lunacy, and the former superintendent of several asylums. He said: "As a matter of practical experience, the medical superintendents of England have found that the committees of magistrates, who are their masters, are very much better able to appreciate the way in which they carry on the farm and attend to the finances or the general administration of the establishment than the way in which they do their medical work. This latter the justices are scarcely capable of judging of, and it used to be not an uncommon thing in county asylums for a young medical assistant, fresh from the schools, to be put into one department and given entire charge of it, many hundreds of cases being put completely under his medical guidance, while his chief, the superintendent, devoted himself to *building* or farming, and sometimes did not visit the wards for long periods together. I remember a case in a large asylum in the North where a woman who had been in the asylum for *four months* asked, when the medical superintendent came into the ward, 'Who is that gentleman?' She was told he was the medical superintendent. 'Indeed!' she said, 'I thought he was the *architect;* he only comes in when the chimney smokes, or the walls want papering, or something of that kind.'"

To return to the subject of medical students' training wards in connection with hospital asylums. There can be but little doubt that better provision for the purpose of giving instruction on the subject of the treatment of the insane is much required, and that special buildings will be eventually added to the larger county asylums with this object; the asylum architect will probably have to arrange his plans upon a more costly basis than for other parts of the asylum—say, £300 per patient, instead of the £150 to £200, which appears to be a usual amount as matters exist.

Fewer ordinary attendants would probably be required on the *male side,* as if *resident* medical students were introduced, these might, to a moderate extent, occupy the position not only to their own advantage by reason of the opportunities of obtaining an intimate knowledge of questions connected with insanity, but also to the advantages likely to be enjoyed by patients brought into contact with persons of a higher education, and advanced considerably in their knowledge of medical and surgical matters.

It would almost appear that more attention is directed in some foreign countries than in England to the necessity for a full complement of buildings for the training of medical men to asylum work. Dr. Giandri, of the asylum at Cuneo in Italy, states that *all* Italian asylums have good laboratory accommodation, and I have before me a lengthy list of asylums in other European countries with similar provision, with elaborate equipments and great facilities for scientific investigations into the causes of insanity.

(*To be continued.*)

HOUSE SANITATION.

IN an elaborate paper on "Origins of Sanitation," by Dr. J. Spottiswoode Cameron, medical officer of health to the city of Leeds, &c., delivered at the recent Congress of the British Institute of Public Health at Hull, the author goes back to the earlier conditions of sanitation and the prevention of disease. Remedial measures were at one time regarded as the main source. Even pathology was looked upon mainly as morbid anatomy—the classification of disease; but after a time medicine began to look "rather to the causing than to the resulting factors as the basis of classification." Dr. Cameron shows that, though the countryman might have an immense advantage over the denizen of the town, he was not free from various complaints, such as ague from his undrained land, outbreaks of fever from polluted water, and many other things. It was in the towns that the necessity of sanitation was first recognised. A class of maladies, such as relapsing fever, typhus fever, and small-pox, flourished best in crowded neighbourhoods. Overcrowding and foul air, polluted drinking water, were conditions favourable to disease other than zymotic. Speaking more particularly of accumulations of spent matters and house drainage, the author referred to the old-fashioned cesspool as a source of danger. "Nor was the danger greatly, if at all, lessened when the idea was suggested of placing traps in the course of drains to intercept effluvia generated in the sewer. These traps, it was soon found, were themselves effluvium producers close at hand, and a system of relieving all pressure in our drains, and disconnecting all house wastes from them, as well as of rapidly removing all solid accumulations, came to be regarded as essential to the well-being of a community." The separation of the sick in properly equipped hospitals and the notification of the existence of communicable diseases soon followed. After sketching the progress in sanitary legislation, the mapping out of the country into districts for health purposes, the obstruction offered by members of local boards, the employment of inspectors, and the desirability of a systematic examination of districts imposed by the Local Government Board, Dr. Cameron speaks of the importance of the Notification Act, which enables medical officers to give notice to the authorities in case of any communicable disease. This Act has enabled many serious sanitary defects to be discovered, and the author mentions that in one town every house is systematically examined; the number of occupants, of rooms, means of ventilating them, the water supply, drainage, &c., are all inquired into and tabulated, and he asserts that, without claiming the whole or chief part of the health improvement to be due to such examination, the yearly death-rate, which had averaged for the five years preceding this house-to-house visitation 22·3, has averaged during the last five years only 18 6, an improvement of more than 10 per cent. He also dwells on the fact that many new houses built under by-laws and inspected are yet faulty. In some cases, houses are found which still have connection with the sewer, even when every waste-pipe is supposed to be cut off from the sewer. A strong-smelling chemical introduced into the sewer penetrated one house of a row of new houses built under modern by-laws and inspected. But thousands of our houses have wastes which are not disconnected with the sewer. In a recent examination in the outskirts of a large town of recent erection, two-thirds had their wastes cut off and the other third not, and he found that the smell of a chemical entered the house through the drains in 18 per cent. of the former and in 60 per cent. of the latter. These facts all indicate—as he pointed out—that even modern by-laws, carefully carried out under able inspectors, will not necessarily guarantee, a few years later, the healthiness of a house.

SEWAGE DISPOSAL IN FRANCE.

THIS subject is now receiving some attention in France. Last year, at the Boulogne Exhibition, M. Howatson showed a small installation in demonstration of the efficiency of the ferozone-polarite system of sewage treatment. Two commissioners, MM. Genis and Rebouffel, were appointed to visit England to see the process in question in operation, and also other processes of sewage treatment. In the course of their visit, amongst other places, they inspected Royton, Hyde, and Huddersfield, seeing the International process at work. They also visited Manchester, Salford, Sheffield, Lincoln—(where they were received by the chairman of the sewage committee and the city engineer, Mr. McBrair, who explained that though the sewage farm at Lincoln was, by nature of soil, arrangement of filter areas, and size of tanks, theoretically more than sufficient for the treatment of a much larger place than Lincoln, the actual result was that the Lincoln sewage farm, like so many others, was a failure, and they were under threats of an injunction; in order to secure an efficient system the Lincoln Corporation were then engaged putting down polarite filters)—Birmingham, and, finally, Crossness. The result of this visit was evidenced by the Award d'Honnour of the Boulogne Commission.

As a sequel to this demonstration at Boulogne and the report of the distinguished engineers who acted as commissioners, the municipal council of Rouen, by a vote of 22 as against 2, have decided in favour of a scheme submitted by M. Howatson, C.E., on lines very similar to those adopted at Huddersfield—viz., precipitation by ferozone and filtration through polarite; but before carrying out this, it was decided to visit England.

In accordance with this decision the Mayor of Rouen (M. Laurent) and a numerous deputation reached England, and on Monday, the 19th inst., commenced their tour of inspection. In the morning they visited the Royton sewage works, where they were received by the chairman of the council, Mr. Walter Evans, J.P., and the clerk, Mr. Bleasdale. During this visit full details of the process were given by the chairman and by Mr. T. S. McCallum, C.E., Manchester, the engineer of the scheme.

The deputation were evidently impressed by the purification effected by the ferozone and polarite. The special method of cleansing the polarite filters by means of the "upward wash" was demonstrated. After lunch at the Railway Hotel, Royton, the mayor's party proceeded to Chorley to inspect the extensive new works designed by the borough engineer, Mr. Leigh, C.E., for the treatment of the sewage of Chorley by the International process. The chairman of the sewage committee, Mr. Alderman Hibbert, J.P., and the vice-chairman, Mr. Councillor Stones, received the distinguished visitors on arrival at the Chorley station, and thence drove them to the sewage works, where a close inspection of the various details was made, including a visit to the Chorley sewage farm, where the mayor's party had ample demonstration in favour of the treatment of sewage other than by sewage farms. Alderman Hibbert, at the conclusion of the visit of inspection, invited his visitors to join him in drinking the health of the President of the French Republic, in response to which the mayor, M. Laurent, proposed that of Her Majesty the Queen. Ere leaving the works, the Mayor of Chorley invited the deputation to visit him at the Town-hall, which they did after visiting the Chorley fire station *en route*, where the honorary captain of the brigade, Alderman Hibbert, explained the arrangements, concluding by having the horses put to the engine. Ere leaving the Town-hall, M. Laurent, the Mayor of Rouen, speaking on behalf of himself and the deputation, expressed their profound appreciation of the arrangement shown to them, and of the hospitality extended to them, inviting the mayor and the chairman to visit the forthcoming Rouen Exhibition as his guests. On Tuesday, the 20th inst., the deputation visited the Wigan sewage farm, where they were received by the mayor and other gentlemen of the corporation. After a careful inspection of the various parts, they had luncheon with the mayor, and left for Huddersfield, reaching that town on the evening of the 20th. During their stay in Huddersfield they were the guests of the mayor. The borough engineer, Mr. R. S. Dugdale, C.E., met the deputation on Wednesday morning, and conducted them to the sewage disposal works at Deighton, where they were received by the chairman, Alderman Jessop, and Alderman Walker. The mayor was detained by the Licensing Sessions, and so deputed the chairman to welcome M. Laurent and his colleagues in his name. The Huddersfield sewage works, designed and carried out under the direction of Mr. Dugdale, are well calculated to impress the visitor, alike from beauty of situation and arrangement of works, and from the admirable results obtained. As may be well imagined, the sewage of Huddersfield, receiving the refuse liquors of so many dye-works, &c., is very foul, and yet, after precipitation by ferozone and subsequent filtration through polarite, an effluent is obtained of such a nature as induced some of the deputation to taste it! In the course of their visit they were able to see a tank fitted with the Candy patent arrangement for the automatic removal of the sludge whilst the tank is working on the continuous flow. Ere leaving the works, M. Howatson was satisfied with the approval expressed by the various members, and ere long Rouen may have as efficient a sewage purification works and on the same lines as the Huddersfield works. Subsequently the delegates were driven to the Town-hall, and cordially welcomed by the Mayor of Huddersfield, by whom they were entertained to luncheon, along with several members of the council.

ARTISANS' DWELLINGS IN LIVERPOOL.

THE Corporation of Liverpool have under consideration a recommendation from their Artisans' Dwellings Committee that the provisions of Part III. of the Housing of the Working Classes Act, 1890, shall be adopted. The committee report that the Liverpool Corporation have erected the Victoria-square Dwellings, which were opened in 1885, and the Juvenal Dwellings, some of which were opened in 1888, and the remainder in 1890. The whole accommodation thus provided consists of 371 dwellings, of which 66 are single rooms, letting at from 2s. to 2s. 9d. per week; 217 are of two rooms, letting at from 3s. 9d. to 5s. per week; and 88 are of three rooms, letting at 5s. and 5s. 6d. per week. Gas is included in the rents of the Victoria-square Dwellings, and in a portion of the Juvenal Dwellings. The average number of unoccupied dwellings is about eight. For 1894, the Victoria Dwellings returned an income at the rate of £2 8s. 4d. per cent. upon the cost, including the value of the land estimated at 22s. 6d. per yard. The Juvenal Dwellings returned an income for that year of £3 8s. 2d. per cent. upon the cost, the value of the land being estimated at 24s. per yard. Indirectly the Corporation have been the means of housing the working classes by selling land which came into their hands through the operations of the committee, to builders for the erection of small self-contained cottages, of which no less than 627 have been erected since 1889. Most of these consist of four rooms, 579 of such having been built. Of these four are letting at 4s. per week, one at 4s. 9d., 21 at 5s., 251 at 5s. 6d., 110 at 5s. 9d., 185 at 6s., and seven at 6s. 6d., the average rent being about 5s. 8d. per week. In addition to these, 27 three-roomed dwellings have been erected, letting at from 4s. 6d. to 5s. 6d. per week, 12 five-roomed cottages letting at 7s. and 7s. 6d. per week, five six-roomed cottages letting at 7s. and 7s. 6d. per week, and four houses let with shops. Land has also been sold in Alexander Pope-street, Chisenhale-street, and Fisher-street, upon which 17 more cottage houses are to be built. Nearly all the cottages are let. A sub-committee are, however, of opinion that the results of the practice of selling vacant sites to builders for the erection thereon of cottages for the labouring classes are not entirely satisfactory, from the point of view of providing accommodation for the class of people accustomed to live in court houses, the houses erected being let at rentals too high for these persons to pay. The usual rent of a court house is from 2s. 6d. to 3s. per week, and of those fronting streets, and with their backs to the courts, from 3s. 6d. to 4s. per week. The sub-committee, therefore, recommend that the corporation should retain some sites in their own hands when they become vacant, and erect thereon suitable tenement dwellings or cottages to produce such low rentals as will give a fair return to the corporation upon the cost of the buildings and the value of the land, and provide a sinking fund for the repayment of the moneys borrowed, the value of the land being taken at the price it would fetch if sold to builders of cottage property. The sub-committee have had submitted to them by the city engineer and deputy surveyor several plans of houses, most of which possess many excellent characteristics; but it is impossible to make a definite selection until the extent and size of the available plots of land are known. With regard to the powers which the corporation have for the erection of houses, the Liverpool Sanitary Amendment Act, 1864, does not empower the corporation to erect houses on the sites of demolished premises, but that such powers can be obtained by the council adopting Part III. of the Housing of the Working Classes Act, 1890, relating to Working Class Lodging Houses. While it is desirable that the persons displaced should be re-housed, as soon as possible, in sanitary dwellings erected upon the sites of the houses demolished or adjacent thereto, owing to the crowded state of the land upon which the insanitary houses stand, it is quite impossible to provide upon any given site accommodation for the same number of persons displaced therefrom, having regard to the due requirements for light and air, as this class of dwelling should not exceed three stories in height.

CHIPS.

The first school erected by the Lancaster School Board was opened by the mayor, who is chairman of the board, on the 17th inst. This comprises the infants' portion only for upwards of 300 children. The entire school when completed will give accommodation for 1,000 children. The school has been built by local contractors from the design and under the superintendence of Mr. Robert Walker, F.R.I.B.A., architect, Windermere, and Church-street, Lancaster, whose plans were selected in public competition.

The new hospital, Pittenween, Fife, is being warmed and ventilated by means of Shorland's patent Manchester grates, the same being supplied by Messrs. E. H. Shorland and Brother, of Manchester.

The Stratford-on-Avon Rural District Council have instructed Mr. J. E. Willcox, C.E., of Birmingham, to submit schemes of water supply for the parishes of Alveston, Tiddington, and Moreton Morrell within their district. The council have also decided that the whole of the house drainage works in connection with the new sewerage scheme of Henley-in-Arden shall be carried out by the contractor to the works, Mr. Griffin, of Henley-in-Arden, under the supervision of the engineer, Mr. Willcox.

Archbishop Croke has recently presented a very fine chiming clock to Thurles Cathedral, Ireland, which strikes the hours on a 35cwt. bell, chimes the Cambridge quarters, and shows time on three large dials. The whole of the work has been carried out by John Smith and Sons, Midland Clock Works, Derby.

The authorities of the British Museum have, for financial reasons, been unable to purchase for the nation the collection of upwards of a thousand old Japanese colour prints made by Professor William Anderson during his long stay in Japan. The collection, which contains a series illustrative of the handblock colour printing of the old Japanese artists from the earliest date up to the middle of the present century, has been in the hands of the authorities of the Museum for nearly two years, but has now been acquired by Mr. Ernest Hart, who intends, after the collection has been catalogued and classified, to place it in one of the national museums.

OLD HOUSES, FRIAR-STREET, WORCESTER.—COUNTY HOUSE AT BEDFORD.—NEW MARGARINE WORKS, SOUTHALL.—CATHOLIC CHURCH AND PRESBYTERY AT HEBDEN BRIDGE—DESIGN FOR A WATERGATE.

Our Illustrations.

OLD HOUSES, WORCESTER.

Friar-street, or Grey Friars, has remained without change in name, which it derived from the Franciscan Grey Friars, who had a house on the site of the old city gaol. Hadington informs us that there was a gate opening from the friary into the city, and that without the city wall, which passed near there, was the church of St. Lawrence, and within the wall was St. Lawrence-lane, which, between Needlers-street (Pump-street) and Lich-street, made a passage into High-street. That lane is not in existence, nor any memory of its whereabouts. The timber house to the right of the picture is one of the most remarkable still standing in the city of Worcester. The drawing which we reproduce to-day is by Mr. H. P. Weaver, and for which he was awarded a National prize by the Science and Art Department last year.

COUNTRY HOUSE AT BEDFORD.

On May 10th we illustrated the hall of this house, from Messrs. Scott and Morris's drawing at this year's Royal Academy. To-day we give an interior of the dining-room and two external views, showing the garden front and entrance side of the same building. The architects have furnished us with no precise details of the work, but we understand that an endeavour has been made to realise modern convenience in conjunction with an Old English character and simplicity of treatment. The plan would have explained the interior contrivances more advantageously; but an objection to its publication prevented its appearing with these views. They show sufficient to enable one to estimate the eminently picturesque character of the work, though the wooden balustrade on the garden front to the eaves hardly enhances the effect.

NEW MARGARINE WORKS, SOUTHALL, MIDDLESEX.

The above works have been erected for Mr. Otto Mönsted on a site adjoining Southall Railway Station. The Great Western Railway runs past the land, from which there is a private siding to the works. As another means of communication, a new road has been formed from the premises to the main road. On the north side of this road, at the entrance to the works proper, are arranged the offices, and on the south side the dining or recreation hall. The offices have been carried out in the Renaissance style, freely treated, and are built of red Ruabon bricks, the ornamental portion being in pink terracotta from the works of Messrs. Doulton and Co., of Lambeth, the whole being roofed in with green Westmoreland slates. Inside this building there is a general office 55ft. long by 25ft. 6in. wide, capable of accommodating sixty clerks, along the west side of which are arranged manager's, type-writers', and sale manager's offices and laboratories, &c., the entrance consisting of an inquiry hall, conveniently arranged for the general offices, and manager's private and cashier's offices. A corridor connects this part of the building with the works. On the south side of the road is situate a room 70ft. long by 24ft. wide, to be used as a dining and recreation hall, and for the purpose of entertainments, &c. On the easterly side of this are arranged the lavatories, timekeeper's office, and spacious kitchen for the cooking of the food, which is done by electricity. This building is carried out in a treatment of the Jacobean style, the base being built of red bricks with pink terracotta dressings, the walls of rough cast, with the gables and friezes modelled in Parian cement from the architect's design by Messrs. Hammond and Sons, artistic modellers, of Manchester, the windows, cornices, and ornamental woodwork being of oak, the whole roofed-in with red Ruabon tiles. Between these two buildings are situated wrought-iron gates, forming the entrance to the works. These and all the ornamental ironwork generally have been executed by Messrs. J. Jones and Sons, art metal-workers, Manchester. Inside these gates, and on the westerly side of the works, is the principal entrance leading into the main workroom, which is 148ft. in length by 100ft. wide, round which are situated the various workshops, store-rooms, milk-rooms, shipping-rooms, &c. On the south-easterly side is situated the engine-hall, which is 92ft. in length by 80ft. in width, roofed-in in two light spans and lighted from the top, close to which are situated the boiler-house, blacksmith's shop, machine-repairing shop, &c., loading dock and joiner's shop, which is 100ft. by 60ft., and a chimney 180ft. high. The works generally are carried out in a style similar to the offices, but plainer in character. The materials used are yellow stock-brick facings for the walls, with dressings and bands of red bricks, with red terracotta for the gables and doors. The whole of the works are roofed-in with blue slates, and a north roof-light is provided to all the rooms. Ample means of ventilation have been provided for all rooms. A conspicuous feature in the works is the tower rising from near the centre of the buildings, in which is placed an elevator for the various floors. The whole of the general works, offices, and dining-hall, together with the new road, &c., have been carried out by Messrs. A. and B. Hanson, builders, of Southall; the chimney and work connected with the boilers, &c., by Messrs. Warrington and Sons, of Hyde, Manchester; the whole of the concrete work and fireproof floors throughout, together with the constructional ironwork, by Messrs. Homan and Rodgers, of London and Manchester; the mosaic tiling, &c., in engine-hall, office-entrance, lavatories, &c., by Messrs. J. and H. Patteson, Manchester. The clerk of the works was Mr. William McMillan, and the architects were Messrs. Bird and Whittenbury, Manchester.

CHURCH AND PRESBYTERY, HEBDEN BRIDGE.

This group of village buildings at Fairfield, Hebden Bridge, is now in course of erection. The chapel accommodates 400 persons. The walls are of random blocked insides, with local stone dressings. The plan shows the arrangements and connection between the priest's house and the sacristy, under which is a boys' vestry. Messrs. Walsh and Wrigley are the architects.

DESIGN FOR A WATER GATE.

This design, which was executed in the Royal Academy School, and sent in for the lower school premium, 1894, was set as a subject by Mr. T. G. Jackson, A.R.A. The fundamental idea of the design is not only to give it solidity for the purpose it is meant for, but to give it simplicity, as well as a decorative effect. The room placed over the gate, and which leads off from the terrace, is an essential item; it not only serves for the accommodation of guests, but could with advantage be used in cases of accident. The medallions hung round the frieze, and placed on all sides, together with the lower frieze, are intended not only to enrich, but to give the building a sculptural as well as an emblematical feeling.

G. J. J. Lacy.

◆

The market committee of the Edinburgh Town Council have recommended the acceptance of an offer for heating apparatus for the Corn Market amounting to between £600 and £700, and an offer for carrying out additions and alterations to the slaughter-house amounting to about £2,000.

COMPETITIONS.

Newcastle-on-Tyne.—A selection has just been made from the plans for the proposed new building for the Newcastle Young Men's Christian Association. Three sets of plans had been sent in for competition; and the committee, after consultation with Mr. G. G. Hoskins, F.R.I.B.A., of Darlington, as specialist, have selected those tendered by Mr. J. W. Taylor, F.R.I.B.A., F.S.I., Westgate-road, Newcastle. The site is that occupied by the existing building in Blackett-street, with additional space which has recently been acquired. According to the selected design, there will be a basement and three floors above. The basement will be devoted to a café, bicycle stable, ventilating machinery, and w.c.'s. On the ground floor there will be six or seven shops. The floors of the shops will be level with the pavement, with a drop to suit the fall of any of the street levels. The principal entrance to the Y.M.C.A. rooms is in the centre of the façade in Blackett-street, and is 13ft. wide. The vestibule has double swing doors with glazed upper panels. Inside, the hall is divided into arched bays with panelled ceilings. Under the stair-landing provision has been made for a bicycle stable, with stands for 36 machines. The porter's room is situated at the side of the stairs facing the vestibule, so that that official can command the entrance to the rooms, bicycle stable, and the ground floor, and the heating chamber in the basement. As it is intended to let off the large hall, a separate entrance has been given from Blackett-street, with wide staircase and ticket lobby, and also back entrances from High Friar-street, which could be used for exit only if thought desirable. A separate staircase is also continued to the gallery. The first floor will contain a reception room, buffet, secretary's offices, lavatories and w.c.'s, cloakroom, Bible-class leader's office, reading-room, amusement-room, and hall. In the hall sitting accommodation is provided for 700 persons, including platform and gallery. On the second floor are a committee-room, young men's parlour, honorary secretary's room, small hall, ante-room, cloak-rooms for ladies and gentlemen, kitchen, and scullery. The chief feature of the third floor is a gymnasium over the large hall, a space of 12in. being left between the floor and the ceiling. On the same floor are two dressing-rooms, photographic dark-room, printing-room, and class-rooms. The elevations fronting the Monument and Blackett-street will be of polished Kenton stone, and the back wall facing into High Friar-street of glazed bricks and Kenton stone dressings. The style is English Renaissance of simple treatment, and unnecessary ornamentation has been avoided. The total cost is estimated at £16,500.

◆

CHIPS.

The corporation of Cape Town have ordered a plant for producing electrolised sea water, with a view to the Hermite process being applied to the sanitation of Cape Town.

At the last meeting of the Leeds City Council the Markets Committee asked for leave to advertise for designs for the reconstruction and extension of the Kirkgate covered and open markets. The matter was referred back to the committee for further consideration, and the committee met on Tuesday, and discussed the question for nearly three hours. It was resolved to instruct the city engineer to prepare a rough sketch plan of the proposed reconstruction and extension. It was also decided that the committee should visit the markets at Halifax, Newcastle-on-Tyne, and Carlisle.

At the half-yearly meeting of the Croydon Tramways Company held on Tuesday, the chairman reported that the Board of Trade had granted a renewal of the company's powers for a further period of a year, to enable them to complete the extension to Norbury, and when completed they would have a continuous line of tramway of about 13 miles in length, stretching from Westminster and Blackfriars Bridges to South Croydon.

The present means by which female witnesses attending the Law Courts can gain access to the rooms set apart for their use below the court corridor having been found inconvenient and difficult to find, the first of four proposed new openings from the court corridor to these rooms is now in course of construction, and will be ready for use when Courts reassemble in October next. This new opening, which is situated between Queen's Bench Court IX. and Probate Court I., has been effected by cutting an archway through the solid masonry of the wall of the court floor, thereby giving direct access to the rooms below.

Building Intelligence.

Douglas, I.M.—At Douglas, on Friday, the Lieutenant-Governor of the Isle of Man, Sir Joseph West Ridgeway, laid the foundation-stone of a new church for the parish of St. Matthew, in which parish is situated the oldest and most densely populuted district of Douglas. The new church will take the place of a commonplace building in Douglas Market-place. The old church has undying associations with the great Bishop Wilson, but it is rapidly falling into decay, and is inadequate in accommodation for the requirements of the parish; also it stands in the Market-place, which requires enlargement, and its fabric and site have been secured by the Douglas Town Commissioners, whose object is to demolish the church and thus increase the market space. The new site is at the corner of North Quay and Ridgeway-street. The church will be built from designs by Mr. J. L. Pearson, R.A., at an estimated cost of £8,000, and the sum of £1,845 is required to pay for the present section of the undertaking.

Hull.—St. Wilfrid's Roman Catholic Church, which is being erected on the Boulevard, Hessle-road, has been designed in the Early Decorated style, and will consist of nave, 76ft. long by 22ft. wide, with north and south aisles, 10ft. 6in. wide. At the east end of each aisle is an octagonal-ended side chapel, 22ft. long by 14ft. 6in. wide, the roof of which will be groined. One chapel is to be dedicated to the Blessed Virgin, and the other to the Sacred Heart. The aisles will be lighted by ten large three-light traceried windows, the clerestory of the nave by the same number, but rather less in size. The sanctuary will have four lofty two-light traceried windows, whilst the roof over the sacrarium will be so groined as to suit colour decoration in the future. The nave is divided on either side from the aisles by arcades of five bays, with moulded arches resting on clusters of polished red granite shafts, with moulded bases and carved capitals. The choir gallery is at the west end, above the main entrances, with an organ chamber and belfry at the side. There is a large working sacristy, with heating vault below, from which it is proposed to warm the church with piping on the high-pressure system. The accommodation provides for about 600 adults, and the contract for the building has been let to Messrs. Colley and Levitt for the sum of £2,895. The walling will be of red bricks with stone dressings. The church has been designed by and will be carried out under the superintendence of Messrs. Smith, Brodrick, and Lowther, architects, of Hull. The foundation-stone will be laid by the Right Rev. Dr. Lacy, Bishop of Middlesbrough, to-morrow (Saturday).

Leeds.—The new baths, erected by the Leeds Corporation in Union-street, were opened on Saturday evening. The building is situated in the midst of a densely-populated neighbourhood, upon the site of the old "midden." In construction and design the baths are almost a replica of those recently provided by the Corporation in Kirkstall-road, the architect being the same—Mr. W. Hanstock, of Batley. The interior fittings are practically identical. The water area in the first-class bath is 60ft. by 24ft., and in the second-class bath 75ft. by 30ft. There are in the first-class room the same marble-lined dressing-boxes on one side of the bath, and in the second-class the same open boxes, slate-lined, all round, forming an arcade, which supports a gallery, for the convenience of spectators. A row of vapour, needle, and slipper baths combined is provided in second-class department. A laundry also forms a feature of the institution, which has cost £7,000. Mr. Ainsley was the clerk of the works. Five sets of public baths are being provided in the city at the total cost of £50,000, the Union-street group being the second of the series.

Port Elizabeth, S.A.—The collegiate church of St. Mary, Port Elizabeth, is the oldest parish church in the eastern province. The foundation-stone was laid in 1825, and the building was open for Divine service a couple of years before the completion of St. George's Cathedral, Cape Town. Alterations and enlargements of the structure were completed in 1842. The tower was built in 1849, and since then many alterations and improvements had been effected, notably the reredos by Norman Shaw, R.A., and east windows, which were erected in 1880. The disastrous fire of March 9th totally destroyed the reredos, windows, and organ, and the building was completely gutted. The bare walls alone remained, and fortunately were uninjured. The difficult problem of the restoration of the bare walls was placed in the hands of Mr. Sydney Stent, of Cape Town. Mr. Stent's plans have been approved by St. Mary's Vestry, and have been on view in Port Elizabeth. The building and fittings were insured for £6,000. Mr. Stent's plans, include raising the walls 4ft., doubling the height of the tower, extending the chancel to a height of 58ft., and building an organ-chamber, cloisters, and new vestries. The lowest tender amounted to £8,600, and the work of restoration has begun. The memorial stone of the new portion of St. Mary's chancel will be laid with Masonic honours by Dr. C. J. Egan, the District Grand Master of the Eastern Division, on September 11. The Right Hon. Cecil Rhodes, the Premier, has headed the subscription list with a donation of £250, which is an encouragement that the remaining deficit of £3,000 may be speedily raised.

Royalty Theatre.—This theatre has been entirely reconstructed and redecorated, and the numerous alterations required by the London County Council have been carried out in their entirety. The seating capacity has been largely increased, and the whole of the ornamental portions have been removed and entirely new decorations of a novel character have supplanted the old. The system of colouring adopted for the auditorium is entirely in autumn tones, varying from the palest primrose to a deep copper bronze, the hangings being an amber brocade and bronze plush. An asbestos fireproof curtain has also been executed, and is so arranged as to be used in place of the old green baize, while a new act-drop has been painted in imitation of tapestry by Mr. Henry Emden. The theatre has also been entirely refurnished. The whole of the house is lighted by electricity, while a new stage has been constructed. Mr. Walter Emden, L.C.C., is the architect for the work. The carton pierre decorations are executed by Messrs. George Jackson and Co., the painting by Messrs. Campbell, Smith, and Co. The general contractor was Mr. Roffey, of Putney.

Rugeley.—A vestry meeting was held at the town hall on Tuesday week, for the purpose of considering the proposal to erect a new parish church. Plans were submitted of a church to be erected on the site of the present building. The tower would remain practically untouched, as well as the old chancel, while the old nave and north aisle would be rebuilt, and on the south side a new and spacious nave and chancel, with south aisle, organ chamber, shallow transept, and porch would be added. The proposed length is 110ft., and the width into the transept 79ft. The cost was estimated at between £8,000 and £9,000. After some discussion, the motion to proceed with the scheme was carried with only two or three dissentients. About £2,300 was promised towards the rebuilding.

St. Mary-le-Bow.—During the past month Wren's church of St. Mary-le-Bow, Cheapside, has been redecorated, and cleaned and repaired at considerable cost. The repairs, which have been executed by Messrs. Campbell, Smith, and Co., comprise no structural alterations; but an improved system of ventilation has been introduced. The old ventilators were almost useless, and four large hopper ventilators have been placed in the clerestory windows. Ventilators have also been fixed in the porch. The scheme of colouring consists of two tints of cream and cinnamon. The panels of the ceiling have been painted a strong buff, and the enrichments are in duck-egg green. Stronger tints of cream have been used for the walls and arches, and the large columns are painted a dull low-toned red. The church and ornaments have been generally cleaned and renovated; the reredos and old iron standards have been repainted, and all the old oak has been cleaned and varnished. Reopening services will be held on Sunday next.

Stoke Prior.—The church of St. Michael, Stoke Prior, was reopened on Friday after restoration. The east end, which was giving way through failure of the foundations, has been underpinned. The walls of the north aisle were so much bulged and out of upright that it was found necessary to rebuild them, and new windows, with traceried heads, have been put in. A vestry has been added. The parapet of the tower has been restored, and the timbers of the spire strengthened and reshingled. The wooden porch on the south side has been removed, and a new stone porch erected in its stead. The old wooden porch has been re-erected as a lych-gate on the south side. The pews have been removed and chairs substituted for them, and the floors of the church have all been taken up and the surface concreted. The modern nave roof has been much improved, and the roofs of the chancel and south aisle have been repaired. A new open timber roof takes the place of the modern plaster ceiling of the tower, and provides a ringing chamber for the bellringers, who hitherto have had to ring the bells, six in number, from the floor of the chancel, by the side of the organ, which is now removed to the other side. The 14th century font has been placed upon a step, and a new pulpit of oak, upon a stone base, has been provided. The whole of the work has been carried out from the plans of Mr. J. L. Pearson, R.A., architect, by Messrs. Cornish and Gaymer, of North Walsham. The cost has been between £4,000 and £5,000, nearly the whole of which will be borne by Mr. John Corbett, Impney, who expended about £1,500 upon the former restoration and repairs of the church in 1864.

Thrybergh.—The dedication of the rebuilt tower and spire of St. Leonard's Church, Thrybergh, took place on Friday. The foundation-stone of the work of restoration was laid on December 11, 1894. The architect has been Mr. C. Hodgson Fowler, F.S.A., of Durham, and the contractor Mr. R. Snell, of Rotherham. The cost of rebuilding has been about £800. The demolition of the old tower settled a point which was previously obscure, as regard the Norman church on whose western gable that tower was partly reared. That western gable was known to have been, previous to the restoration of 1871, a solid wall; the work of cutting the lofty tower arch was felt at that time to be one of great risk. Behind the jamb of the modern arch the old bolt hole, into which the wooden bar was shot when the door was opened, was recently discovered; the little Norman church had thus, in close proximity, a northern, southern, and western door. The date of the lower stages of the tower had been known to be Early English, and not Saxon, previous to their demolition, by the fact that the eastern wall was built on the gable of the previously-existing Norman church; but this proof was clinched by the bits of broken Norman carving which were found used up in the lower walling. The spire had a marked inclination, explicable by the fact that the tower had no foundation; and at the south-western corner the plinth had sunk to some extent. The new tower is of increased width, and the total height of the spire is now 86ft., the old one having been only 74ft.

CHIPS.

An infectious diseases hospital is in course of construction for the Blaby Rural District Council. Mr. Simpson is the architect, and Mr. Jewsbury the builder. The outlay will be about £4,000, inclusive of site.

The Roman Catholic church of St. Nicholas, in Pennywell-road, Bristol, will be consecrated on Thursday in next week. The nave was built in 1850, and the chancel, Lady-chapel, and sacristy, with the adjoining rectory, were added in 1873. An altar and other works have now been carried out, the style of the group of buildings, including church, rectory, and schools, being Early English.

The contract for the extension of Plas Mawr, Conway, the home of the Royal Cambrian Academy, has been let to Mr. Thorpe, Llandudno. The works are being carried out from the designs of Messrs. Baker and Hughes, London and Bangor, the honorary architects to the institution. The sale of pictures has been good, and the number of visitors shows a marked excess as compared with this time last year.

A public fountain has been erected on the parade at Lostwithiel, in commemoration of the opening of the corporation's works of water supply. Inclosed within a concrete basin, and having its rim coped with various coloured stones, the fountain stands on a rockwork of white and tinted local spar stones, with a Portland stone base, inscribed on it its four sides. On this is fixed the fountain, some 5ft. high, of glazed coloured imperishable Doulton ware, in relief. There are two basins, the lower supported by a column, circular in shape, and the whole work stands over 7ft. high. Mr. A. E. Skentelberry was the architect, and the contractors were Messrs. Whetter (plasterer), Bassett (mason), and Bennett (plumber).

NEW MARGARINE WORKS, SOUTHALL, NEAR LONDON.

THE NEW MAIN LINE TO LONDON.

SATISFACTORY progress has already been made in the construction of the Manchester, Sheffield, and Lincolnshire Company's extension to London. By the courtesy of the contractors of the Rugby and Woodford section (Messrs. Oliver and Son), a number of Press representatives were enabled on Tuesday to go over the sixteen-mile length now in course of construction between the places named; and as this section is probably the most important in the Midlands, owing to the heavy engineering works involved, a very fair estimate was obtained of the magnitude of the task, and the rapid and substantial manner in which the line is being constructed. The new line is of considerable importance to Birmingham, inasmuch as when the Birmingham and Stratford-on-Avon Railway is made there will be opened up another and important route to London, much shorter than the Great Western and Midland, and about the same as the London and North-Western, with the advantage of arriving in London at a central terminus—the Edgware-road. The route from Birmingham to the Metropolis will be by way of the new line to Stratford, where connection will be made with the East and West Junction Railway, along which the traveller will proceed as far as Woodford Junction, just beyond Byfield, thence on the Manchester, Sheffield, and Lincolnshire new line to Quainton-road and on to London, the latter part of the journey being partly accomplished over the Metropolitan system.

The main line in course of construction starts from the Manchester, Sheffield, and Lincolnshire Company's junction at Annesley, and runs to Nottingham, Loughborough, Leicester, Butterworth, and Rugby to Woodford, thence to Quainton-road, where it joins the Metropolitan. Just before entering London a new line will be constructed through St. John's Wood to the terminus. The length of the new line between Annesley and Quainton-road is 92 miles, and for purpose of construction is divided into several sections. Messrs. Oliver and Son's portion, from Rugby to Woodford, was commenced by them at the beginning of the year. Two-and-a-half years is the stipulated time for completion—none too long considering the enormous amount of work involved, especially at the Rugby end, where the line crosses the Oxford Canal and runs along a high embankment, afterwards crossing the North-Western Railway by means of a girder bridge having a span of 210ft. The line then passes over several sidings at that spot with another span, and enters a deep cutting through Rugby. From this cutting over a million and a half tons of earthwork are being removed. The line also crosses the railway from Leamington to Daventry by a girder bridge, thence continuing its course south to Catesby. At this spot the heaviest engineering work has been encountered, consisting of a tunnel 3,000 yards—about one mile and three-quarters—in length, constructed at a depth of 120ft. Between thirty and forty millions of bricks are being used in the tunnel. Ten shafts 15ft. wide have been sunk at various points on the route, and in each of them large numbers of men are working in day and night shifts. The country around Catesby, Cherwelton, and Woodford has undergone a very remarkable change. Hundreds of temporary wooden houses and buildings have been erected to accommodate the large army of bricklayers, masons, navvies, and labourers, together with their wives and families. Schools, mission-halls, dispensaries, and supply stores abound. Between Rugby and this spot upwards of two thousand men are regularly employed, and it is computed that along the entire route about ten thousand men are engaged. The Woodford section comprises the construction of six viaducts and about fifty bridges, besides the Catesby tunnel and the heavy works at the Rugby end. There are to be several large stations on this length, including one of a commodious kind at Cherwelton, and at Woodford a double connection, north and south, with the East and West Junction, by means of sweeping curves, the main line passing at right angles beneath. The work is well in hand in this district, the foundations of the bridges and stations being laid, and in some cases half the structures erected. Good progress has also been made in the construction of the Catesby tunnel. The material to be dealt with is a kind of sandy marl, and the workers are not much troubled with water. Blasting operations are carried on in the tunnel, which is being completed in 15ft. lengths, men working right and left of each of the ten shafts, consequently work is being pushed forward simultaneously at twenty different places. The men work by the aid of powerful paraffin lamps. The inside of the tunnel is being cased with best blue brick. A number of steam navvies are working in the cutting, loading the waggons at the rate of one every two minutes, each with about six tons of earth. The section beyond Woodford to Quinton-road (26 miles) is a comparatively light one, there being few engineering difficulties. Messrs. Scott and Co. are the contractors engaged, and are pushing on the work vigorously. Operations are also in progress at the London end, the spur to the terminus necessitating the demolition of a large number of houses. At Leicester a large and handsome station is to be built. The line has been planned to accommodate a very extensive traffic, particularly of goods and coal, from the North of England to the Metropolis. All the works are of the most permanent and substantial nature, the platforms and sidings will be ample, and the stations commodious. Sir Douglas and Mr. Francis Fox are the engineers of the southern section, Mr. Edward Parry being engineer of the northern portion.

BOOKS RECEIVED.

A Practical Treatise on the Manufacture of Bricks, Tiles, Terracotta, &c., by CHARLES THOMAS DAVIS. Third edition, illustrated (London: Sampson Low, Marston, and Co., Ltd.)—This comprehensive volume, which we noticed some years ago, has been revised and considerably enlarged. The author's work has been the chief treatise on the subject in the United States, and to this cause must be attributed the rapid sale of first two editions. The author deals with the subject from an American point of view; but, for all that, his work will be found of value by all manufacturers of brick, tiles, and terracotta. The subject is thoroughly handled. "The History of Brick" precedes chapters on "Building-Brick Clays," "Making and Burning a Kiln of Hand-Made Bricks," "Manufacture of Tempered-Clay Bricks," "Pressed and Ornamental Bricks," "Kilns," "Fire-Bricks," "Enamelled Bricks," "Architectural and Sanitary Ware," &c. The most modern machinery, kilns, and appliances are described and illustrated, and the engravings are numerous and well drawn. The student of clays and brick and terracotta will find Mr. Davis's treatise exhaustive of every kind of manufacture—from paving-brick to mosaics and enamelled tiles—and the various processes for handling, disintegrating, tempering, and moulding the clay and burning are fully entered into.

CHIPS.

At the last meeting of the Western Norfolk highways committee, held at Lynn, Mr. John Marshall resigned his position as surveyor of the Walton district, he having obtained another appointment, and Mr. Thos. Brown, of Colchester, was appointed in his stead. There were 63 applications for the post.

The examiners of the House of Lords had under their consideration, on Monday, several unopposed provisional order Bills providing for the acquisition of land for the enlargement of Richmond Barracks, Dublin, and for the extension of the boundaries of Bridgwater, Wakefield, and Keighley. The examiners found that the standing orders had been complied with.

A serious fire broke out, on Monday evening, at Mildmay-grove, Stoke Newington, upon the premises of Mr. T. J. Sole, builder. Builder's workshops of two floors, 30ft. by 20ft. in dimensions, were destroyed.

The intimation has been received in Aberdeen of the death, at Melbourne, of Mr. Mathew B. Jamieson, A.M.I.C.E., son of the Rev. Dr. Jamieson, Old Machar. The deceased, who was only in his thirty-fifth year, served his apprenticeship in Aberdeen as a civil engineer, under Mr. Boulton, burgh surveyor, ultimately acting as assistant. After serving in British Guiana, in the Public Works Department, Mr. Jamieson proceeded to Australia, where he carried out many mining and railway schemes and the construction of waterworks.

The New York Observatory at Lake Geneva will be ready for use at the beginning of September. The building has been constructed of grey Roman brick, with grey terracotta and stone trimmings, resembling in its form a Roman cross, with three domes at its extremities. The principal dome contains the 40in. telescope, the other two are fitted up with the 12in. and 16in. telescopes which are at present used at Kenwood Observatory.

OBITUARY.

Mr. JOHN COLSON, F.R.I.B.A., the architect to the Dean and Chapter of Winchester, died at his residence in that city on Tuesday week from a paralytic seizure at the advanced age of 75 years. He was the son of the late Mr. John Colson, of Hall-place, Shedfield, Hants, and was articled to Mr. Owen B. Carter, of Winchester, the well-known architectural draughtsman, where he was a fellow-student with the late Mr. George Edmund Street, R. A. Mr. Colson commenced independent practice in that city, but soon removed to London, and in 1855 returned to Winchester, where he had a considerable practice both in ecclesiastical and secular work. About thirty years ago he was appointed architect to the Dean and Chapter of the cathedral, a post which he held until his death. He had restored or built 120 churches in the diocese, a great many schools, and also designed the training college and Shedfield Church, close to which many members of his family and his wife, who died last January, rest. In connection with the cathedral he supervised the restoration of the Perpendicular west front, and the great repairs on the south transept. He was a staunch Conservative, and had formerly sat in the town council. He was an antiquary, and a capital florist and horticulturist. For many years he had been in partnership with his son, Mr. John Barnes Colson, F.R.I.B.A., who succeeds to the practice. He had been a Fellow of the Royal Institute of British Architects since 1858.

Two wealthy and philanthropic Scottish shipbuilders, Mr. CHARLES MITCHELL, LL.D., of Sir W. G. Armstrong, Mitchell, and Co., and Mr. PETER DENNY, LL.D., of William Denny and Brothers, Dumbarton, died on Thursday in last week. Curiously enough both were born in 1820, and were consequently 75 years of age. Among the special gifts of Mr. Mitchell may be named the church of St. George, Jesmond, Newcastle-on-Tyne, built in 1888-90 at a cost of nearly £30,000, from designs by Mr. T. R. Spence, of Newcastle, and the extension of the buildings of Marischal College, Aberdeen, a work now in progress, from plans by Mr. Mackenzie, of Aberdeen, at a cost of about £30,000. Mr. Denny's gifts to Dumbarton include the Levengrove Public Park and Knoxland-square. A statue of Mr. Denny, to be erected at Dumbarton, is now in hand for subscribers, the sculptor being Mr. Hamo Thornycroft, R.A.

ON Wednesday evening Mr. J. B. MARSH, architect, of Dudley, was descending a hilly road leading to Dartmouth on a pneumatic safety bicycle, when he lost control of the machine, and on reaching the bottom was thrown violently against a high wall. He was very seriously injured about the head, and was removed to the Cottage Hospital, where he succumbed to his injuries shortly afterwards. Deceased, who was between 40 and 50 years old, was visiting Dartmouth with his wife and family for the regatta, and only arrived in the town on Tuesday.

◆

At the Woodbridge sessions on August 21st, Edmund Capps, builder, Mill Hill, Middlesex, was charged on the information of Mr. George S. Horton, surveyor, of Felixstowe, with non-compliance with the by-laws of the Felixstowe urban district council, by not giving notice of completion before occupation in one case, and in another by not causing proper ventilation to be provided for the soil-pipe of a w.c. He was fined the full penalty of £5 for not providing the soil-pipe, and costs, £3 2s. For not giving notice of completion before occupation the defendant was fined £1 1s., and costs 9s.

A number of master painters and workmen have met in Southampton, under the presidency of Mr. Doggrel, with the view of promoting some form of technical instruction in house-painting and decorating. Mr. Fussell read some correspondence between himself and the Hartley Institute Council. The meeting came to the unanimous conclusion that technical classes for house-painters and decorators were necessary; that the matter should be pushed forward at once; and that a public meeting of the trade be called at an early date for that purpose.

At Glasgow Dean of Guild Court on Friday, authority was given to the officers of the 1st Lanark to erect headquarters on the south side of West Princes-street, Glasgow, in place of an old hall destroyed by fire some time ago. The new buildings are to consist of a large hall 120ft. long by 69ft. wide, having an arched roof supported by iron girders, and two tenements four stories in height, to be used as regimental offices, officers' and sergeants' mess-rooms, with sergeant-major's house. The buildings will cost about £10,000.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the Building News, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to The Strand Newspaper Company, Limited.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two, the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front-page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No Front-page or Paragraph Advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page Advertisements and alterations in serial advertisements must reach the office by Tuesday morning to secure insertion.

Situations.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is One Shilling for Twenty-four Words, and Sixpence for every eight words after. *All Situation Advertisements must be prepaid.*

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., LI., LIII., LIV., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., and LXV. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

Received.—G. S. and Co.—W. R.—M. Jacobs.—J. P. W.—Interested.—E. T. (Truro).—F. P. and Co.

Correspondence.

THE DURHAM AND LYNN COMPETITIONS.

To the Editor of the Building News.

Sir,—There is a letter in your issue of the 23rd inst., signed by "One Disgusted with Competitions through His Experiences at King's Lynn," in which the writer says that Messrs. Tree and Price won the Lynn competition in such a way as to disgust him. And he then goes on to insinuate that the accepted design was premiated because it had an ornate elevation, and that this was unfair because the work could not be executed for the stipulated sum. I feel that this imputation is so unfair to Messrs. Tree and Price, and also to the Lynn corporation, that I am bound to tell "One Disgusted," &c., that he displays absolute ignorance of the facts of this case.

This is really what transpired: The first premium was awarded to the design marked "It Speaks for Itself" for its all-round merits, but subject to its authors being able to obtain a *bonâ-fide* tender within the cost laid down in the conditions to competitors. The quantities were taken off, and public tenders invited. Fifteen tenders were received, seven of which were well within the stipulated cost, and not one of them was 10 per cent. above it. The work was immediately started (now some months ago), and we expect the building to be completed and open by Christmas next.

I fail entirely to see anything in all this which justifies the strictures of "One Disgusted," &c., on the successful architects, and I trust "One Disgusted," &c., will have the good taste now to be as ready with his apology to our architects as he was with his condemnation.—I am, &c.,

E. J. Silcock, Borough Engineer.

Borough Surveyor's Office, King's Lynn,
August 27.

Sir,—We should like to draw the attention of the other competitors in this latest piece of competition jobbery to the following fact, which seems to have escaped their notice:—Messrs. Barnes and Coates were *not* placed second by the assessor. This we have on unquestionable authority. As a consequence, some hard-working competitor has been swindled out of his well-earned second premium.

We shall be glad if you will kindly give this letter space. Surely it is about time architects combined to put a stop to this form of shameless jobbery.—We are, &c.,

Treadwell and Martin.

2, Waterloo-place, Pall Mall, S.W., Aug. 28.

ASSISTANT SURVEYORS IN THE WAR DEPARTMENT.

> "For who would bear . . . . .
> The insolence of office, and the spurns
> That patient merit of the unworthy takes?"

Sir,—For the benefit of any of your readers with any professional self-esteem who may aspire to become assistant surveyors in the War Department, I will tell a tale of what mine own eyes have witnessed.

Upon Imtarfa Hill in Malta, which commands the surrounding country much as the Acropolis crowns Athens, a vast group of new barracks is being erected at an estimated cost of nearly half a million of English money.

It was to be expected that advantage would be taken of such a site and opportunity to construct a monument worthy of her Majesty's reign, and of which a travelling Englishman might feel proud—considering that labour and excellent building stone is so cheap in Malta that the most elaborate masonry only costs about 9d. per foot cube, measured nett in the work when set.

Yet this is what has happened: Small sketch plans to $\frac{1}{8}$in. and $\frac{1}{16}$in. were prepared at the War Office, showing the proposed accommodation of the various buildings, and an assistant surveyor was detailed to Malta to elaborate the working drawings. This gentleman, who is a competent designer, naturally thought the one chance of his life had come, and hoped to be able to distinguish himself.

A series of petty contracts have been made with the native workmen for the erection of the buildings, to be measured up to schedule as the work proceeds.

The superintendence of the building was put in the hands of a captain R.E., whose fittest claim to such a responsible post was that he had had some experience in electrical engineering; but who esteemed himself able to carry out these works from the original sketches without any *professional* aid, and accordingly told the assistant surveyor that working detail-drawings were quite unnecessary, and dispensed with his services.

The captain R.E. then collaborated with the native workmen wherever details were required as the work proceeded, and the result naturally has been a series of abortions of designs and botches of construction, absolutely shocking to a professionally-trained man. The local authorities were, however, so proud of their work, that a series of official photographs was taken of the first buildings erected, and forwarded to the War Office for admiration.

The letter acknowledging their receipt asked some ugly questions as to variations from the original sketches, and complimented the colonel commanding the Malta station on having perpetrated a series of architectural atrocities "unworthy even of a barbarous nation," to reproduce the actual wording of the letter.

However, when I was in Malta a few months ago, the same system obtained, and the assistant surveyor had been relegated to a desk in a petty divisional office, so that evidently the gentlemen who direct the fine art department at the War Office are quite unable to quicken the æsthetic perceptions of even a colonel-commanding. "Corpus est delendum."—I am, &c.,

Traveller.

THE PULPIT AT ST. MARGARET'S, WESTMINSTER.

Sir,—In some notes upon the Canary Isles last week I referred to the painted oak pulpit at the above well-known church as designed by the late Sir Gilbert G. Scott, R.A. Of course, I knew the very beautiful font at the western end of the nave was made from Mr. John P. Seddon, F.R.I.B.A.'s, design, but was under the impression the rest of the new work was the late Sir Gilbert's. A courteous and esteemed correspondent has just pointed out to me that the pulpit in question was not included in the general restoration scheme, but was added some time afterwards as a memorial to the late Mr. Vacher, of Parliament-street, S.W., and was designed by his nephew, Mr. Sydney Vacher, A.R.I.B.A., architect, of 35, Wellington-street, Strand, W.C., an old pupil of the late Mr. G. E. Street, R.A. I am glad of an opportunity to make this correction.

Of course, when the wonder was expressed as to whether other painted pulpits existed in this country, I did not refer to ancient (generally stone) ones, such as the well-known 15th-century one at St. Saviour's, Dartmouth, for instance. The reference was made to modern oak ones.—I am, &c.,

Harry Hems.

Fair Park, Exeter, Aug. 26.

CHIPS.

The rural district council of Winchcomb, Gloucester, have called in Mr. J. E. Willcox, C.E., of Birmingham, to report and advise on schemes of water supply for the villages of Gretton and Guiting Power.

The new technical school at Accrington, built for the corporation from plans by Messrs. Morley and Woodhouse, of Bradford, selected in competition, was opened on Wednesday.

The sill of the Canada dock entrance to the northern docks at Liverpool has been deepened to 14ft. below the old dock sill, thus rendering it adequate for the largest vessels frequenting the port. In a few months' time the Canada dock itself, which is also fast approaching completion, will be finished. By the opening of the new lock the west side of the Canada dock has been thrown open, together with its new sheds and quayage conveniences, for immediate traffic.

On Monday the extensive granite quarries at De Lank, near Bodmin, were reopened for active work in the presence of a representative company interested in the prosperity of the county. Mrs. Rundle Cornish, wife of the Archdeacon of Cornwall, gave the final turn to the turbine wheel which started the hydraulic machinery recently fitted up for dressing, moulding, and polishing the granite. The granite from these quarries was selected by Sir James N. Douglass, engineer-in-chief to the Trinity House, for the new Eddystone and other lighthouses, and by Mr. Wolfe Barry, C.B., for the Tower Bridge.

The picturesque city of Udaipur, with its lake palaces, can no longer boast of being the most inaccessible capital of India, for it has just been connected with the railway system of the peninsula. The Bombay, Baroda, and Central India Company began the working of the branch line from their station at Chitor to Debari, eight miles from the city of Udaipur, to which it will ultimately be extended, on the 1st inst. The line—$60\frac{1}{2}$ miles in length—was made in little more than a year, and at a cost—28,000 rupees per mile—which makes it one of the cheapest-built lines in India.

On Friday, Dr. R. Deane Sweeting, Local Government Board Inspector, conducted an inquiry at the town hall, Hinckley, into an application for a loan of £4,000 for the purchase of land and erection of permanent buildings to be used as an infectious hospital by the Hinckley urban and rural district councils. Messrs. Simpson and Harvey, of Leicester, are the architects, and the plans, which are estimated to cost £3,200 in execution, and will provide twelve beds, besides observation ward and administrative block, were described by Mr. Simpson.

An inquiry, ordered by the Local Government Board into the joint application of the corporation of Richmond and the district council of Heston and Isleworth for leave to borrow £5,000, for the establishment of a joint isolation hospital, was held on Tuesday and Wednesday before Dr. Theodore Thompson, the inspector appointed by the board. The site for the proposed hospital will cover an area of about $9\frac{1}{2}$ acres, at Mogden, near the Isleworth sewage farm, and the scheme has been oppposed by an adjoining landowner and by the Twickenham District Council.

An anonymous donor has presented to the city of Liverpool a piece of land at Wavertree, an eastern suburb, expressing the wish that it should be mainly devoted to the purposes of a children's recreation ground. The area includes several large residences, the rents of which will form a fund towards the maintenance of the recreation grounds. The total area is 108 acres.

The Manchester Art Gallery Committee announce that the private view will take place on Monday next. In the work of hanging, the committee have been assisted by Mr. George Clausen, A.R.A. A feature of the exhibition will be a fine collection of sculpture. Sir F. Leighton will be represented by two of his recent works.

Intercommunication.

QUESTIONS.

[11403.]—**Estate Management.**—Can any of your correspondents give the names of any books which treat of the laying-out of building estates, the formation of streets or roads, and other matters connected therewith? Also, of any which give the powers and usual requirements of town authorities in Scotland, and the rights of proprietors in respect of such matters?—Z. Y. X.

[11404.]—**Marks and Brands.**—Will some reader tell me where I can get an up-to-date list of distinguishing brands on timber, deals, battens, and flooring-boards, &c.?—Seaside.

[11405.]—**Setting of Pencil Sketches.**—Will any reader who has had considerable experience in pencil-sketching inform me what is the best method of setting sketches to prevent them from rubbing? I have tried weak mixtures of gum and water, milk and water, and covering them with a light wash of colour, such as yellow ochre, but none of these seem entirely successful.—E. C. B.

[11406.]—**Study.**—I should be extremely obliged if any of your numerous readers would kindly give me any information on the following:—I was articled to an architect and surveyor, and with him four years; am now in a builder and contractor's office, where I have been for two and a half years, and shall stay till end of year, so as to complete my three years Which do consider the best to follow as a vocation—to remain in a builder's office, or go into an architect's office again? I do not mind the office hours, so long as I shall eventually be able to secure a good situation. Am well up in drawing, specifications, and quantities; and, of course, am now gaining the practical knowledge. Should like to know this, so as to be able to decide what course of study to take up this winter. I may mention I have passed first class in both Elementary and Advanced Building Construction, also Geometry (Science and Art Department). Any information and advice will be gladly received by—Undecided.

[11407.]—**Cast-Iron Pipe Sewers.**—How should cast-iron pipe sewers be jointed? I should like a model specification clause?—Drain.

[11403.]—**Church Screens.**—Where can I find details of old rood-screens of wood? A reader may oblige.—Old Subscriber.

[11409.]—**Joining Columns.**—How are columns supporting floors of warehouses best joined? Are there any details published of such construction? Any information would oblige.—A. S. T.

[11410.]—**Electric Railway Tunnels.**—Which are the principal tunnels in England on this system, and dimensions and mode of construction adopted?—Enquirer.

REPLIES.

[11395.] — **Concrete Arching.** — In reply to "Sigma's" query, asking for the results of experiments on the strength of Portland cement concrete in the form of arching, allow me to suggest that he apply to Mr. P. Stuart, F.R.S.A., who has carried out a large number of very important and exhaustive experiments in connection with concrete arches, and also slabs. He will, I am sure, give him very valuable information on this subject. Mr. Stuart's address is Regent's Dock, Limehouse, E.—A. W. Haynes, C.E.

[11399.] — **Rolled Joist.** — In Replies, Aug. 23, "G. H. G." states Hurst's formula to be four times depth × area below centre of gravity divided by lengths in feet; but Hurst says: constant for rolled girders 7, constant for T-girders 4. Ought it not to be 7 times depth, &c., and not 4 times, as given by "G. H. G."? As this makes a very great difference, may I ask "G. H. G." which is the correct constant to be used?—X.

[11401.]—**Warehouse Floors.**—"Zero" does not give any precise information as to the purpose of the warehouse or size of floor. Many differing data are given, but some reliable authorities allow 2½cwt. per superficial foot, including weight of floor itself, as sufficient.—G. H. G.

[11402.]—**Mortar.**—A rod of brickwork requires about three cubic yards of mortar, and about 4,350 stock bricks. One authority says a rod of brickwork requires one yard cube of stone lime and 3½ yards cube of sand. In another place the same compiler says a rod of brickwork contains about 235ft. cube of brickwork and 71ft. cube of mortar. "Beginner" may take which he likes, but the first statement is about right.—G.

At the Watford petty sessions, on Tuesday week, a sawmills labourer, named John Gulston, was committed for trial on a charge of unlawfully wounding his employer. Mr. James Waterman, builder, of Watford. Prisoner, who had been in prosecutor's employ for 12 years, was recently reduced in position, and on being given an order by his master, is alleged to have struck him several violent blows on the head with a cart prop, rendering him unconscious. Mr. Waterman has since suffered greatly, and gave his evidence while seated.

Mr. Thomas Codrington, M Inst.C.E., Local Government Board Inspector, held an inquiry at the District Council Offices, Eastleigh, on Thursday in last week, with reference to the borrowing of £1,000 for the purpose of laying-out a recreation ground, four acres in area. Mr. Galbraith, surveyor to the district council, explained the proposal. A second inquiry followed before Mr. Codrington as to an application to borrow another £1,000 for works of surface drainage to be carried out in the Winchester-road. Mr. H. J. Weston, of Southampton, is the engineer.

Legal.

COMPULSORY SALES.

When a railway company has to purchase land under its compulsory powers, it naturally desires to buy as little as possible. On the other hand, the owner of the land which the company would like to buy prefers to sell as much of it as he can make them take, and this is especially the case where there are buildings and a business to be considered. Section 92 of the Lands Clauses Act, 1845, enables the owner who is served with a notice to treat for a portion of his land to serve a counter-claim that they shall buy the whole. This section, indeed, provides that no party shall at any time be required to sell to a railway company a part only of any house or other building or manufactory if such party is willing to sell the whole. In a recent case, before Mr. Justice Chitty (*Times*, July 26), in a dispute with the Manchester, Sheffield, and Lincolnshire Railway, the point to be determined was whether a building which the railway wished to buy by itself was, or was not, a part of a manufactory, so as to compel the company to take the whole. It appeared that the building for which the railway gave notice to treat was occupied on the ground floor by tenants of the owner of the adjoining factory; but that a portion of the upper floors was used by them for the purpose of their manufactory. The owner declared they needed these floors, and that to take the land which the company wanted would interfere with them seriously in the way of their business, and they, therefore, required the company to buy the whole.

The learned judge held that it was not necessary to prove that the part which the company wanted to purchase was actually a portion of the factory. The land and buildings thereon must be looked at as a whole, and, so regarded, he thought it clear that they were all used together for the purposes of the factory. When a railway company proposed to take a part of a building, part of which building was used as a manufactory, they were in substance claiming to take a part of the manufactory, within the meaning of the Act. In this case, therefore, as part of the building which the railway desired to purchase was used with the owner's factory, the whole of this building was really a part of his factory, and so could not be taken by itself under the compulsory clauses as he was willing to sell the whole, and which the company will now have to purchase.

Fred. Wetherfield, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

Note.—All questions for reply in this column must be headed "Building News," and must reach my offices, as above, by *Tuesday* morning to insure answer same week.

The Kent County Council, at their last meeting, referred to a committee a proposal for the erection of a high level bridge over the Medway between Halling and Wouldham. Towards the estimated cost of £24,000 for the bridge, and £10,000 more for the approaches, the Rochester Bridge Wardens offer a grant of £12,000, and the residents in the district £10,000.

It was recently decided to restore three well-known North Riding parish churches, which had become dilapidated. The works at the 13th century edifice at Grinton are approaching completion. The lead has been taken off the church, and has been re-melted for use on the new roof. At Carlton Miniott upwards of £1,000 is to be spent in rebuilding the church, which dates back to the 12th century. Carlton-in-Cleveland church, which was burned down 14 years ago after having been restored, is to be rebuilt, and a restoration fund has been opened by the new vicar. Some £2,000 is to be expended on the work.

For some time past the old Grammar School in the Wakefield Borough Market has been undergoing considerable alterations and improvements, with a view to the structure being used as a boys' school in connection with the cathedral. The work, which has entailed an expenditure of about £1,200, raised by subscription, has been carried out under the superintendence of Messrs. Simpson and Richardson, architects, by whom the plans were prepared. The large schoolroom and south classroom have been completed, and were opened on Monday last, but an assembly-hall and other rooms, as well as some outbuildings and the playground, are not yet finished. The lighting, heating, ventilation, and drainage arrangements have all been revised, and the school furniture is all new.

LEGAL INTELLIGENCE.

The Kensington-court Corner Buildings Once More.—At West London Police-court, on Saturday, Mr. Rose heard the summons issued by Mr. T. Chilvers, on behalf of the London County Council, against Mr. Robert J. Worley, of Wellington Chambers, Cannon-street, in respect of the building which he suffered to be continued above the permitted height at the corner of Kensington-court, fronting the main road.—Mr. Chilvers said he was instructed to call attention to two facts—one, that the defendant was cautioned in April, 1892, before the building reached the statutory height, and the other to a letter sent to him in February, stating that the Council would consider any reasonable modification of the building he might suggest. Mr. Rose: You cannot, by the Act, pull the building down? Mr. Chilvers: No, sir. Mr. Poole, who appeared for the defendant, asked how long the persecution of the Council was to last, and said it was admitted by the judges and counsel that it was a hard case. The building, as it stood, injured no one, but added to the rates of the parish. He regretted that there was no power to pull the building down. If there had been, he could have gone to a higher Court. Because it was a fine, he was obliged to submit to a decision in the Divisional Court. It was the first case under the Act, and the Council had effected their object by the decision as to the question of a corner site. The new Act was passed within a year, showing that the old Act was unjust. He could not suggest any reasonable way except of pulling the building down, which would entail an expenditure of £10,000, with a loss in the rental of £1,500 per annum. Mr. Rose: How high is the Palace Hotel? Mr. Poole: Half as high again as the defendant's building. If a new street had been formed at the side, the County Council would have cut the hotel down. (Laughter.) Fortunately for the owner, the hotel faced Kensington-gardens. My client ought not to be followed up and persecuted in this way. Mr. Rose fined the defendant 3s. a day for each of 74 days, with costs.

Damages Against a Surveyor.—Mr. Ald. Dodsworth, Deputy Sheriff, with a jury, sat at York Castle, on Friday, to assess damages in the case of Gilbert Benjamin Jackson and Francis Jackson, solicitors, Middlesbro', against James March, surveyor and valuer, Richmond. It was stated that in January, 1893, the defendant valued some property at Richmond at £580 10s., and on the faith of that valuation the plaintiffs in May, 1893, advanced £400, and there was now £462 6s. 5d. due for principal and interest. When the property was offered for sale by auction Lot 1 realised £145, and Lot 2 £141. A policy was given as additional security, the surrender value being £23. On those figures the plaintiffs claimed £154 6s. 5d. Mr. John Weatherall, auctioneer, Richmond, who offered the property for sale, considered that £150 was the outside value of Lot 1. The property was in bad repair, and had been condemned. It was valued at 16 years' purchase. The property did not depreciate between the time of the valuation and the sale. The jury gave a verdict for plaintiff for £125.

CHIPS.

The town council of Leominster have elected Mr. Ernest Bailey, at present chief assistant to the surveyor of Barton-upon-Irwell, as their surveyor from among 55 candidates.

The War Office have instructed Messrs. Paterson and Cooper to proceed with the erection at Netley Hospital of the Hermite sanitation plant, the cost of which has been provided for in this year's Parliamentary estimates.

A life-size statue of Dr. Martineau in white marble is to be placed in Manchester College, Oxford, in commemoration of the completion of his 90th year. The commission has been given by the committee to Mr. H. R. Hope Pinker, who has already had the requisite sittings from Dr. Martineau.

The consecration of the new Episcopal Church of St. Droston, at Insch, was performed, on Saturday, by the Right Rev. Bishop Douglas of Aberdeen. The church is in the Early French Gothic style, designed and carried out by Messrs. Ross and Macbeth, architects, Inverness, and commands one of the finest situations of the rising township on the north side of Commerce-street, along with a new parsonage. The church cost £1,700, and the parsonage £800.

Business at the Auction Mart, Tokenhouse-yard, reached its lowest point last week, when the aggregate was only £2,580, said to be the smallest on record, but two sales having been effected. A remarkable instance of the depressed condition of agriculture was afforded at the sale of Langdon Abbey, near Deal, on Friday, when 639 acres of land, with farmhouse, stabling, homestead, and seven modern cottages, only realised £5,700, or less than £9 an acre. Fifteen years ago the property was valued at over £20,000, and four years ago it was mortgaged for £14,000.

WATER SUPPLY AND SANITARY MATTERS.

Bowness Sewage Scheme. — On Wednesday week Mr. G. W. Willcocks, one of the inspectors of the Local Government Board, held an inquiry at the Institute, Bowness, in connection with an application by the district council for leave to borrow the sum of £4,000 for the purpose of sewage disposal, the scheme adopted by the urban district council being that known as the international process, and embodying the treatment of the sewage in upward-flow circular tanks, and its subsequent filtration through specially-prepared polarite filter-beds. Mr. G. Gatey, the clerk to the council, stated that the normal population of Bowness was 2,062, and the maximum summer population 4,500. It will be remembered that the Bowness district council figured some time ago at the Appleby Assizes, the result of that trial being that a limited time was allowed for the carrying out of a purification works. The council having visited and inspected many schemes, finally decided upon the international process as being best adapted for their district, Messrs. Lomax and Lomax, civil engineers, Manchester, being engaged to carry out the scheme.

Glasgow and the Purification of the Clyde. —The town council of Glasgow at their meeting on Monday advanced another stage in their great scheme for the purification of the Clyde by the interception of the city sewage, which was wont to pollute the river. At present the refuse from the eastern district is dealt with at the Dalmarnock sewage works, and the proposal before the town council was to similarly treat the sewage from the north and north-western districts, at works to be erected on corporation ground at Dalmuir. The sanctioning of the new scheme meant that all the sewage from that part of Glasgow to the north of the Clyde, or two-thirds of the city, would be dealt with, and that not only would the Clyde benefit, but the Kelvin as well. The estimate of cost of the scheme consisted of the following items:—For intercepting and outfall sewers, £250,000; for pumping station at Partick and sewage works at Dalmuir, £200,000; for various properties and way-leaves on the route between Glasgow and Dalmuir, £30,000; for the lands of Dalmuir, stated at the present ledger value, £122,000 — total, £602,000. Councillor Crawford, at a previous meeting, had moved that the council obtain the necessary Parliamentary powers to proceed with the scheme, and Treasurer Gray had moved an amendment that the matter be delayed meantime. The debate was resumed on Monday, when, after a long discussion, it was decided by 42 votes to 13 to proceed with the scheme forthwith.

Glossop.—Mr. J. W. B. Clerke, M.I.C.E., conducted a Local Government Board inquiry at the Town Hall, Glossop, on Tuesday last, respecting the application made by the Glossop Corporation for sanction to borrow £44,000 for works of sewerage and sewage disposal. The scheme submitted for the consideration of the Local Government Board includes the sewering of the entire borough, and also the carrying out of outfall purification works. The scheme has been prepared by Messrs. Lomax and Lomax, civil engineers, Manchester, and is calculated to deal with the sewage from a population of 30,000. The precipitation tanks will be on the continuous upward-flow principle, the effluent therefrom being passed through extensive polarite filter-beds. The application was opposed by Mr. Fox on behalf of Messrs. Potter and Co., of Dinting Vale Printworks, the contention of Mr. Fox being that the whole of the dye and bleach waste water should be admitted into the Glossop sewerage system, the corporation having refused to deal with this waste water on the grounds that it would injuriously affect the treatment of the sewage at the outfall works. Mr. Fox gave notice that if, in carrying out the scheme, the Glossop Corporation omitted to provide facilities for the reception of this waste water into their sewers, Messrs. Potter would then at once apply for a mandamus to compel the Glossop Corporation to do so. As this point is of vital importance to all local authorities, no doubt our readers will watch with interest the result of the proceedings, if any be taken.

The Talla Water Supply for Edinburgh.—The first contract in connection with the Talla Scheme was offered to contractors on Monday, a number of whom met Mr. Wilson, C.E., at his office, 72a, George-street, Edinburgh, in order to see plans and specifications, and hear explanations. The engineer has also arranged that his assistant shall meet intending contractors to-day (Friday) at Broughton, and go over the ground with them. The first contract will include a railway 8½ miles long from the junction with the Caledonian Railway about a mile east of Broughton Station to a point near the site of the proposed reservoir embankment across the Talla; the diversion of the road near Tweedsmuir village, which includes a bridge over the Tweed, of steel girders 100ft. in span and 15ft. wide, and a double line of 36in. cast-iron pipes across the valley of the Tweed, and partly along the line of the new road. The pipes will carry the water from the reservoir the first part of the way, and it is proposed to have them put in now when the new road is being made. The railway is chiefly for conveyance of material to construct the reservoir.

Wednesbury Sewerage Works. — Proposed Extension.—On Wednesday, Colonel W. Langton Coke, M.Inst.C.E., on behalf of the Local Government Board, conducted an inquiry at the Municipal Offices, Wednesbury, with reference to an application on the part of the town council for sanction to a loan of £7,500, for additional works of sewerage and sewage disposal. The amount already expended upon the sewage and outfall works has been £50,000. Prior to March, 1894, the attention of the corporation was called to the unsatisfactory state of the effluent from the sewage outfall works, and in September of that year a report was presented by Mr. E. Pritchard, recommending certain additions to the works. The council had gone into this matter with very great care, and had adopted the recommendation, but with a great deal of reluctance on account of the further expense which would be involved. They felt, however, that something further was necessary to be done. A rate of 1d. in the pound being £280, the annual repayment of the proposed loan, at 3¼ per cent. for 30 years, would be as nearly as possible 1½d. in the pound. The sewage farm at the present comprised 26 acres, and there was abundant room for any further extension, so that the scheme before the inspector did not include the acquisition of any additional land. The outstanding loans amounted to £71,381. Mr. E. Pritchard, the engineer of the existing works, said the sewers were constructed for a population of 30,000, with an estimated quantity of 25gal. of sewage per head per day, and the sewage purification works were designed to deal with a population of 25,000, or 625,000gal. per day, on the principle of intermittent downward filtration. That, however, he asserted, was an exploded idea, and the land, having become sewage sick, refused to do its work. Under those circumstances, he had advised the corporation to adopt a plan with polarite treatment as its basis. Councillor Davies said that when the works were laid down ten or twelve years ago, Mr. Pritchard stated that the scheme was sufficient to meet the requirements of the town for twenty years, but in a couple of years, with scarcely any house connections, the scheme was not fulfilling its promise, and when there was rain as much as 800,000gal. of water was delivered at the outfall works, whilst in dry weather the delivery amounted to 50gal. per head of the population. He suggested that only a part of the scheme should be sanctioned, so that the corporation might have three or four years in which to look about and consider what further extensions should be made. The Inspector said he thought this proposal should have been made at a council meeting; but he would make a note of it, and look into any papers which Mr. Davies might think fit to send him. Mr. Pritchard cited figures and passages from reports to show that Mr. Davies was speaking under a misapprehension. Councillor Joynson, chairman of the outfall works committee, said no such quantity as 800,000gal. ever reached the outfall works in 24 hours, as the records kept at the works would show. At the present time, with 4,306 houses connected (all but 200 in the town), the maximum delivery was not more than 600,000gal., and then only in times of heavy rains. The proposal to deal with the matter in the piecemeal manner advocated by Mr. Davies had been thoroughly discussed in committee and by the council, and the conclusion arrived at was that nothing less than what was put before the inspector that day would be sufficient to carry out the work properly. Mr. Duignan, in answer to the Inspector, said the Walsall, the West Bromwich, and the Wednesbury authorities, whose sewage outfall works were in the same neighbourhood, had been threatened, and had spent large sums to improve their respective systems so as to avert litigation. On the proposition of the Mayor, seconded by Alderman Kilvert, a vote of thanks was accorded the inspector, who said he thought he could best show his gratitude by getting the work through as soon as possible. He then went to inspect the works.

◆

The electric lighting committee of the Blackpool corporation have decided to recommend the town council to spend £30,000, in addition to the electrical works, before next season.

By way of marking the completion of the Cowlyd water scheme, which has been carried out from the plans of Mr. T. B. Farrington, C E., borough surveyor of Conway, Mr. Albert Wood, who was for several years the mayor of the borough, has erected in Castle-square a drinking fountain. It stands about 10ft. in height, and is surrounded by a bronze figure of Llewelyn the Great, bearing his armorial shield, and carrying an unsheathed sword. Around the base run the words—"Llewelyn Ab Iorwerth, founder Conway Abbey, A.D. 1152." The material from which the stonework was executed came from the Penmon limestone quarries, Anglesey.

Our Office Table.

Five fresh pictures have been hung at the National Gallery. One of these is simply transferred from South Kensington Museum, by which institution it was acquired in 1869, and was numbered 1356. This work, which is now numbered 1439, is hung in the north-west corner of Room XI. at the National Gallery, is entitled "Fishing in the River," and is by Saloman Van Ruysdael, of Haarlem, 1600-70, of whose work there is one other example in the collection. It is a small picture, 14in. high by 25in. wide, and shows a typical shallow and sluggish Dutch stream, with a well-wooded bank to the right, broken up by a timber bridge crossing a ditch, which runs into the main current. On the left in the foreground are five peasants, angling from a punt moored among the reeds, and over the distant fields are seen the inevitable windmill and church tower. Another work, placed in position on Monday morning, has been presented by Mr. Arthur Kay. It is a "Seapiece with Shipping," by Hendrick Dubbels, 1720-74, a Dutch painter not hitherto represented in the gallery. It is hung on the line in the opposite or south-eastern angle of Room XI., and is numbered 1462, and measures 16in. high by 12in. across. In a wide bay are seen several sloops and fishing smacks, one on the left just grounding to unlade on a sandy shoal. Overhead is a broad expanse of light blue sky flecked with clouds, and the reflections of these cirri and cumuli and the brown and white sails and blackened hulls of the vessels are reflected in the becalmed waters. In addition to these, three small portraits, lent by Mr. George Salting, were placed on the walls under the central dome on Wednesday.

An exhibition of old and modern china, glass, pottery, and antique and humorous art, which opens at the Westminster Aquarium on September 10, should be of much interest. Viennese glass and mosaics, Bohemian glass of artistic design and lavish colour, Dresden china, and Sèvres porcelain will make a harmonious whole; whilst many varieties of English ware will also be on view. Among the curious exhibits will be some monumental vases taken from the Chinese Emperor's palace at Pekin, which were at one time the property of General Gordon; and a number of the Nelson relics will also be shown.

The forty-second annual report of the Department of Science and Art of the Committee of Council on Education has just been issued. It is arranged under eight heads covering instruction in science and art. The number of science schools in 1894 was 2,602, with 9,433 classes and 183,120 students. The results of the May examinations showed that 103,396 individual students were examined, 188,773 papers worked, 82,406 papers passed, and 49,990 first classes awarded in elementary and advanced stages. The payments to science schools on the results of the examinations for 1894 amounted to £140,391, or £10,382 more than in the preceding year. During the year 20,206 elementary schools, with 2,155,311 scholars, were taught drawing and examined under the regulations of the Department. In addition, 16,842 pupil teachers and ex-standard scholars were examined in drawing, of whom 7,473 were successful. The grants for drawing in 1894 amounted to £159,072, in 1893 to £152,860. In 1894, 1,799 schools received "fair" awards, 13,462 "good," and 4,926 "excellent." Building grants were made in 1894 to Science Schools at Batley, Rochdale, Gravesend, High Wycombe, Skipton, Rochester, Battersea, Aston Manor, King's Lynn, Tiverton, Banbury, and Darwen, amounting to £5,314. The grants for buildings in the previous year were £2,251 12s. 6d. In the works submitted in architectural design, the examiner, Professor T. Roger Smith, F.R.I.B.A., refers to the fact that the numbers have diminished, saying the competition under the new syllabus has, however, very possibly not been quite so attractive to ambitious students as under the old arrangements, which approximated more closely to the conditions of actual public competitions as usually conducted by persons requiring designs for public or other buildings. The competition this year has been the means of obtaining a great deal of good and solid work, and less that is either extravagant on the one hand, or trivial and poor on the other hand than has been submitted in some former years, In building construction, the examiner, Colone

H. C. Seddon, R.E., reports there is again a large increase in the total number of candidates, being 501 in excess of last year, 1,296 in excess of 1892, and 2,061 in excess of 1891. The results in the elementary stage have been the most satisfactory, the drawing, as a rule, being far better than in the advanced stage, whilst the largest percentage of those drawing badly is to be found in the honours stage. The percentage of worthless designs was decidedly lower than in previous years, but this was no doubt chiefly due to the alteration in the system.

Two of the few remaining old houses in Wych-street are, we see, to be sold. These are situated on the south side of the street, and have some interesting remains of wood mouldings round the projecting bay windows, and the three upper stories overhang, and have gables. The fronts are framed and plastered, and are good specimens of 17th-century timber-framed work. They are at present untenanted, and to all appearances very dilapidated. Adjoining these are to be noticed two other houses, with old woodwork round the windows, but in a rather Later style. Sketchers and photographists of Old London may find their opportunity here, as in other parts of this locality.

Under the will of the late Mr. George Woofindin, of Sheffield, who left personal estate valued at £131,493, the executors are to stand possessed of one-third part of Mr. Woofindin's residuary estate upon trusts, to lay out such sum as the trustees shall think proper in the purchase of a site within the parish of Sheffield, and to erect thereon, furnish, equip, and endow such number of almshouses as they shall deem the trust fund sufficient to provide, to be called "The George Woofindin Almshouses." The executors are to stand possessed of the remaining two-thirds of the testator's residuary estate in trust to purchase within 20 miles of St. Peter's Church, Sheffield, a site, and to erect thereon, furnish, equip, and endow a convalescent home, to be called "The George Woofindin Convalescent Home," and, if the funds should be sufficient, to purchase also a site at some seaside place, and erect thereon, furnish, equip, and endow a "George Woofindin Subsidiary Convalescent Home." The plans for the homes and almshouses are to be obtained by public competition; but one of the executors, who is an architect, is not to be prohibited by his position as executor from competing.
